To us who are accustomed to seeing "Southern extracted" honey quoted in the honey markets at a very low price, the tendency is to make us believe that all honey from the South is of inferior quality. Mr. E. L. Horton, of South Carolina, has very kindly sent me five pounds of comb honey gathered from the locust; and I wish to say it is as fine a honey as I ever sampled, both in color and flavor. It certainly has that "morish" taste; and while I was not prejudiced against Southern honey, really I never expected such a fine article as the sample sent me. In this section we once in a while get a little honey from the locust, but nothing in the way of surplus; but what little comes in the hive is decidedly dark, and strong in flavor. Does "locality" explain the difference, or is there a difference in the kind of locusts? Just as I finish writing the above, I note that friend Buchanan, of Tennessee, says that the locust is one of his best sources of honey, and that the honey is water-white, and of fine flavor—assuredly a splendid description of the honey sent me by Mr. Horton.

* * *

Major Shallard says, Dec. 15, p. 797, that a good strain of Italians will not lay above the brood-nest. If he means that, in an ordinary eight or ten frame Langstroth without an excluder being used, a queen of a "good strain," as he calls it, will not go above in an extracting-super, then most assuredly I want none of that good strain in my yards. In the past I have had some that would act just that way, judging by their record at laying eggs; and such a queen would be decapitated just as soon as her peculiarity was noticed. No, sir; in this country, at least, where rapid building-up in the spring is not only desirable but simply *imperative*, we must have

queens so prolific that they would at once skip above for more room if the apiarist did not in some way give them more room than an eight-frame Langstroth hive affords. It is needless to say, I think that all extracted-honey producers should use excluders; but that does not forbid giving a prolific queen more room than the brood-nest allows, as it is a very simple matter to hoist brood above, or give an extra story for brood-rearing till the main flow opens.

* * *

The joke is on the editor. After publicly inviting Dr. Miller to "jab" me because of my slighting the editor's pet theory, the so-called "winter nest," the said doctor ends his "jabbing" with the words, "for practical purposes the Canuck holds the safer ground." The editor having received punishment already, I will just ask Dr. Miller one question, and drop the subject for the time at least. He says, page 74, Feb. 1, "Your experiment will prove nothing, for, as ye editor suggests, the minute you stopped feeding them they began scooping out a winter nest." Now, then, doctor, please remember that it was on Nov. 7 that the said colony had all combs *solid*, and that five weeks from that date we had weather about down to zero. How much of a "nest" could they "scoop" out of those solid combs in five weeks? You know as well as or better than I do that very few stores are consumed early in the winter when no brood is in the hive; but please say whether you think enough empty comb will be in evidence in five weeks to accommodate even one quarter of the bees. Talk about overstocking the country with bees—really this matter of advising full combs in the fall would be the greatest factor toward that end that could be imagined *if* all beekeepers in the North who winter outdoors would follow the plan. But you needn't worry; they will not do so, as it is too much trouble, and often too big a pull on the purse—at least those are the reasons that prevent this scribbler from putting all colonies in that condition every fall.

* * *

Dr. Miller asks me to state what temperature I would prefer for a straight "five-months pull" in outdoor wintering. I don't know, but rather suspect that the *changing* temperature we have is about right, as with proper preparation bees generally winter well under these conditions. No, I do not believe that brood-rearing starts earlier outdoors because it is colder than in the cellar. Generally speaking, the best cellar for wintering bees is one in

which the bees will be very quiet all the time, and, as a rule, little brood will be in the hive when the bees are taken out in the spring. There are exceptions to this rule, of course, but that does not nullify the rule. The steadier the cold weather outdoors, the less brood-rearing there will be; so, to my mind, the cause of brood-rearing, either outdoors or in the cellar, is "activity." When the temperature is 32 or 35 in the *shade*, it will register higher in front of the hives where the sun is shining, and that condition causes *activity* and consequent brood-rearing. Moderately cold steady winter weather gives best results in outdoor wintering, especially if too big a winter-nest (ha! ha!) is not allowed, so that the danger of the colony running out of stores *above* the cluster is avoided. If the colony is none too well provided with stores, then a warm spell now and then is imperative if the bees winter at all. Often such a colony will become stranded on empty comb during a prolonged cold snap, and will starve, leaving honey at the back of the frames.

* * *

VENTILATION FOR BEES OUTDOORS AND IN-DOORS.

On page 722, Nov. 15, 1912, Mr. Doolittle lays great stress on having entrances of hives in which bees are wintering outdoors so arranged that the bees will have an abundance of pure air circulating around the cluster. While in a measure I can endorse what he says, certainly it is a puzzle to me that, in another article of his regarding cellar wintering, he virtually claims that fresh air is not needed at all in this case. Results may prove his contentions to his own satisfaction; yet I confess that it appears to me that he would have a hard time to prove these different views from a scientific standpoint. Bees will nearly always winter out of doors with the cluster immediately over or back of the entrance, no matter where the latter is, provided it has been in that shape early enough in the fall. Whether the bees cluster in such a position to protect the entrance, or for ventilation, I am not sure; but I have proved by experiment that a good colony will winter, even if the entrance is shifted to the opposite side after wintering has started. As regards cellar wintering, the majority of those who thus winter are advocates of plenty of ventilation; and I suspect that many cellars get considerable air even when it is not actually provided for in a systematic way, thus making the beekeeper think that bees inside need no fresh air at all.

Beekkeeping Among the Rockies

WESLEY FOSTER, Boulder, Col.

Irrigation water is reported scarce in the Arkansas Valley; but sweet clover is abundant, and the bees wintered well, although grasshoppers are coming in fast. So far, grasshoppers are not much in evidence in Northern Colorado. A number of our Arkansas Valley beekeepers are replenishing their depleted colonies by shipping in from the South and Southeast.

* * *

THE HONEY MARKET.

The comb-honey market is practically bare. Prices range from \$3.25 to \$3.75 for clear white stock. While honey that is more or less granulated brings less, extracted honey in sixty-pound cases is worth about \$4.50 per can. There is a considerable supply of honey on hand, but in comparison with the total production it is relatively small.

* * *

BEHAVIOR OF BEES AROUND A ROBBER TENT.

Right after fruit and dandelion bloom closed it was difficult to work with bees. We had to use a tent 4 by 7 feet, without a top, and with mosquito-netting walls about 6 feet high. It is of just the right size to set over two hives so that two men can work in it together. It is amusing to see the robbers go around that tent looking for a place to get in. They will fly around two or three times in a regular swarm about two feet from the ground, and then rise in a body to the top of the tent, and some (not many) come over. They soon learn to attack the colonies after you have taken the tent away, so it is well to contract the entrances of the hives that you have looked at. After you have worked for several hours in a tent, the robbers will even attack the colonies ahead of where you are working; but by using caution we have not had any robbed out.

* * *

HONEY-CROP CONDITIONS.

Alfalfa began blooming in Oregon and Idaho the latter part of May. It is considerably earlier there on account of the low altitude. Throughout the inter-mountain West where the altitude is 4000 feet or more, alfalfa does not bloom before June, but from the first to the twentieth. A wet or a dry season affects this considerably. The wetter the season, the more luxuriant growth it makes, and the later it blooms. The price of hay is considerably lower at the present time than it has been for one or two years, and we are hoping this will have its effect on the farmers not

being in such a hurry to make the first cutting. However, I saw a mower being taken past our place the other day, so cutting the alfalfa is in the mind of some of the farmers any way. We are earnestly hoping for the time when nothing but the Grimm alfalfa will be sown. It blooms much more profusely than any other variety, and the great feature about it is that it begins blooming two weeks before it attains full growth.

June came in as a dry month. We had plenty of moisture early; but alfalfa that has not been irrigated begins to show the effects of drouth, and the sweet clover that does not have a supply of moisture at its roots is suffering.

Bees are reported in rather poor condition in the western slope. In Northern Colorado, especially around Denver, there has been less early swarming than last season; and, as compared with last year, there is much less honey in the hives June 1. In my own immediate vicinity I believe the colonies are stronger than at this time last year. White clover and what will bloom grows on the mesas and dry land are now furnishing about enough nectar for the bees to live on. However, I am giving each new swarm a comb of honey to make sure that they will not starve.

* * *

CONCERNING HIVE-RECORDS AND EFFICIENCY.

A beekeeper was telling me one day about his elaborate hive-record system. He had all his colonies marked so that he could tell upon coming into his apiary which were queenless, short of honey, weak, which had young queens, etc. It looked good, and was quite satisfactory, but there is another point to this. System gets in the way of efficiency if you get too much of it. Some of our largest beemen don't want a record system to last from one week's visit to the next. They want a clean slate every week. In other words, when a queenless colony is found, instead of marking it queenless, set it on top of another hive and be done with it. When a hive is weak, do the same or exchange places with a stronger one or give some hatching brood from another. Carry out this "do it now" principle and you will be surprised how little record system you will need in honey-producing apiaries. There is a difference, you know, between keeping bees and producing honey. If you are a honey-producer you do not have much time for record systems.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

TELEGRAM: (JUNE 17).

Crop conditions unchanged; worst ever.

BEES IN EIGHT-FRAME HIVES ENTER THE SUPERS QUICKLY.

Mr. J. L. Byer, in *American Bee Journal* for February, in commenting on my recent note in GLEANINGS relative to the size of entrances, upsets the theory of an eight-frame hive for comb honey, and at the same time upholds the idea that the larger the hive the sooner the bees build up in the spring. He says, "By force of circumstances I have almost all sizes in common use, from the eight-frame Langstroth to the ten and twelve frame Jumbo; and every spring, *without exception*, the bees in the eight-frame hives are the last to be ready for the supers." I believe this is the first time I have ever known a writer to advance so strong a plea for a large hive; and if it were not so absolutely at variance with my own experience I would surely give it more credence. Mr. Byer, no doubt, has some reason for making such an assertion, and under some conditions he may be correct; but as a rule I am sure the eight-frame hive will have bees in the supers before a ten or a twelve frame. I have the three sizes—not many of the eight-frame, about twenty of the twelve, and those in the twelve sizes are usually the last to enter the supers; but when they do get started, there is plenty of business, and plenty of bees to carry it on. Many of our best beekeepers and heaviest producers cut their hives to one story during the winter and spring breeding season to reduce the space that is to be heated by the bees to make breeding possible. Now, if it were not considered necessary to reduce the space during the breeding season the extra work would hardly be undertaken.

* * *

PROFITS IN BEEKEEPING.

Mr. Wesley Foster asks in the May 15th issue where I got my information crediting Colorado with 27,000 colonies of bees. If I am not mistaken I got it from some printed matter sent out by our State Association; and if it is not correct it was undoubtedly supposed to be, and was perhaps the best at hand at the time. I am glad Mr. Foster has made this correction. If the 1910 census should prove to be no more reliable in Colorado than in this State there

might easily be twice the number given by Mr. Foster. He also says, "But we have some of the best beekeepers to be found anywhere, and the homes of our beemen are a credit to the State;" to which I arise to remark, "*The same here.*" But do these homes represent apiculture or agriculture? I surmise the latter more than the former, for the Colorado honey sections follow the irrigated sections closely if I am correctly informed. That is true in certain portions of this State; but the greater portion of our honey comes from the part of the State that is considered at the present time to be valueless for agriculture. Perhaps 75 per cent of the beekeepers outside of the Imperial, San Joaquin, and Sacramento valleys, live in the cities, and many have very fine homes and all modern conveniences, while their apiaries are back in the foothills sometimes miles from a habitation. But did they make these homes as a result in beekeeping? In some cases they did, and in some they did not. There are those who have started in the business in a very small way who have worked up, have secured good homes, and have made a good living while others have invested heavily in the business at the start and have made a failure of it. One of the best-known producers told me recently that he wished he had invested in land years ago instead of bees, as then he would to-day be a very rich man. This is no doubt true; but it must be taken into consideration that he was figuring on the increase of land values and not altogether on what the land produced.

Bees are a good investment when properly cared for. The banker loans his money for 6 to 7 per cent on realty, and considers it a good investment. He can invest, say, \$2000 in the bee business, rent the bees out for half, and about one year out of every five he will get at least 30 per cent on his investment. Two years he will get 10 per cent, or an average of ten per cent for five years, allowing failures for two years of the five. Business and professional men care little for the business outside of returns on their investment, yet we find many of them owners of apiaries, which bespeaks volumes for the industry. I believe I have given conservative figures on the average.

I invested in bees in this State nine years ago. Two years, 1904 and 1913, I stand to lose five per cent on my investment. No other year have I made less than 20 per cent, and one year I made 125.

Conversations with Doolittle

At Borodino, New York.

HIVES AND DUMMIES FOR COMB HONEY.

"I have a few colonies, mostly in boxes of all sorts and sizes, and I wish to decide on some hive for future use."

"It is easier to decide on a hive for practical use in the production of comb honey to-day than it was forty odd years ago when I started in beekeeping. At that time very many of the hives most pushed on the beginner were much too complicated. They had slides, drawers, arrangements for catching moths, etc. Then many of the hives which were practical as to brood-nest and surplus were so large as to be cumbersome. The bulk and weight of any hive to be of practical value should be as small as may be. A hive that can not be handled easily by one man when it contains a colony of bees with from twenty-five to forty pounds of stores is, as a rule, to be shunned.

"The hive must not be expensive. Forty to fifty cents should purchase enough good lumber for body, cover, and bottom-board. There are few practical hives in use that do not embody the Langstroth principle as to frame construction. A simple box made to hold ten Langstroth frames with a super to match, suitable for holding the size of sections decided upon, is, to my mind, as good a hive as one costing three dollars.

"As to painting such a hive, I leave that matter to the desire of the individual. I do not paint. Looks count nothing toward a good yield of section honey. Dampness in early spring, in the interior of any hive, counts heavily against the maximum amount of bees for the early nectar flow from white clover; and a painted hive subjects its interior to a dampness that does not exist in an unpainted one. As to the durability, if a well-covered shade-board is used, as is necessary on any hive for the best results in section honey, the unpainted hive will last a lifetime.

"Besides the ten frames for the hive, it is well to make two or three *dummies* for each. Take a log to the sawmill and have inch-thick boards cut from it of the same width as the depth of your frame. Cut these boards the same length as the frame, and nail a top-bar to each. In this way one of these dummies can take the place of any frame at any time and in any place you may wish to use it. When the flow of nectar from white clover begins, and any queen does not keep the ten-frame comb-space occupied with brood, pollen, and honey, take out the unoccupied frames and insert a dummy in place of each frame taken out. This will throw the force of bees, and the

surplus nectar obtained, into the sections *right on the start*, and practically insure a good yield of section honey; while if the bees commenced to store this first nectar in the brood-chamber, little or nothing might be the result at the end of the season.

"Then there is another time these dummies can be used to good advantage in any locality like central New York, no matter how good the queen may be. Where the June and early July honey from white clover and basswood is nearly twice as valuable, pound for pound, as that gathered in the fall, and where there is a period of thirty-five to fifty days of entire dearth between basswood and fall flowers, this matter is of first importance. From past experience and observations I put the amount of honey needed to produce one pound of brood as two pounds; and as after several weighings I find that a well-filled L. frame contains two pounds of brood, therefore it is evident that such a frame of brood costs four pounds of honey. Five such frames of brood are all that is needed to keep any colony in good strength for fall and winter; therefore, all over this is an actual waste of our highest-priced honey where the eggs are laid after the bees coming therefrom emerge too late to work in the harvest from the white clover and basswood. As the harvest from basswood closes here about July 20, and as no eggs can give bees of value in any harvest sooner than thirty days from the depositing of the egg, it is easily seen that all eggs laid later than June 20, beyond those necessary for the successful existence of the colony, can be of no value to us. Hence, where the bees of their own accord do not restrict brood-rearing down to about five *full* frames, it is economy in white comb honey to use these dummies to compel them to do so. With black and hybrid bees these dummies can be made to pay from \$150 to \$200 each year where used in an apiary of one hundred colonies; but with a good strain of Italian bees (a strain which reduces brood-rearing as the flow of nectar increases) the use of these dummies for the purpose of repressing this out-of-season productiveness is not so apparent.

"As I have written in the past, the hive and strain of bees capable of putting the maximum number of bees on the stage of action in time to take advantage of the nectar flows, and as few at all other times as are needed to carry on the colony to a successful issue the next spring, are the ones to adopt."

General Correspondence

THE GOODS AND THE GAME

Why Some Producers Can Not Get a Reasonable Profit; a Better Package Needed

BY W. S. SHAFER

On page 620, Oct. 1, 1912, is an article by R. A. Nusbaum which is very good and right to the point, except that he did not go far enough. His four points of salesmanship are well taken. I speak after having had nearly twenty years of experience as a salesman in nearly every phase of the game; but I am a "Greener" in the handling of honey. However, I think I have made good when it comes to selling it. I speak of comb honey in particular.

The great big point, it seems to me, that Mr. Nusbaum omitted, is the goods. In the first place, a salesman *must believe in his goods* if he expects to make a success in selling. A half-hearted salesman is worse than none. Now, let us start with our honey as it is in the super, and follow it through the necessary preparation that is required to make it presentable for market (the manner in which we handle our honey). After it is taken from the super it is carefully graded, following as nearly as we can the picture grading-rules as given in the *Review*. Then each section is thoroughly cleaned, making the section wood as near its original color as we can. Then each is placed in an individual container, and four sections are packed in a folding box, and the box closed, making it dust and insect tight. It also makes a very handy and attractive package. After doing this we have goods that we can believe in—goods that we know are right and the best on the market, and we are fully justified in asking a price that is from five to eight cents per section above the store price for honey, and we get it; and for the last two years we have been unable to meet the demand for our comb honey.

We will use Mr. Nusbaum's own ammunition and try to shoot it harder. If the reader will notice, "grapenuts," "Meadow Gold butter," etc., are not handled in bulk nor placed in an open box so that flies and dust, which means germs, can accumulate; but, on the contrary, are put up in handy-sized packages which are attractive, and each package is sealed so that nothing can get to it. It is sanitary and clean—just what the modern housekeeper is looking for. Now, why should the producer of comb honey be behind in the method of putting up his goods for market? I spent a day in going from one broker to another

examining honey that was shipped to Omaha. In not a single case did I find honey that had been what we call cleaned. I also looked at honey in twenty different groceries, and in two places they had honey on display in a showcase, but their surplus was in shipping cases that had been opened and were under the counter. In the other places the honey was in the shipping cases on the counter, open to every thing. Now compare the average honey to the modern food articles in the average grocery.

Our own experience has been that, if we take good care in the preparation of our goods for market, we can get from five to eight cents more per section for it. To test out my plan I purchased two cases of honey from a broker, and prepared it as we do ours, and had no trouble in getting our regular price of twenty-five cents per section. It cost me fifteen cents per section.

Some will argue that we can not wholesale it and get the same proportionate price so as to make the extra labor and expense pay us. We will answer that by giving some of our sales last fall. One large concern heard that we had a new way of putting up comb honey and wanted to see it. After seeing it he wanted to buy the entire crop; but as we had worked up a retail business that took about all, we could let him have but 500 pounds, for which he paid us 82½ cts. per box of four sections, which equals \$4.95 per case—a pretty fair wholesale price. He sold it at \$1.00 per box of four sections.

We also believe in advertising. We have prepared a little folder telling about honey, which we distribute from house to house, also taking orders at the same time. That is, we did that last year. This year the orders have been coming in so fast that we shall not be able to fill them if they keep up. We also did some advertising through the press, and sent some personal letters, a copy of one of which is given herewith.

Dear Madam:—This is the season of the year when we are gathering Nature's harvest; and among her many gifts we find that pure honey is one of her triumphs. Its delicate aroma, its smooth, velvety taste and flavor all its own make it a dish that is fit to grace the table of the most fastidious.

The appearance of a box of our pure comb honey immediately appeals to your sense of cleanliness. It is packed strictly in accordance with our ideas, is absolutely clean in every respect, and is backed by our reputation for cleanliness. It is absolutely pure; has never been exposed to flies, dust, nor any unsanitary conditions. It is taken from the hive, placed in a container, then four of these containers are packed in a box and sealed, making it absolutely impervious to dust, flies, or any contamination.

"To touch a man's heart, tickle his palate." Try it with a supper of hot biscuit and honey.

In these ways we have been able to work up a sale for our honey that does not leave us one section of marketable honey at the end of the season.

Some will, perhaps, argue that it is impossible to prepare their product properly because of lack of time. It does take time, but it pays big dividends. We have about 150 colonies this year.

As an illustration of what good goods well put up for market and salesmanship will do we will say that three hours' work with a sample package of honey gave as a result: Net sales, 164 lbs. No sale less than four pounds or \$1.00, from that up to \$8.00 for 32 lbs.

We believe that the producer is as much at fault as the salesman. You can not get the top price for your honey if you give it the bottom preparation for market; but if you have goods prepared in modern style, coupled with modern salesmanship, there is absolutely no reason why the average honey-producer can not get from two to ten cents per pound increase for both his comb and extracted honey.

Bellevue, Neb.

PRODUCING WHAT THE PUBLIC DEMANDS

BY WALTER M. ADEMA

As some writers have said, it is hard to tell of one's failures, and easy to tell of success. I will try to tell of both. My bee-keeping experience started in 1906 when I got my first two colonies of my brother, who sold his bees—17 colonies in all—to go into other business for himself.

My first lesson, which was dearly paid for, was in not giving a stray swarm ventilation. I hived the bees on a hot close day the latter part of May. I left them in the shade of a tree in the forenoon so that they would mark their new location after the hive was opened. But to my sorrow the bees and combs were all one mass on the bottom-board when I opened the entrance. The heat of the bees had melted down combs and all.

At first I used the double-walled eight-frame chaff hive, of which I had about a dozen, which I had bought at a bargain.

In the spring of 1909 I started out with a new equipment, consisting of the Langstroth hive, three stories high, as I wished to run for extracted honey. One of the reasons for going into extracted honey was that I was unable to sell any comb honey locally. That is one thing upon which I wish to put emphasis—if one is producing for a local trade he must first find out what the locality demands. I find that a 10-lb.

friction-top pail is best suited to my needs, as ten pounds is as much as most families will buy at one time. At first I charged \$1.00 a pail. I soon felt that I ought to realize more for my honey, but I was afraid to change as I thought I would lose some of my customers. Last year, however, I charged \$1.25 a pail, and, strange to say, my sales increased, and I had to buy a large quantity with which to fill my orders.

I always make it a practice to insert an advertisement in our local newspaper each year after extracting, and find that it pays well. Just now I have a customer living a hundred miles away whom I got through our local paper. He had ordered over thirty pails so far this season. He is a factory man, and it seems no trouble at all for him to go among his fellow-workmen and get a club order for 60 pails. That is just the trade we want to encourage. It takes time and money to get customers like this, but once in your possession they are the best you have.

As to the financial part of beekeeping, I find that it pays better than any other farm crop.

I was fighting foul brood last season, and again this season. It's discouraging, it is true; but what calling in life has not its problems?

I winter my bees in a box large enough to take in ten colonies back to back. I pack them with straw, and cover the whole with tar paper. I find that they come out stronger in the spring than in double-walled hives.

I have added poultry along with the bees, and hope some time to devote all my time to bees and chickens.

Berlin, Mich., Dec. 11.

A STEAM-BOILER FOR ARTIFICIAL RIPENING OF HONEY

BY T. BOLTON

GLEANINGS for Dec. 15, 1912, p. 801, contains an interesting and instructive communication from Mr. Hopkins, of New Zealand, on the artificial ripening of honey—*atmospheric ripening* we can call it. For about twenty years I have been practicing artificial ripening. I have not depended upon atmospheric conditions, but upon a small steam-boiler and appliances devised by myself. By means of these I accomplish not only the ripening when such may be needed, and by that I mean the evaporation of any excess of water, and increasing the honey's specific gravity; but my main object is to clarify or refine the honey to make it amenable to rapid tanking, and to do

away with the old unscientific mess and bother of strainers and cloths.

The honey runs directly into the appliance from my extractor, which is driven by a small steam-engine. A $\frac{3}{8}$ -inch pipe takes steam into the jacket of the ripener, and on its way through it the honey is heated, refined automatically, separated from the scum that rises freely in the process. It is then pumped by the same power into the tanks. The next morning it is fit to draw off into 60-lb. cans, and will then keep uncandied after this process for two years or more; whereas if put into tanks in the ordinary way, cold and strained, it has to be drawn off within a few weeks or it will have to be dug and chopped out (certain varieties).

This once happened to me when I left a square tank of 5000 to 6000 lbs. of honey in midsummer newly filled. I went away for a few weeks, and came back to find that only the outer part of the honey was available by way of the tap, and the center was a huge pyramid, a mass of candy. For a week or more two boys had to get into the manhole of that tank, dig out the honey into dishes, and pass them to me to melt. I don't know how many chisels, trowels, and wooden paddles, improvised for the occasion, were bent or broken in the job. I might say that half of the tank was protruding outside into the sun's heat—my idea of the ripening process then being thus to cause a circulation in the tank through one side being hotter than the other.

After a few years I adopted steam heat in different experimental ways, till I have now a satisfactory appliance which saves both labor and time.

One reason why honey thus treated is not so ready to granulate is because such a large amount of presumably pollen grains and wax particles are removed, and cease to act in the bulk as centers or nuclei around which granulation gathers.

In one part of the apparatus the skimming is coarse and largely wax; in another finer, and largely pollen. The former is removed to the uncapper to be melted, the latter I am carefully preserving in 60-lb. cans for the next term of pollen drouth that comes along, and so seriously cripples our bees. I hope it will settle the trouble of feeding an artificial pollen, which hitherto we have sought for in vain.

There is always one drawback to any method of artificial ripening of honey depending on exposure to atmosphere for its effect. The exposure surface is large necessarily, and it is as large for the absorption of moisture as for heat and evaporation of it. Weather changes make it possi-

ble to lose one day what was gained the previous. This makes it a slower process still. But not only so, but the surface in its relation to the bulk or contents is large too, for the collection of dust; and over here we have dust storms that have great wall and roof penetrating power. Finally, the heat applied on the surface keeps the top layer warm, consequently lighter, and it stays on top. The colder layers that we want to rise in succession to be in turn warmed and dried are kept below. In short, circulation and air exposure are checked. But apply the warmth underneath, and what a difference in time taken and in the result!

Hamilton, Victoria, Australia.

HONEY NOT GETTING A FAIR SHOW IN THE STORES

BY L. RIEBEL

In my travels and in giving demonstrations with bees at fairs and at exhibitions of different kinds, it always annoys me to hear people call all kinds of liquid honey "strained honey." Many times, when there is a good display of extracted honey, people will call it "strained honey," when there is much difference between the two. Whenever I have a chance I make it a point to call at some of the largest groceries in the city where I happen to be and look up the honey proposition, I frequently have an experience like this:

In talking to one of the head clerks or the proprietor I inquire whether they have any honey, and learn that they have section honey and strained honey. I state that I should like to look at it, and almost invariably find some extracted honey gotten up in good shape. I then explain the difference between strained and extracted honey; but if a customer comes in and asks for honey while I am still there, the clerk or proprietor to whom I have been talking says that they have *strained* honey.

I think that the merchant himself is largely to blame for not informing himself on the different kinds of honey just as he would on other goods.

CARELESSNESS IN DISPLAYING HONEY.

The independent and careless ways of merchants in putting comb and extracted honey before their customers is to be deplored. In a large store in a town of 30,000 I once saw eight single-tier cases of comb honey—fairly nice-looking honey—in $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{7}{8}$ sections, piled up, four cases on top of each other, and the lower case on the floor, with the glass broken. Some one had shoved the toe of his shoe through

the case. You could see the prints on the section of this same case. Another case showed marks left by the broom as it had swept along the floor. At one side there was a basket of potatoes; on the other side, half a barrel of pickled tripe. Both upper-tier cases were open, and about half full of sections, some of which were lying flat, some edgewise, some crosswise, more like potatoes in a basket than honey. Many of the sections showed thumb and finger marks, and were badly stained. This, mind you, was what was considered to be a "swell" grocery—in fact, the best store of the kind that I visited that season.

Then, again, I have stepped into a grocery where the farmers were bringing in comb honey in supers. The merchant would take it and set it on the counter just as they left it. It was evident that no separators or starters had been used, and sometimes the honey was in old sections, which were then second-hand. The honey bulged in all kinds of shapes, and such a mess as the clerks and merchants would make in getting it out! I place the blame on the merchant for accepting honey in that shape. Is it any wonder that honey has to take a back seat, and does not move off in the local market as do other goods?

There is one thing I can not understand: Why merchants who have made grocery-keeping a business, and take pride in keeping other goods neat and attractive, should give honey such a black eye. They would not dare to treat butter or other commodities that way or they would soon lose their butter trade.

It is surprising to know how little people in general know about the bee and the way in which honey is made. What a field there is to labor in! I am doing what I can to educate people as I have opportunity, and most of them seem to appreciate it. I think this matter should be brought before the merchants in some way, either through the columns of the newspaper or through little pamphlets which will interest them until they will take, at least the same interest in honey that they do in other lines of goods.

Chariton, Iowa.

ADVERTISING UNTIL THE CUSTOMERS COME TO THE HOUSE

BY GEO. SHIBER

On p. 632, Oct. 1, 1912, I find a very readable article by Mr. C. W. Powell on organization by beekeepers for the purpose of better disposing of honey. I have no doubt that organization is a good thing;

but I am sorry to see him bolster up his argument by saying, "A rocking-chair for which you pay the dealer \$5.00 costs him \$1.50;" and "carpets selling at retail for fifty per cent profit." That would be too far "up in the air," for the Eastern States at least.

Now let us consider for a moment the question of the best way of disposing of a crop of honey. Mine is all extracted. There are two or three things that are very necessary for selling direct to the consumer. I am not going to say any thing about putting it up in 60-lb. cans and bringing to a honey-buyer. That's easy, but it doesn't bring as much cash.

The first important thing is to have your product fancy, all sealed.

Second, put it up in packages of about ten or twelve pounds, and some sixty-pound cans. Draw it off in these packages, just as fast as you throw it from the combs. Have the honey-tank emptied every night. The sooner you can seal up honey air-tight after the combs are taken from the bees, the better. This is one thing I feel that I *know* about beekeeping.

The next thing, let people know you have it for sale. The cheapest way I have found is a reading notice in the town paper like this, run very week until the crop is sold:

HONEY.—I could fill this paper with letters and words of praise I have received in regard to its quality. I have it in gallon tin cans and five-gallon tin cans.

SHIBER'S APIARY.

Canvassing? I never canvassed a minute in my life—people come after it.

Perhaps you may think a little may be sold this way, but not a crop that goes up into the tons. Well, year before last was a very poor one, and nearly 4000 lbs. was sold before Thanksgiving. Last year, with a crop of 8000 lbs., it was nearly half sold by Oct. 1. We sell gallon cans at \$1.45; two-quart glass jars at 85 cts.; one-quart glass jars at 45 cts. At those prices it is a cheap food. Why, last year one man bought four one-gallon cans, and after New Year's day he was asking for another can, but it was gone.

MERE PUBLICITY OF NO AVAIL.

I want to say that the reason why it is hard to sell honey from one's home direct to the consumer is because very few people know he has it for sale. Oh, yes! I know the local apiarist has the reputation of being a beeman, and whenever he gets into a crowd or goes into a store the hangers-on usually try to start some bee-yarn about a bee-tree that "Abe Baldwin cut once," and how the speaker "didn't get stung once," etc.; or to have the reputation of "going out to hive a swarm of bees without any

ADVERTISING HONEY WITHOUT EXPENSE

BY JAY SMITH

Beekeepers as a rule do not realize what an advantage they have in the way of securing free advertisement—not only free, but, if properly managed, one can get pay for advertising his own business. We beekeepers study the mysteries of the bees, and discuss them among ourselves through the medium of the bee journals until to us they are commonplace. The rank and file of the honey-consumers never get to know of the marvelous things of interest concerning the bee and its works. It is “up to us” to

A similar picture of Jay Smith has appeared in hundreds of magazines all over the country.

give them, through the newspapers and magazines, live, interesting sketches of the bee and honey industry. They like any thing unique, original, and interesting to the public. Of course a person must not give the articles the appearance of advertising or it will “queer the game.” It is not necessary to say that you have honey or bees to sell. If you have bees they will know that you have honey. I have frequently noticed the surprise of people when I tell them that I produced a ton of honey. The word “ton” seems much bigger when applied to honey than does 2000 pounds. So does “half a ton” or a “quarter ton.” It probably seems big to them because they were familiar with it only in spoonful lots when colds were prevalent.

Then, again, the public can not get away from the belief that the principal business of the bee is to sting—that the sting is something awful, and that, if you go near a hive of bees, you are taking your life in your hands. Some of the common stunts that are pulled off among the beekeepers would amaze the public.

One of the most successful things I ever did in the way of advertising was by the use of the accompanying cut. If I could call for a show of hands as to how many readers of GLEANINGS have seen this picture thousands of them would respond. I made this photo last summer more for the fun of the thing than for any thing else. I made several negatives, and sold one of them to Underwood & Underwood. They must have made a good thing out of it, for it is still running in papers and magazines all over the world. Scarcely a day goes by but some one brings to me a paper in which he has discovered my picture. One saw it in *Harper's Weekly*; another in the *Chicago American*; another in the *St. Louis Democrat*, and another in a supplement to a Sunday paper. I have heard of it from Los Angeles, Cal. From Texas a paper came from a relative with the bee picture in. The president of our university attended the inauguration of President Wilson, and while there he mailed me a New York paper with my bee whiskers in. (Underwood & Underwood give it the dignified name of “Bee Beard.”) From far-away Idaho comes word from our friend Geo. W. York that he saw it in a paper. I mention this to show how the public is interested in any thing unique in the bee line.

I do not know how much good this has done me in the way of selling honey; but I do know that I have sold more than twice as much honey this year as in any previous year.

Vincennes, Ind.

SELLING HONEY BY THE CARLOAD IN ARIZONA

A Brief Mention of Some of the Men who do it

BY WM. LOSSING

One of my customers, Mr. Peter H. Benson, of Palo Verde, has sold me two carloads each year for the last two years. He is a farmer making the bees a side issue (a rather good-sized issue). His equipment consists of 500 colonies divided into three apiaries. At each apiary there is installed a six-frame automatic power extractor and a $1\frac{3}{4}$ -power engine which is conveyed from one yard to another. He also has a pump,

Loading the largest car of honey ever shipped out of Arizona. Fairground siding, Phoenix, Oct. 4, 1912.

steam honey-knives, Hatch wax-press, and settling-tank having about 200 gallons capacity. The buildings consist of up-to-date honey-houses, finest of sheds, and a galvanized warehouse 20 x 30.

The hives deserve special mention. The Hoffman frames have long molded top-bars, and are wired and fitted with full sheets of foundation. The hives are of the ten-frame size, and are made of redwood. There are 500 wire queen-excluders and 100 bee-escapes. At each yard is a Daisy wheelbarrow, and some smokers and veils. The bees are the result of much care and judgment, which is plainly shown by the uniform markings of the Italian bees.

Mr. Benson is practically a new man in apiculture, and a fair sample of many instances near Phoenix where new beemen have sprung up, as it were, and budded, bloomed, and bore fruit in one night.

The illustration shows the largest car of honey ever shipped out of Arizona. It was loaded at the fairground siding, Phoenix, Oct. 4, 1912, and was one of 16 cars shipped by the undersigned, an independent shipper. This amount is about half of the honey produced in the vicinity of Phoenix, including Buckeye and Palo Verde, Ariz. The car is the product of beginners, one of which, whose check amounted to over \$1200, is J. J. Myers, of Phoenix, who never sold

a pound of honey before, last year being his first. In the picture four of his teams are shown, and Mr. Myers himself is sitting in the foremost wagon, as dignified to all appearance as a full-fledged apiarist.

John H. Bennett, another new shipper, is managing about 500 colonies. His check was not quite as large, he having retailed a great deal of his honey in the city. His outfit seems to be about as near up-to-date as any of them. He has a migratory honey-house equipped with a four-frame automatic extractor, gasoline-engine, and other implements necessary for carrying on his successful operations. Much is predicted of John.

Among the other new beemen of the past few years I wish to mention a few of the principal ones. Albert J. Ross, of Buckeye, is cutting a wide swath in the line of apiculture. Two years ago he bought 600 colonies on time. That fall he paid from his honey money about half of his indebtedness. Last fall he sold enough honey (nearly two carloads) to put him out of debt and place him in good running order for the next year, such as buying a small tract of land, building a new house, and taking unto himself a helpmate. The writer bespeaks great success for Albert.

One James H. Tracy, Buckeye, who has been in the bee business for several years,

has demonstrated beyond a doubt the profits that can be made in the bee business in Arizona. The last three years all his honey put together would total about nine carloads. These carloads of honey range in cash from \$1600 to \$3000 per car, regulated somewhat by the amount and price in the car. Mr. Tracy has a nice little home, out of debt, 700 or 800 colonies of bees, a good horse and buggy, and money in the bank. The one improvement that I would suggest would be a nice wife; then Jim would surely be on the road to happiness and prosperity.

If this article does not find its way to the waste-basket I shall be pleased to finish the report, as we have many beginners who are worthy of mentioning, a few of whom I will simply name for the present: Wm. Doner, Walter Dickerson, Levi J. Holtzworth, Mrs. L. D. Smith, Mrs. May G. Lovett.

Phoenix, Ariz.

HONEY-SELLING VIEWED FROM A STORE-KEEPER'S STANDPOINT

Wrapping Each Section in Transparent Paper Tied with a Silk Thread, and Selling for a Fancy Price

BY C. B. PALMER

Shall we improve the style and appearance of the section of honey, and keep pace with all other packages of merchandise now handled in the grocery or general merchandise store, and receive a better price for our improved package? Or shall we continue to place our sections on the counter in the same old way we have done for years, and then wonder why our honey brings no better price than it did last year or the year before, or, in fact, than it did fifteen years ago? and also why there is not an increasing demand? I doubt if there is a food in our store, the style of package of which has not been improved on in the past few years. We must cater to the demand.

Back in the seventies, when as a boy I was drawing wood into old Kalamazoo, father would sometimes say, "Take a grain-sack along and go to the bakery and bring a dollar's worth of little round butter-crackers, always so fresh and crisp."

Go to your store now and ask for a dollar's worth of crackers. You will be lucky if you get five packages, and on one end of each package will be marked in very small type, "This package contains twenty-nine ounces of crackers." But see the elegant, bright, pretty package. Some one has seen fit to cater to the demand of the trade, and you can scarcely find a family to-day

that does not keep crackers constantly in the house.

A glance over the shelves in my store tells me that the old method of handling honey must go. The method is so crude and so antiquated that the food commission had to compel us by law to carry our honey in glass show-cases or other suitable covering. Sections of honey are much easier to enclose than many other packages of foods, especially dried fruits or foods that contain oils, or any food that the moth miller can reach.

I can count more than fifty different packages of goods put up in the most attractive forms possible. These were all handled in bulk only a few years ago. But should I order a case of honey it would come in the same old mussy leaking condition. No wonder that merchants do not try to create a demand for this class of goods. It is up to the producer to increase the demand.

One of the most attractive packages I have is a three-pound rice. I have this same rice in bulk in a dish on the counter, marked five cents a pound, but no one wants it. It does not attract the buyer's attention. It is the old-style method of showing goods, and customers are looking for something new. Consequently they take the three-pound package at twenty-five cents, and are pleased. The producer of the beautiful gilt package has increased the selling value of the package, and at the same time increased his own profits as well as mine.

The large producer of honey has no trouble in finding a market, as he has made a study of the demand and knows how to supply it. It is the man with only a few pounds or a few hundred pounds who becomes discouraged and soon drops out for lack of a market for his few pounds of surplus. When I found myself in this position I began to look around for a market. I found every store supplied with honey, from honey one day old (the merchant had lost a stand from disease, and he was pressing the honey out of old filthy combs into glass fruit-jars), to honey so old that "whiskers" were growing on the sides of the case. Some of the honey looked like some of my own, especially that with the "whiskers;" but all, good or bad, was in $4\frac{1}{4} \times 4\frac{1}{4}$ sections.

I decided that, in order to sell my honey and make a demand for it, I must first change the shape of the package so that the customer would not be looking at the same old mussy, grimy, dusty section, and I decided to overhaul all my supers and produce nothing but 4×5 sections. Then I would see how nice I could put them up

for the trade. All the time my thoughts were to cater to the trade, leaving the price to take care of itself, if I created the demand. As a result, for the past few seasons our honey has been sold up a year in advance, and for three years we have not had honey to retail from our own store.

SHIPPING SMALL AMOUNTS OF COMB HONEY,
FROM A FEW SECTIONS TO A FEW
THOUSANDS.

I use a common candy-pail, which is charged up to the customer. He can always sell the empty pail or return it for credit. The pails can be procured in any size. I use one 11 inches deep and $12\frac{3}{4}$ inches across the top, inside measurement. It holds thirteen 4 x 5 sections in the bottom layer and fifteen in the top, twenty-eight in all.

To pack the pails, twist some *clean white* paper into ropes and crowd between the inside of the pail and the sections. Care must be taken not to crowd the face of any section. However, no one but a careless packer can do this, as the wood comes nearest to the pail at all points. Crumple more paper and fill the top of the pail and place

Wooden candy-pail for shipping comb honey. A shipping case that is proof against honey breakage.

the cover on. There are two small wires that bend over the cover. Put a common nail in the loop, twist the wires together, and the pail is sealed better than any nails could do it. The pails are all painted white,

and marked on the top "Comb honey. With Care." Braided cornhusks would be even better than paper, and would add to the appearance.

The sections should be honest, even weight and color. No section should weigh less than $13\frac{1}{2}$ ounces. (The first two seasons I shipped nothing under $14\frac{1}{2}$ ounces.) They must be perfect, and No. 1 in formation and capping. Then quote by the section and seek in a city for a customer who can use all you produce. Employ all your spare time improving the appearance of the section so it will sell, and orders will be repeated. I would not care for a customer who did not repeat. You are the producer. You make the package attractive, and the price will take care of itself. If a customer does not repeat, it is your fault and not his. He has to have the honey to sell, and you must create the demand for *your* honey.

I have been in my store for thirty years, and I know the kind of goods that sell. When a lady sees a new-style package of food, and is shown that the package is fly and dirt proof, she is always interested and expects me to talk up the goods. She is attracted as much by the package as by the contents. Nearly always I make the sale, and the next day I have calls from her neighbors for the same article.

Each section should be wrapped in transparent paper, and tied with a strand of bright-colored silk. I think the coming season will see all my sections tied with a ribbon similar to "baby" ribbon. Our honey crops are sold a year in advance. For three winters we have not had honey to retail at home, and to-day we have none for our own use.

We have been shipping in these pails for about seven seasons, and have yet to get the first report of contents received in bad order. We have taken particular pains to ask express agents at destinations to examine shipments, and all have reported best of condition. No pail has ever been returned to us with a stain or mark of a broken section. In fact, one can safely guarantee that honey packed in this way will arrive in a satisfactory condition. The secret is in the shape of the package, since one can not be set flat down, but always strikes the edge and has a rolling motion.

We have customers in several towns and cities who sell from a few hundred to a thousand sections to whom we have had to return their extra orders unfilled. Frequently strangers come into the store and make the remark, "Oh! this is where the honey comes from, tied with a silk thread." So we see that the smallest detail, the silk

Kirkpatrick's honey-wagon.

thread, is noticed, and serves as a trade-mark. An old customer called, and said she had come for a pail of our honey, and asked us to ship it to Lincoln for her. I told her that this would be impossible, as a dealer there had bought all our crop; and as we were shipping about 600 lbs. that week she could get the honey of them. She did not think that was exactly fair in us, but we wrote our customer to see her at once and sell to her.

Be sure to protect your customer, and be very careful not to compete with him. I could have made fifty cents more on the pail by selling to that lady, but I might have lost my customer. We positively refuse to sell at retail to any one who lives in a town where our honey is on the market, although we have many chances to do so.

Pradshaw, Neb.

SELLING HONEY DIRECT TO THE CONSUMER

BY GEORGE H. KIRKPATRICK

Beekeepers who have the time and talent may dispose of a quantity of honey at retail price. By a thorough house-to-house canvass in the neighborhood or county I have sold many tons of extracted honey to farm-

ers, lumbermen, and wood-choppers. In selling honey in the homes we must abide by the golden rule and always do unto others as we would they should do unto us.

When approaching a new customer ask him for a few moments of his time, and then in a few words give an outline of the proposition. At the same time remove the top from a pail of honey, and ask the prospective customer or his children to sample the honey. With book and pencil in hand ask the gentleman for his name and address; and while writing it inquire how many pails of honey he wishes. He will be quite sure to take a pail; but if he should not it will do no harm to have his name and address.

Offer for sale only the best honey, and ask a fair price for it, which should be 5 cts. per lb. above the wholesale price. The honey should be put up in ten-pound friction-top pails, and neatly labeled. Make the same price to all customers, and request the retail grocers to whom you furnish honey to sell to their customers at your retail price.

One of the most important parts of the equipment is a special vehicle, neatly painted and lettered. Such a rig will bring many a customer who would otherwise be missed. The illustration shows my vehicle. It is painted white, and lettered in black. It has

a carrying capacity of 500 lbs., or 50 ten-pound pails. Fifty-one ten-pound pails are also shown ready to load in. The same body can be put on a sleigh for use in winter. I also have another wagon having a carrying capacity of 75 ten-pound pails. Both rigs proved comfortable to ride in, and a great help in selling honey.

Rapid City, Mich.

WHY THE DARK COMB HONEY SOLD SLOWLY

BY N. B. JOHNSTON

Without being able to give the dates when they were published, the writer recalls several short articles emanating from the editor, somewhat in the nature of remonstrances against the tendency of apiarists to produce and to offer for sale an excessive quantity of extracted honey at the expense of the quantity of comb honey produced. I would make a few remarks on that position of the editor, subject to such reply or criticism as may seem proper.

I wish to state in the first place that, although this will be the eighth season of my experience as a beekeeper, I still feel myself a novice at the business, as I see so much about it which I must learn before I can consider myself or would be considered by others as an expert. During all this time I have confined my operations to the production of comb honey. Although I have had an extractor during the past two years, I used it to a very limited extent last year.

My advance in a knowledge of the business has been slow, and my production consequently small. For several years after starting I was able to dispose of my honey without much trouble; but last year my increase had attained a total of twenty-four colonies, two of which produced nothing; and three others, being utilized in carrying out Doolittle's method for swarm prevention, left me nineteen only as honey-producers, from which I obtained about 2000 well-filled sections, a large proportion of which was, as it appeared to me, as pretty honey as could be made in this region, though I have never seen (what I read so much of in GLEANINGS) any of the handsome honey made in the North, so I can make no comparison between it and the product of the bees in the South, samples of which I sent at Christmas, in twelve-section shipping cases, to friends in North Carolina, Virginia, Tennessee, and Pennsylvania, all of whom, whether to flatter me or not I can not tell, pronounced it "delicious." This,

after making some small sales on the home market, left me with something over 1700 sections unsold, which I shipped on consignment to a large produce house in one of the largest cities in the country. I was advised that it all arrived in good order, no complaint being made on any score (though I especially invited criticism for my own information), except to say that, owing to color, it was not so acceptable to the trade as was the white honey from California; but knowing that every thing offered in the market, in other lines than honey, is not always, and all the time, "first class, A No. 1," I supposed that a market would be found for this shipment, though not expecting such prices for it as could be obtained for the more popular kinds.

But in this I have been much disappointed, being advised within the last few days that still one-fourth of the shipment remains unsold. This unsold portion is doubtless the darkest, which you say the people up your way will not buy, notwithstanding the positive claims of your Texas correspondent of last year for its superiority. We can not control the operations of the bees in this respect, and must take what they give us.

In contrast with this I shipped a small quantity of the same honey, which had been extracted, to a dealer in another direction, and received returns for it within a few days after its arrival at destination; and the problem which confronts me is how I shall shape my operations for the coming season. I have a full outfit for comb-honey production, and also an extractor. I now have 31 strong colonies. So far as I am concerned, beekeeping is only a side line as a means of occupation during a protracted period of idleness in my regular business. I secure more entertainment and occupation in handling the apiary for comb honey than for extracted; and I like that branch of the business best; but if I can not sell the product, how can I make the business even self-sustaining, to say nothing of its being profitable?

Greenville, Miss., March 25.

[We may be wrong; but we should say that a local market should be built up to take care of the darker grades of comb honey. "Snowy-white" sections usually sell the quickest, and on this account dark comb honey should not have to compete with the white. There are many localities where the darker honey is better known (and better liked), and as a rule it is best to seek such a market rather than one where the demand is largely for the white.—ED.]

HOW ARRANGEMENTS ARE BEING MADE FOR THE HANDLING OF HONEY

BY E. G. WARD

The pictures shown herewith illustrate a new departure in the history of the disposal of honey produced in New Zealand. It has been well known among beekeepers that the production has been steadily increasing for a number of years, and that each year sees an increase of those engaged in the industry. The season of 1912-'13 has been an exceptionally good one in most parts of the dominion, and in Canterbury in particular. These conditions have all tended to bring matters to a head; and the result is that the National Federated Beekeepers' Association of New Zealand has now completed arrangements for the first shipment of first-class honey under government grading rules. The shipment consists of 11 tons, all sent by two producers only, and a similar quantity will be dispatched next month, and subsequent shipments as producers get better acquainted with the scheme. The first shipment will leave early in May; and as the quality is so high there is no doubt of

E. G. Ward, Christchurch, N. Z., Secretary of the National Federated Beekeepers' Association.

good prices being obtained. The fact of having the government grading mark will be a guarantee of quality; and as it goes under the supervision of the Federation, beekeepers need have no fear but that their interests are fully safeguarded.

Honey exhibit by the Canterbury Beekeepers' Association at the chrysanthemum show, Christchurch, N. Z., April 7, 8.

Mr. C. A. Jacobsen, President of the National Federated Beekeepers Association, and part of the first shipment of honey. Each case contains 100 lbs. Mr. Jacobsen has conducted the negotiations with the firm of Montgomery & Co. for the Federation.

Inquiries are coming in daily to the secretary, and the success of the scheme seems to be assured. It is necessary that any one sending through this channel should endeavor by every means in his power to produce nothing but the best honey, and handle it in the cleanest manner. No unripe honey will be sent; and it must be in granulated form. The cases should be new and clean, bound with iron, and branded on one end with the initials only of the producer. Tins must be new and clean, and contain 56 lbs. net each, and packed two in a case. A sample must be sent first to the secretary for approval, and on approval the place to consign to will be mailed. It will then be graded by a government expert, and stamped, and then shipped as soon as convenient. Arrangements can be made for a cash advance when ready to ship, and centers other than Christchurch will be established when sufficient inducement offers.

Christchurch, N. Z.

Case of Honey graded and sealed with the N. F. B. Ass'n certificate attached.

SELLING HONEY TO RETAIL GROCERS

BY H. W. DOERR

Taking for granted that one has the bees, hives, and the necessary equipment, the next important thing is the honey itself. After I have the honey, the next step to take is to find out its kind and quality. In fact, I watch this point from the time the bees begin to store a surplus until the honey-flow ceases. I also keep tab on the honey-crop reports as given in the bee journals, and study the market quotations of the newspapers with the view of determining what honey of the same quality as mine would cost if shipped in from some other locality, and also what my honey would net me by shipping it to some other market.

Having fixed these two points clearly in my mind I proceed to fix my price by striking a mean between the import and export prices. That is, I make my price somewhat higher than the export price, and somewhat lower than the import price, because experience has taught me that it is safe, and good business policy, to do so. Right here let me say that it is of the utmost importance to have the price set on your honey before you offer it for sale. Otherwise the dealer will be slow in buying, and he will pay you just as small a price as he dares to give.

After the question of price is settled, and I have decided to put my honey on the market, the next thing that I do is to give some attention to my own personal appearance. This does not mean that I put on the best clothes in my possession, nor any display of style; but I do shave, and lay aside my daily working clothes for others which are neat and clean. Then I make a tour, interviewing the different grocers of my home town. When I step into a store where the owner is not known to me I inquire for the proprietor. Having found him, I usually ask him if he handles any honey. His answer generally is that he has none on hand at the present time. Then I ask what would be the chance of selling him a case of honey to be delivered in a week or so, naming my price, and stipulating that I will take a part of the pay in trade. This usually closes the deal for a case or more.

If I have had a good look around the store, and find no honey in sight before I meet the proprietor, then I sometimes ask him point blank if he has any honey to sell, to which he usually says he has not. Then, of course, I ask what would be the chance of selling him some honey, so that he will have some to sell. If he is a free talker I

Christchurch offices of the shipping firm of Montgomery & Co., who handle the honey for the N. F. B. Association of New Zealand.

let him ask me about the kind, quality, condition, and price, which I promptly tell him; but if he is somewhat reticent I do the most of the talking, explaining the kind, quality, condition, price, and terms of sale. In this way I seldom fail to land an order for future delivery.

I always sell on future delivery, for several reasons. First, if I have the honey with me for immediate delivery I never can make as good a sale as I can on future delivery. Second, if I have the honey with me for immediate delivery, and I fail to make a sale, I take too much of a risk getting it damaged by having to haul it home again.

I remember going into a store one time where the proprietor was not known to me, and every one connected with the store was busy. I had been in the store a few minutes when a friend and acquaintance came in and began to jolly me by wanting to know what I was doing in that part of town. I told that my business that day was selling honey.

"Oh! you keep bees, do you?" he said.

I told him I did. Then he began to ask questions about bees and honey. I answered his questions, and explained my way of producing honey. Before I got through, five or six others had come in and had joined in the conversation. Finally the proprietor became curious to know what it was all about; so he came up and listened until he found who the bee and honey man was. Then he asked me if I had any honey to sell. Certainly I had. Would I bring him

a case next time I came to town? Yes, I would. Thus I got his order without telling him the object of my visit.

When I go into a store where I am acquainted with the proprietor, and it is at the opening of the season, and I have sold him honey before, I simply ask him, "How is the honey business?" He usually asks about the kind, quality, and price, which I tell him, and I usually get his order. I never try to persuade a dealer to take a case of honey against his will or judgment.

My honey is all stored in one-pound sec-

tion boxes, and I market in glass-front single-tier shipping cases. These cases I leave with the dealer until he has all the honey sold out, when I take them back and refill them.

In preparing my honey for market I scrape the gum or propolis off as well as possible, and grade it carefully according to weight, color, and quality. I also make it a point to deliver at the appointed time.

My 1912 crop of honey was sold practically without any solicitations. In fact, a large part of the orders came voluntarily by telephone. And this reminds me how I have taken orders by telephone in the past. If I decide to sell honey by telephone I call up a dealer who knows what I have; and when I get him on the line I say to him, "This is Doerr, the honey-man. How about bringing you a case of honey to-day?"

If he is out of honey, or his stock is low, he will say, "Bring me in a case." If he is not quite ready for it he will say so, and name a time for delivery of the honey.

I find it a great advantage in making a sale of honey to take out part of the pay in trade, as already stated. I can make sales based on that sort of terms when otherwise I could not sell at all. If a man asks me to take out all my pay in trade I decline to sell, saying that he does not handle every thing I need, and must have cash to get them at other places. This statement almost always wins him, and I get his order according to my own terms.

I also make it a point to advise a dealer how best to take care of the honey and how

Bringing in a shipment of 11 tons from the railroad siding, to be graded. The cases are opened ready for grading, and the government grader (in center), Mr. L. Bowman, ready for work.

to display to the best advantage for the purpose of bringing it to the notice of a prospective purchaser.

Most dealers like to talk bees to some extent; but their conversation is of an interrogative nature. Some want to know what the king bee does, and what position he holds in the society of beedom. I tell them that the head of a colony or swarm of bees is not a male but a female, and is known as the queen, and that in reality there is no such thing as a king bee. Moreover, the queen ordinarily is the mother of every bee in the hive of a well-regulated bee family, and is the only bee in the hive capable of living more than a year, and that the well-being and prosperity of a colony of bees depends upon the prolificness and health of the queen.

On the other hand, there are some who want to know if those big fat fellows which one sees hanging about the entrance of a hive on warm summer days are king bees, and then I explain about the drones. Sometimes I run across a fellow who has the artificial-comb-honey bogie in his head, and he will go to considerable length trying to

show that there is such a thing as artificial comb honey. I call his attention to the fact that The A. I. Root Co. has been offering one thousand dollars for a pound of artificial comb honey that can not be detected from natural comb honey, and that this offer has been standing over twenty years, and so far has had no takers; but if he has the goods, or can get them, the money is worth the effort. So far no one has offered to produce the required pound of artificial comb honey.

I also find it advantageous to study the different temperaments of the various dealers. For instance, if I meet a man who is lively and full of fun I jolly him or tell him a funny story. On the other hand, if I meet a slow-going steady man, I don't rush him, but give him all the time he wants, and make only such remarks as are necessary for the intelligent transaction of business.

Thus I keep up the interest in my stock in trade, and the sales continue to increase, until to-day the demand is greater than the supply.

Beardstown, Ill., Feb. 24.

SELLING HONEY FROM HOUSE TO HOUSE

BY A. L. BEAL

To my mind the most delightful thing about the whole bee business is to sit and watch the bees work when there is a good honey-flow. For tired nerves and a fagged-out brain there is nothing better. It is an inspiration to any one. A few days of watching the bees will put even a person of poor health in a good condition for "marketing honey," which is the next most delightful thing in bee work, and almost as healthful as watching the bees. I have never found more than one discouraging feature in marketing the honey; and that is, it is so soon sold, and so many people are yet wanting honey. The oddest thing about it is, the more you sell, the more people will be wanting it when you have sold out.

I believe that I know exactly how the ordinary beekeeper can market his honey, and at a fair price. I have had several years of experience in selling produce direct to the consumer, and I never represent what I have to sell as having qualities which it does not have. I always try to avoid exorbitant prices, and to be strictly conscientious in every thing, and so when I commenced selling honey two years ago I had no trouble at all.

Get some Mason glass fruit-cans, pint and quart size. Fill them nearly full of comb honey, and pour in liquid honey until the pint weighs $1\frac{1}{4}$ lbs., and the quart $2\frac{1}{2}$ lbs. Be sure to have the cans full. A little practice will enable you to know just the proportions of comb and liquid honey to put in so the can may be full and of the proper weight. Then take a few more cans of each size, and fill them with liquid honey. They should contain by weight, pints, $1\frac{1}{2}$ lb.; quarts, 3 lbs. If you have a few pound sections that weigh 12 or 14 oz., get some of those too.

Load all these in your rig and start for town. Any town will do, but the bigger the better. Stop at the first house, and take as large a can of the bulk comb honey as you have on the wagon. Holding up your can, say, "Good morning, Mrs. A. Are you a lover of good honey—honey that is honey—real old-fashioned bee honey?"

Keep holding up the can, and change its position and keep talking. But do not talk all day. Let her ask the price. Then you can tell her it is 20 cts. per lb., and $2\frac{1}{2}$ lbs. in a can. Be sure to say it that way. If you have ever been an agent you have learned the great power in certain combinations of words. Never use the term "half

a dollar." Well, it may be that Mrs. A is not fond of honey—doesn't know how good it is, and doesn't wish to buy. Then leave as politely as you can. Do not urge her to buy. Before your next visit to town she may have heard how good it is, and be watching for you.

Mrs. B is quite fond of honey, but has only 25 cts. about the house. Sell her a small can. Get your can back or an empty one in its place.

Mrs. C doesn't like comb at all, but would be "awfully glad" to get some "strained" honey. Sell her two cans—quarts, of course—and take the pint on to Mrs. D, who is short on change.

Mrs. E always gets it in "these little boxes." Sell her a light weight for 20 cts.; and so on down the line to X Y Z if your honey holds out.

Tell them all you will be back, and don't forget to go back, for most of them will eat all the honey long before the appointed day.

Westfield, Ind.

ADVERTISING PAYS

A Producer who has Spent Several Thousand Dollars in the Past Four Years in Advertising

BY R. M. SPENCER

What would it mean to all the beekeepers of the United States if the price of their honey should be raised 1 ct. per lb.? It would mean thousands of dollars, and, in many cases, put the bee business on a more profitable basis. Many will say the supply and demand regulate the price. This no doubt is true; but it does not mean that we can not increase the demand. This can be done by producing a first-class article and creating a demand by advertising.

To obtain these higher prices, all apiarists should endeavor to produce a better and riper grade of honey that has the quality behind it to bring the repeated orders from their customers.

All honey of the best quality and grades should be advertised under a trademark, thereby giving it a name for the customer to remember and order by. As long as the quality is held up, the business would about double each year.

I have spent several thousand dollars in advertising honey in the last four years, and know by experience that the orders will double each year from the same territory. Mrs. Jones orders a case of twelve 10-lb. cans of my best honey. She sells one can of it to Mrs. Brown and various other women; and if the goods are all right these neighbors are sure to want some of it.

THE DASHEENS IN A. I. ROOT'S FLORIDA HOME ABOUT APRIL 1.

The above picture was taken by one of our beekeepers who happened along at our place—Mr. H. T. Gibson, Wilmore, Ky. The dasheens shown in the picture were those sent me by the Department at Washington. They were planted about Jan. 1, but did not show above ground much until about Feb. 1. The tubers are somewhat slow about starting, and the plant itself does not make very rapid growth until settled warm weather, for it is a tropical plant. I hope to be able to give another picture, more up to date, in the near future.—A. I. Root.

In building up a mail-order business for honey, great care should be taken to please the customer. All prices should be plain, freight prepaid if possible, and instructions inclosed to all buyers to pay all overcharges of freight, if any, and that you will refund the same, which should be done at once on receipt of freight bills. If the above rules are not carried out, in many cases the customer will refuse goods because of small extra freight charges demanded by the railroad company.

All honey should be put up in a very attractive package, which means half the sale, as customers are always willing to pay a little more for goods put up under an attractive label.

Many beekeepers in this vicinity claim that the advertising of honey is not a poor man's proposition. This is where they are in error. If the honey has the quality behind it, it can be advertised in a small way at first, and in a very short time create a good demand. Look at some of the leading brands of food products that are to-day advertised, and millions of dollars' worth sold each year at fancy prices. Why? Simply because the manufacturer has produced

a first-class article and created a demand for his goods. He has made the customer want his goods and come to him for them. There is no question in selling honey but that, if every beekeeper or even one-fourth of the leading producers would get together and spend ten cents per hive every year in advertising and creating a demand for the honey, sales would increase as well as the price, and it would be a very profitable investment for all. In co-operation there is strength, and there has never been an advertising campaign of education of as good an article as honey that has failed where properly managed.

Most beekeepers figure on a wrong basis for money spent for advertising. If a beekeeper produces, say, ten tons of honey a year on an average, which he sells for \$140 per ton, suppose he spends \$100 per year in advertising the honey and sells it at \$150 per ton net to him, he will figure that he has got his advertising money back, but has done the work for nothing, which will be true for the first year, while the second year he will continue to get orders; and by spending \$50 he will sell more honey than he did in the first year. Thus the business

will grow every year; and by the fifth year he can sell five times the honey on the same amount of money for advertising.

The main idea in selling goods to any customer is to make it as easy as possible to buy. Experience has shown me that "c. o. d." and order bill of lading shipments with sight draft attached, pays. This allows a customer to go to the depot and examine the honey where he can see that the goods are all right and up to the sample sent him. I find that the refusals of such shipments amount to less than one per cent of all orders shipped.

My experience has been that the best size packages are 2-lb., 10-lb., and 60-lb. cans. The 2-lb. cans can be used by a retailer in stores, etc.; the 10-lb. can by agents who sell the honey from house to house, while the 60-lb. cans are suitable for families who consume quite a lot of honey each year. I think it is a great advantage to have as few grades as possible. If all grades were mixed together, thus making a white honey, it does away with sending samples of different grades, and customers always know what each shipment will be.

I send out samples at 10 cts. each by the thousands each year, and large sample packages weighing one pound at 20 cts. each to customers desiring to sell the honey by sample. I also have printed rules as to how I grade my honey, as follows: A water-white honey; objects can be seen for 50 feet through a one-inch bottle, such as man, etc. Printing can be read through the same bottles for white grade, etc. There is a big future for the sale of first-class honey, which can easily be developed if properly handled, and I hope to see the day when it is sold in this way.

Nordhoff, Cal.

COMPETING WITH HONEY DELIVERED FOR SIX CENTS A POUND

BY LEON C. WHEELER

The article on page 691, Nov. 1, 1912, by Frank C. Pellett, reminds me of my struggles to develop a honey market. I had a proposition to deal with, however, which was altogether different, for my competitor was selling extracted honey at 5 and 6 cts. a pound, and was delivering it at the door. I too wished to produce extracted honey; but I had no desire to sell it at any such price as that. Comb honey was no better, as it brought from 10 to 12 cts. a pound in the local markets.

The first year I had hard sledding to sell any honey at all at the price I was asking, which was 8 cts. a pound for extracted. My

competitor was selling at six, the same as before, and had already established a trade. His method of extracting, however, was against him, for he extracted his honey just as fast as it was carried in, which made it rather insipid, and there was danger of its spoiling entirely. Nobody thought any thing of that, however, as that was the kind of honey they were used to. Well, I took a lot of pains to get my honey well ripened, and to keep the dark honey separate from the light, and started out that fall to try to sell it. The price was too high, and I made very few sales, and those were mostly to people who wanted a little to last them until they could see the other fellow and buy their supply for the winter. I suppose I was criticised considerably as being pig-gish in trying to get so much for my honey.

I didn't have a very large amount of honey that year to sell, and some way I managed to sell it all; but the next year there was quite a lot more to dispose of, and I felt some fears as to the outcome. At that time I knew nothing of trying to sell in the city. My competitor, in the meantime, had boosted the price to 7 cts. He had learned a thing or two. I took his bluff, and raised mine to 9 cts. This time I was agreeably surprised to find that I could sell in a good many more places than before. Nearly all of those who had bought of me the year before were ready to order their year's supply of me that season. There was lots of kicking on the price; but in the end they would buy my honey. They would come at me about like this: "I like your honey much better than Mr. N.'s, but it seems to me your price is awful high. Why is it you can't sell just as cheap as he can?"

My answer would be something like this:

"The reason you like my honey so much better than Mr. N.'s is because I leave it on the hive to ripen, and because I take pains to put up only a good article. This makes it more expensive to produce, and I have to charge more for it. If it isn't worth the two extra cents I don't want you to buy it."

I found a few who preferred to take the cheaper honey at the smaller figure; but the good honey won out in most cases, until to-day I am selling in four out of every five places. My prices now are made according to the grade, with the average at ten cents for extracted.

There are too many small beekeepers and too small a town here to make any very great sales of honey locally, although by peddling and bringing it before the people there is a chance yet to increase the trade considerably.

As time went on I took to following the

fairs, and found it so profitable that I have kept it up ever since. At the State fairs and all large ones it is no trouble at all to sell comb honey at 20 cents per section, and extracted honey in 1-pound jars at 25 cents per jar. One gets in touch with all the fancy dealers too, and a great many who buy for their own consumption, until now it is not a question of "Where can I sell my honey with profit?" but "Where can I get the honey to fill all the orders?" This puts me just that much nearer the consumer. In fact, most of my honey is sold direct to the consumer, and the rest of it to fancy dealers who retail it. I have several customers who have already spoken for honey to be put up purposely for them next year to the amount of 500 to 1500 or 2000 lbs. each, at a figure that nets me 12½ cts. per lb. for extracted. This makes a good bargain for them, as they are securing a choice article at a reasonable figure, and at the same time I am getting more for my honey than if I were to sell in the ordinary way.

Barryton, Mich.

SELLING COMB HONEY BY WEIGHT

BY R. A. BURNETT

Mr. Root:—On p. 140, March 1, in *Stray Straws*, selling comb honey by weight or by the package is taken up both by Dr. Miller and yourself. While I may not be able to dispel the haze, I will endeavor to put certain facts before yourself and those concerned.

In Illinois the law as interpreted by the legal department of the city of Chicago (with whose representative I talked yesterday) is that any thing that implies weight must be sold by weight; but a package sealed, such as the Uneeda biscuit, can be sold as such without reference to weight; but if the purchaser asks for a pound of crackers and is given a package that weighs but six ounces, the vender is liable to a fine of from \$25 to \$200, or thereabout.

Last summer on this market several commission men were arrested for selling baskets of fruit, say of peaches, that were called pecks, half-bushels, and bushels, but which when weighed and the receptacles measured were found to be scant. Fines were imposed upon the sellers for the reason that the purchaser had asked the price of a bushel of peaches and were sold a basket said to contain a bushel.

While we have not learned of any arrests for selling a case of honey containing 24 sections representing them to be pound sections, but in reality weighing less than 24 lbs., yet we infer that the offense would be

similar when the buyer asks for a case of honey containing 24 pound sections. There are very few dealers who will buy a case of honey unless guaranteed that a certain net weight is contained therein.

Dr. Miller asks if there is any likelihood in the near future that there will be uniformity. Replying, I would say that uniformity is desired by all of us, if for nothing else than the eliminating of labor and confounding of terms. Yet there are few of us who can read accurately what is going to occur in the future. We think we see certain results; but as they are about to be realized, a new phase of the difficulty arises, and once more the certainty becomes an uncertainty.

The writer, in reviewing the history of more than thirty years in vending honey, is of the opinion that the mind of man is quite uncertain. To illustrate is quite unnecessary, as persons of middle age will have learned that in their experience.

We speak of a wood frame that is made so that it can contain 16 ounces of comb honey more or less. When the seasons are favorable, and intelligent manipulation is given to the frame, the weight of each approximates 16 ounces, usually spoken of as one-pound sections, but that the section may contain only half of this amount is also true.

In Colorado or the Rocky Mountain region it seems that the producer can come more nearly to a given weight in sections than in any other part of the country; and I have been told that the reasons are that the bees gather about so much nectar each day during the working period, the beekeepers use separators and other means for guidance of the bees in storing, and the apiaries are large enough to enable the apiarist to select sections of about an even weight and pack them in a case so that a number of cases will not vary more than a pound each, many of them being the same weight, so that the seller can say that his lot of honey averages 21 lbs. net to the case, or that there is a lot that averages 18 lbs. net.

Now, as a matter of fact, isn't this selling honey by weight when a given amount is guaranteed? What has been said applies chiefly to the producer and wholesaler. Retailers differ in their method of selling honey. Some will buy five or ten cases of honey containing 24 sections each; will pile it up on the counter or in a showcase, and sell by the section. If the honey has been graded as would be necessary under the Colorado rules, the difference in weight would not be more than from one to two ounces; but if it was under the eastern grading

rules they might vary from one to ten ounces, and in that case the retailer sells at so much a section until the heavy weights are sold out, say at 25 cts. per section, then he reduces the price to 20 cts. per section, and finally to 15 cts., to close out the light weights. Therefore it is the opinion of the writer that the true method is to buy and sell by weight; and to transact business legally in this State he has no alternative.

It is true that he may sell 100 cases of honey containing 24 sections each at \$4.00 per case if he guarantees that none of the cases will weigh less than 20 lbs. net, nor exceed 21 lbs.; but after all, weight is the basis of the transaction.

Chicago, Ill.

[The pure-food law was modified at the last session of Congress, the modification having to do with marking the weights on food packages. See the article by J. E. Crane which follows.—Ed.]

THE NEW LAW REQUIRING NET WEIGHT TO BE MARKED ON FOOD PACKAGES

BY J. E. CRANE

It may not be generally known that an amendment to the pure-food law was passed at the last session of Congress, and signed by President Taft on March 3. This amendment makes it obligatory on those putting up food for interstate commerce to see that the quantity of food packages be plainly marked on the outside of each package in terms of net weight, measure, or numerical count. This amendment does not become a law until eighteen months from March 3. This will be comparatively easy in the case of extracted honey; but who shall say just what the net weight of a section of comb honey is? Will it include the comb as well as honey? Most likely. But how about the rim of wood around the comb, or the carton or glass that is used to keep the dust and flies from soiling the comb?

The committee appointed by the secretaries of the Department of Commerce, the Treasury Department, and the Department of Agriculture, to draw up regulations for the enforcement of the new net-weight law announces that it is now ready to receive in writing recommendations and suggestions.

Middlebury, Vt.

[In a press notice sent out by the U. S. Department of Agriculture, the new national net-weight law is quoted. We give herewith, in full, the paragraph in question:

A food product will be deemed to be misbranded: "If in package form, the quantity of the contents be not plainly and conspicuously marked on the outside of the package in terms of weight, measure, or numerical count; provided, however, that reasonable variations shall be permitted, and tolerances and also exemptions as to small packages shall be established by rules and regulations made in accordance with the provisions of section three of this act."

From the above it appears that there should be no great difficulty in obtaining a ruling that will apply to comb honey.—Ed.]

BEEKEEPING IN NEW ZEALAND

BY E. G. WARD

Mr. R. N. Gidley* started beekeeping five years ago with a few colonies, and had fair success. The last two seasons have been exceptionally bad in most parts of New Zealand, 1911 and 1912 being about the worst in 20 years. Mr. Gidley went in for increase more than for honey during this bad season, and, in addition to getting no surplus, had to feed $\frac{1}{2}$ ton of sugar to carry the bees through the winter. This was done at his home at Fendalton, near Christchurch, and in the spring 1912 he moved his bees to Lakeside, about 27 miles away, taking them in a spring cart, principally during the night. Several trips were required for this, and he got them all there about the end of October. This was too late for the willows, which are plentiful round about there. The season up till the middle of November was very poor, and it was necessary to feed, as we had a lot of cold wet weather. From this on all through till now (March 9), the weather has been ideal. The spring count was 75 hives—increase 25. The crop for the season totals 9856 lbs. extracted honey, and 100 sections. The 25 increase will go into winter quarters on six or seven frames.

In addition to the honey stored, 1500 half-frames have been drawn out, and 600 full frames, so it will be seen that, if the same number of combs had been on hand, the surplus would have been much greater. The colony in the tall hive shown in the engraving on page 374, June 1, gave 417 lbs. by the end of the season. The bees were shaken on full sheets of foundation on Nov. 8, and a full super of drawn comb was added, as there were eggs in the queen-cells. This settled the swarming, and during the season they have pulled out five half-supers and one full super of foundation. After the first extracting, the combs were put back; and the total yield has been 417 lbs., and no further attempts at swarming.

The four best colonies gave as follows:

* Various views of Mr. Gidley's apiary appeared in our June 1st issue.—Ed.

417 lbs.; 275 lbs.; 257 lbs.; 235 lbs.; total for 4 colonies, 1184 lbs.

All these are leather-colored Italians. Mr. Gidley finds the leather-colored ahead of the golden every time.

Christchurch, N. Z.

ADVERTISING UNTIL THE CUSTOMERS COME TO THE HOUSE

BY GEORGE SHIBER

Continued from page 446.

veil or gloves on;" or "Why, I have seen Shiber pick up bees by the handful and not get a sting," etc.

But what of that? I don't care a cent about the wonder expressed by people to think I can handle bees. *But I do want them to know I have first-class honey for sale.* And when the public knows it, the honey-producer will have a little co-operation of one member, and will be profiting by it until the larger co-operation comes along. But don't think I am throwing rocks at the co-operative plan.

Another thing we used to do, and that was to retail it from the tank—that is, sell one, two, or as many pounds as a customer wanted. It did not pay. Another reason, honey does not keep its fine flavor long, as there is a large space for air at the top of the honey; and it hurts the flavor, even though you have a tight cover on.

Randolph, N. Y., Oct. 5.

LONGEVITY MEANS A SHORTER PERIOD, RELATIVELY, OF NON-PRODUCTIVENESS

BY LEWIS P. TANTON

In a recent issue you invite opinion upon Mr. Doolittle's suggestion as to the importance of bees being long-lived. I submit that there is no quality in the bee of to-day more desirable to select and cultivate than hardihood coupled with length of life. From the egg to maturity, 21 days, the bee is a consumer. Fourteen days further it works within the hive, still consuming—a total of 35 days a non-producer. Deducting for bad weather, intermissions in the honey-flow, and a decimation of numbers by birds and accident, it is safe to estimate that the average working days of the bee (in the honey-flow season) will not exceed 30. Within that period this little worker must produce food to supply its successor during the 35 days of its incubation and development, food for its own maintenance, provide sufficient stores to last at least six months in winter, and to contribute what every beekeeper is looking for—a generous

surplus. From these facts I argue that every hour we can add to the working period of a bee's existence is a positive and untaxed profit. To illustrate this:

I imported a beautiful yellow queen and introduced her to a three-frame nucleus. As a producer of handsome and busy yellow workers she eclipsed any thing I ever witnessed. The frames filled from top to bottom and to the outer edge with healthy brood. I allowed her to increase until three body supers were full of brood and bees. I christened her my "thousand-dollar queen," and the only difficulty ahead was how to get so many bees into a compass small enough to winter. At the close of the season I reduced my appreciation of her value down to fifty cents, and she was worth that appraisement only for the lesson she taught. There was scarcely any honey in the hive. All had been consumed in brood-rearing, and there were not enough bees to fill one super fairly. I fed them; but in spring all were dead. The bees were good workers, quiet and healthy, yet short-lived, and, as a result, their whole period of field activity was insufficient to produce the surplus of stores, and what I would call the surplus life necessary to maintain the healthy existence of the colony.

This view of the question revives inquiry as to which is the best race of bees. The Italian, because of its adaptability to the largest area, the uniformity of its character for docility, and its reputation for industry, coequal with that of any other race, has won for itself the largest number of admirers. The great Creator in his infinite wisdom had the same just measure of the world's requirements in shaping the bee as in the other countless forms of life, and each of their varied forms and characters was destined for a work which the other was not adapted for.

Place my beautiful yellow prolific queen in an equable southern temperature with an abundance of nectar near at hand, and confine her brood-chamber to one or at the most two supers, and her value would not have met such a sweeping and spontaneous discount. In rugged mountainous localities where the bee is up against hardship and every variety of weather and climate, the Italian does not boast of so many friends. In the northern portions of Maine, in all the colder sections of Canada and the Northern States, the black bee or its crosses are the most in favor. Even in places of moderate temperature the three-banded and the leather-colored are recognized as the most profitable and reliable.

Now, why is it that the German bees succeed in certain localities so much better

than the vaunted Italians? They do not work as early in the morning nor as late in the evening; they carry on an average less brood in the hive, and yet in the end they produce as much surplus honey as other races would do under like conditions. I have not tested for myself, but I strongly suspect that the secret lies in the longer life and in the more extended working period of the black bee, and because less of the worker's labor is expended in the raising of brood and young bees, to die out again almost before they have gathered honey enough to pay for their keep.

There seem to be features in the character of bees suggestive of their nativity. Why do the black bees hasten under cover quickly at the approach of darkness, or when clouds loom up? and why do they scamper nervously away and drop like molasses from the combs when being handled? Is not this indicative of a boisterous place of origin and a desire to get in out of the cold or to escape impending storms? The Italian, on the other hand, is quiet and tractable, spreading itself evenly over the comb, and continuing its work almost regardless of disturbance. Is not this an exhibition of its inherent confidence in the blue skies and the balmy atmosphere of its native Italy?

Concluding, I am impressed with the belief that breeding for longevity and hardiness should call for the best skill of our apicultural specialists. I would further suggest that dogmatic conclusions as to the value of any particular race of bees for universal use be set aside, and a study of the adaptability of the different races to special localities be taken up. These features being satisfactorily understood, our bee journals, advisers, and supply-houses, instead of dumping their own favorite and probably successful race upon us would enrich us with bees suitable to our locality and our needs.

Charlottetown, P. E. I., Feb. 1.

OPEN-AIR FEEDING

BY MAJOR SHALLARD

I have been much interested in your plan of feeding, given in the A B C and X Y Z, by hanging kerosene-tins with perforated bottoms up in the air. But you state in the same place, "If the syrup were fed in open cans, thousands of bees would be drowned." This is not so. I once had an apiary of 250 colonies where the crop had gone off right in the middle of the season. The hives were short of stores, and the queens were ceasing

to lay. I knew this would not do. As it was an out-apiary I had no time to go to feed each colony individually, so I put out three of the largest galvanized iron washing-tubs, put the end of a kerosene-case in each for a float, spread a large sheet of hessian (coarse sacking) over the whole lot, leaving enough sag to allow it to go right to the bottom of the tub when it was empty. I filled the tubs to the top with honey and water, half and half.

I never saw more than a dozen or two dead bees in any of the tubs at any time. The hessian would float on the board, and the capillary attraction would wet it right up to the edge of the tub, even if the latter was half empty; consequently the bees had a large surface to alight on, and they did not get drowned. For that matter there was no place to get drowned, as there was no pool of honey anywhere, except the damp hessian. There was no robbing, although the tubs were put right among the hives. Before I had quite finished giving them the amount I had arranged for, the honey-flow started and the tubs were deserted.

It paid me well; and while I had a good population in each hive, and got a good crop, my neighbors' bees built up only strong enough to go into winter quarters, and got no surplus at all.

You will probably say they would have robbed if the flow had not come on. I do not think so. I think they would if the tubs were removed; but if left there they would simply visit them until they were thoroughly satisfied there was no more honey there, and then they would settle down.

If a comb of honey is left out and the bees begin robbing it properly, remove that comb and you will cause robbing; but leave it there and let the bees empty it, and when they are satisfied that the honey is all gone, they will abandon it and will settle down quickly.

If a half-story of honey is left out and forgotten while taking off the honey to extract, and I find the bees starting to rob it, I get it away quickly; but I put another half-story, with a little honey on it, in its place. Let them satisfy themselves that there is no more, and they will go away; but take it away, and they go looking for it and start robbing the other hives.

South Woodburn, N. S. W., Australia.

Rope Attracts Swarms

I had a queen among eleven whose eggs would not hatch this spring. I also notice that bees in swarming will be attracted by a rope wrapped on a limb or bush if placed in a conspicuous place.

Heads of Grain from Different Fields

Grading Extracted Honey by Means of a Standard System of Colors

The matter of grading honey correctly is a question of paramount importance to every one handling either comb or extracted honey. Mr. G. F. DeMuth, of the Bureau of Entomology, is quoted in your report of the National Association at Cincinnati as suggesting a scheme of colored cards to be used as a standard of comparison by which to describe any grade of comb honey as to color. This matter of a standard color-guide has been in my mind for some time; and since the subject has been broached publicly I am prompted to give my idea in the form of a suggestion relating to extracted honey only.

When extracted honey is viewed by transmitted light (that is, by the light through the honey), the color is lighter when the body of honey is small, and darker in proportion to the increase in the body. This, in the first place, suggested to my mind the advantage of always viewing the specimen through glass containers having the same diameter or distance through, so that, whether the specimen be light or dark, its actual color is shown to a certainty, and sample after sample can be compared to a nicety.

When this idea had been well considered I could not but marvel that the business of judging the color of honey has been done in the haphazard way it has ever since extracted honey has been a marketable product. The general use of a standard prescribed container for observing honey to be judged, say a test-tube $\frac{3}{4}$ inch in diameter, would put the question upon a fairly reliable universal basis. Assuming that this were done, there yet remains the human factor to be considered, for the specimen naturally looks to the seller much lighter than it does to the dealer. The possibility of a dispute or at least dissatisfaction can be avoided by the use of an accepted standard color-guide, to be viewed alongside the honey contained in standard-sized test-tube.

It seems to me that it would be appropriate for the National Association to select and make official and standard such a scale of colors made in glass (which is most unchangeable), the original to be kept by the secretary as the standard. The Association could supply certified duplicates to all who might desire to purchase. Every producer of extracted, and every dealer, should be provided with such a means of grading the product properly beyond question. Such a color scale might be made a permanent part of the standard-sized test-tube, thereby simplifying all operations.

The matter of grading extracted honey would be thus made an exact science. Any person not color-blind could grade honey. The seller could know exactly his grade before shipping, thereby avoiding any hocus pocus by the consignee. The demand for extracted honey is increasing, and the importance of standardizing the method of grading increases correspondingly; so that it would seem that this is a matter deserving attention and action.

Comb and Extracted Selling for the Same Price

I started about ten years ago with two stocks of bees, because I had a piece of land of about two acres on which I grew small fruits such as strawberries, raspberries, and black currants. I also had a small orchard of plum trees. I had a shop in the main street of the town, so I thought if I was clever enough to get any honey I should be able to sell it retail over the counter and get full price for it. I have gradually increased my apiary from two to 33 colonies of bees because I found I could make it pay, and also sell all the honey I could get. When I started I made up my mind to master the practical side of beekeeping; so I joined the county associa-

tion of beekeepers, bought the British Beekeepers' Guide-book, the A B C and X Y Z of Bee Culture, and read up all I could about bees. Each year I have bought more books and have taken bee journals regularly, so as to glean all I can about the theory and practice of beekeeping.

I can sell at retail all the honey I can get, and most years have to buy some more in order to supply orders. It is put up in $\frac{1}{2}$ and 1 lb. screw-capped bottles, and is sold at 24 cents per lb. I also sell the sections at the same price. The seconds, or those off grade, are all eaten at home. I make a profit on an average of about five dollars per hive each year, and some years more. This year was the worst for several seasons, the average yield of honey being 15 lbs. per colony. Last year my average yield was 40 lbs., the highest individual hive giving 72 lbs.

My district is the noted fruit-growing district of Evesham, in Worcestershire, and stretches for several miles on either side of the town. The farms are gradually giving way to fruit culture and vegetable-growing, so you see my honey is a mixture of fruit, honey clover, raspberry, peas, beans, etc. The fruit blossom comes early, and the bees build up quickly, and some years fill a super on each hive from fruit blossoms. I do not get any light honey around here. It is generally medium-colored, of a good consistency, and rich, thick, and of good flavor.

I have gone in for showing, and have taken two silver and three bronze medals, and about 35 money prizes, mostly at local or county shows. The exhibiting is a great help in selling my honey; and if I have a big lot I advertise in the local papers, and give a guarantee with every pound of honey.

WM. J. WOOLLEY, JR.

Evesham, England, Dec. 2, 1912.

Sending Honey by Parcel Post

On p. 94, Feb. 1, I note that different packages are used in Europe for sending honey by parcel post. I have been sending honey thus for about three weeks, and have mailed about one can a day. One 11-lb. can was sent to the third zone; some were also sent into Massachusetts. All report that it goes through well, and that the honey is fine. Of course I am sending out nothing but the best of honey.

I am using a can made in Franklinville, N. Y. It has a $2\frac{1}{2}$ -inch screw top, and is tight when screwed down. I make a light wooden crate. The ends are $\frac{1}{4}$ thick, and the size of the can ends. I then nail two strips on a side about $\frac{1}{4}$ inch from the corner. When it is all nailed I tie a strong string around each end just back of the end; and as I nail the strip a little from the corner, the end corner sticks out so that the string can't slip off. I have some strips of tin 8-16 wide, and long enough to go around after it is all nailed, which I intend to try.

What we want is a reduced rate. It is quite surprising to see how short a distance a 50-mile zone is when you want to send a package. It is necessary to take the precaution to have every thing tight and in good shape. I have been wondering how far one of these packages would go safely.

Alfalfa Honey Usually Granulates Quickly

May 15, p. 329, Mr. J. E. Crane stands corrected about alfalfa honey granulating. We know from many years' experience with it that alfalfa honey granulates the quickest of any kind we have ever had any thing to do with. Our experience started in Wisconsin; after which we spent thirteen years in Michigan, two in California, five in Nebraska, and for seventeen years have been in Colorado.

GAIL CROWFOOT.

Eggs and Young Larvæ Do Cause the Disappearance of the Virgin; a Supporter of A. C. Miller

The above has reference to p. 796, Dec. 1, by Arthur C. Miller. I reckon I owe him something for that article. I have been losing more young queens for years than I liked. I never could understand why, and we had been told so often to give young brood, and not warned *not* to give eggs, that it had become a fact in my mind that it was the proper thing to do.

I have had many people apply to me to know why their young queens disappeared, and I could not tell them. No doubt it was the eggs. What the writer says about Henry Alley waiting three days before giving a cell is like an illuminating lamp to me. When I first started beekeeping—in fact, before I owned a hive—I read and digested "Manual of Beekeeping" by John Hunter. In this book he says, "After removing a queen, do not give a cell for 72 hours." He said he did not know why, but 72 appeared to be the magic number of hours to wait. For years I acted on this advice, and gave no cells for three days.

These were ripe cells reared on the Alley plan, and they would hatch within a few hours of insertion. After pursuing this method successfully, and not losing more than Mr. Miller says is the correct percentage, the cell-protector was invented. I adopted it to save those three days, and I lost anywhere from 25 to 50 per cent of my queens.

Even then I did not see what the trouble was. There might not be any thing in Mr. Arthur C. Miller's contention; but it looks feasible enough to me, and I am going back to the three-days' wait, keeping all eggs out of a hive containing a virgin.

MAJOR SHALLARD.

South Woodburn, N. S. W., Australia.

A Satisfactory Experience as a Helper in the Empire State

The account of the treatment of employees on a California ranch as given by "Subscriber," page 58, Jan. 15, contrasts strongly with the treatment of employees in the Empire State—at least such has been my experience. It was my privilege to spend most of the season of 1912 with a professional beekeeper of Tompkins' Co. I began my duties about April 1, and was well received and splendidly treated from the first. I received \$25.00 a month, with room and board, and ordinary washing included. I was given a very comfortable room, and the board was fine; in fact, had I been a member of the family I could not have been more generously used.

The work at the yards, of which we ran ten, was strenuous, and I was made to feel that I was expected to earn my money; but that, of course, was no more than I anticipated.

Only once during the summer was I sharply reproved. That was when I set an upper story containing a queen in deep grass. As I had been repeatedly warned against doing this, I did not blame my employer for speaking quickly. Of course there were several mistakes which were corrected by my employer, but he usually spoke quietly, and very rarely allowed his temper to manifest itself.

I left my place in September, feeling that I had spent a profitable as well as pleasant season. As I anticipate entering the bee business, the experience gained will be a great help to me.

Spencer, N. Y., Feb. 6.

"SUBSCRIBER."

A Correction

My article, page 335, May 15, is different from what I wrote. Where it reads, "If no cells were started at the time of removing the queen, removing the two combs once," etc., it should read: "Removing the cells once is all that will be required before returning the queen and brood."

Honey, c Falls, N. Y., June 7. A. C. GILBERT.

Photographs of Swarms, etc., an Aid in Selling Honey

For the benefit of those who have any trouble in disposing of their honey I should like to suggest a little scheme that helped to a very great extent in securing orders in about nine out of ten stores in which I solicited.

By means of a camera, and with the help of the bees, here is my plan:

During the summer I take a few pictures of bees while clustered on the tree after swarming, or of different manipulations which will prove very interesting, and hold the buyers' interest. These help considerably, and will keep you busy answering some of the extremely laughable inquiries that people will sometimes ask in regard to bees.

When I first started in I took care to let the grocer see me whenever I was stung, thus proving that I was a beekeeper.

Chicago, Nov. 2.

TIMOTHY P. O'DONNELL.

Drones instead of Queens

Please tell us what you would do if you had a neighbor, much(?) learned in bee culture, who would ask permission to get a queen from your yard whenever he had a swarm at home, and after receiving your consent would invariably march off in triumph with a drone? Understand me, he is too *practical* to read GLEANINGS. Will you please make it more convincing that the "moth" does not destroy bees in a normal condition?

I find it impossible to make my beekeeping friends believe that the moth is not the most deadly enemy of the bee industry.

Guilford, Kan., May 9.

HERSCHEL SHORT.

[Ignorance is certainly bliss in case of your neighbor, who thinks he has a queen when he has a drone. However, after one trial we should think he would find out his mistake.]

It is true that there are still beekeepers who are wasting their time fussing with moth-traps, moth-hives, etc., for the purpose of keeping moths away from bees, but all such are becoming fewer and fewer, as it becomes better and better known that strong vigorous colonies, especially of Italians, do not need any help in protecting the hives from the ravages of the bee-moth.—Ed.]

Paste for Sticking Labels on Tin

April 1, p. 232, Mr. G. A. Barbisch, of La Crescent, Minn., wants to know whether there is a preparation which will make labels stick to tin. I am pleased to say that there is, no matter how small the label. If it is of any use to the readers of GLEANINGS they are welcome to use it. It is as follows:

Make a flour paste, being sure that it is thoroughly cooked. To a pint of paste stir in a quarter of a teaspoonful of powdered alum. Avoid too much alum, as it will cause the tin to rust and the stain to come through the label. Label the tins before filling with honey. I have used this paste for ten years, and never yet had a label come off.

Owen Sound, Ont.

CHRIS. GRIMOLDBY.

Strengthening Honey-cases

For a number of years I have used shipping cases with a cross-piece $\frac{3}{4}$ inch thick through the center. I find that it reinforces the case, certainly half. I have no trouble with honey breaking from the sections. Others can do as well if they will use judgment in packing, being particular not to have hard lumps of straw or excelsior under the middle of those weak and frail cases that are used. Think of beemen asking that that frail box take care of our honey on the railroad. Does it look as if we knew how to take care of bees?

Theresa, N. Y.

Our Homes

A. I. ROOT

Ask, and it shall be given you; seek, and ye shall find; knock, and it shall be opened unto you.—MATT. 7:7.

And it shall come to pass that, before they call, I will answer; and while they are yet speaking I will hear.—ISA. 65:24.

Hitherto have ye asked nothing in my name; ask, and ye shall receive, that your joy may be full.—JOHN 16:24.

The following letter from one of our subscribers explains itself:

In your account of questioning the Savior, you claim to have got a "plain, distinct, decided 'No'" to each question. Why, then, do you go to Mr. Rood with some of your questions? If I had the use of a few pages in GLEANINGS each issue, and could go to the Savior with my questions with assurance of such prompt answers, I would ask him about many things the whole world has wanted to know throughout the ages, and give the knowledge thus gained to a waiting world. Even in such comparatively unimportant matters as beekeeping, gardening, poultry, health, eating, authoritative knowledge like that you receive from the Savior would be of vastly more value than any you are now publishing, as infinite knowledge is of more value than finite. You could easily double your circulation in a few months, and do an immense amount of good for temperance and religion. I should be pleased to read your answer to this question in GLEANINGS or in a letter.

My good friend, I am glad you have asked this question, because I may have been a little careless by leaving the inference to the effect that I *always* receive answers to my prayers in such a plain and emphatic way. I believe it is generally recognized that God answers prayer in different ways. Sometimes, as in the case mentioned, the one who is praying, almost as soon as the words are uttered, receives an enlightened conscience that enables him to see with his spiritual eyes, if I may use the expression, that he had been (at least for the time being) out of the straight and narrow path; or, in other words, that he had been unconsciously influenced by Satan to see things in a distorted light.

In our first text the dear Savior in his own words declares plainly that our prayers shall be answered. He says, "Seek, and ye shall find; knock, and it shall be opened unto you." Now, there are times—in fact, most of the time—when the great Father sees fit to let us work awhile, before getting what we ask for. In my work with the dictaphone God seemed pleased, if you will excuse the expression, to let me keep on at work, and be baffled again and again, before he told me or showed me how to get the results I was longing for. In the same way a good parent, instead of giving his beloved child every thing he asks for, shows him how he can get the desired thing by a little hard work.

In our recent studies of the history of Joseph we see how he was led from being a humble shepherd lad to the highest position in Egypt, next to the king; and Joseph had perplexities and disappointments so that, had it not been for his unwavering faith in God, he never could have stood for ages before the world as one of the greatest characters that the history of humanity furnishes.

Let us now go back and consider my trouble with the mischievous schoolboys. I had prayed over the matter several times—that is, after I had begun to see that I was getting into an unchristianlike frame of mind. I not only asked God's guidance but consulted my friend Rood because he was superintendent of the Sunday-school, and was universally recognized as a Christian man in that whole vicinity. My first impression was that the boys should be arrested for interfering. After friend Rood had declared that, if it were his case, he would leave the machine and "chase them down," I still felt uneasy and troubled about it. Had they been annoying other people in the same way it would have been a different thing; and when I asked the Lord on my knees, as I told you, if I should get out of the auto and go after the boys and get their names so I could make complaint, the answer came strong and clear, as I have told you. In other words, I could see while there on my knees that I should be out of place in any such proceedings, especially under the circumstances. Again I asked the question, or, if you choose, asked the Lord, to direct me in deciding whether I should report them to the sheriff, after I succeeded in getting their names; and the answer came as before, or, if you choose to put it differently, in that prayerful attitude where I was praying for the good of the boys as well as for myself it became *very clear* to my mind that I should be out of place or out of character, as the author of these Home papers, in reporting the boys to the police authorities, just because they annoyed *me* and nobody else. Good common sense seemed to declare that I had unconsciously gotten into a strife or quarrel with the schoolboys or the boys in the street.

Let me now tell you something that I did not tell you before. When they were annoying me by climbing on behind but not getting off when I ordered them off I decided I would get a yardstick which would enable me to reach them, and I actually went and bought one and laid it on the

seat; but before I had even flourished it toward them I asked the Lord if such a thing would have his approval. The answer came very plainly as before, and I never used the stick at all. I took it off the seat of the auto as soon as I got home. The answer came partly through a recollection of those precious and beautiful texts that I have already quoted: "Love ye your enemies; do good to them that hate you;" and "if thine enemy smite thee on one cheek, turn to him the other also." The implication would be that I should be forgetting my Christian character or standing, if I so much as even *flourished* the yardstick toward them. At every point I was handicapped—that is, handicapped so far as *striking back* was concerned; and I confess to you that it went awfully "agin the grain," as my poor friend Fred expressed it as we knelt together on the stone floor of the old Medina jail.

Many times our prayers are answered by not being answered at all; or let us put it this way: A child often asks for things that would do him harm. The wise parent refuses the request, and many times without explaining why. When Joseph was cast into the pit he no doubt prayed over the matter; and the same way when he was sold as a slave into Egypt; and again when he was cast into a dungeon for refusing to betray the sacred trust that had been conferred on him; and, if I am correct, he was something like *two years* in prison without any prospect, so far as he could see, that his prayers were answered or that his liberty would be granted. God saw fit to test his faith. In the same way Joseph seemed to his brethren hard and cruel; but he was only testing *them* and sifting them to see whether they had repented or reformed since he had lost sight of them. Although Paul had many wonderful answers to prayer, there was one thing he prayed about all his life, so far as we know; and yet his faith in the loving Father wavered not. God did not see fit to remove the thorn in the flesh, although he had, in answer to prayer, given him grace to bear it.

My good friend, I *have* asked the Lord repeatedly to guide me and to give me wisdom in regard to beekeeping, gardening, poultry, health, eating, etc.; and I would gladly submit the matter to the readers of GLEANINGS as to whether my prayers have been answered or not. The large circulation of our journal at present, the many kind words that come for my department, urging me to keep it up, is to me abundant proof that my prayers *have* not only been answered but are still being answered. I think you will agree with me that we have abun-

dant reason to thank God for the wonderful progress that is being made in the things you have mentioned, not forgetting temperance and religion; and my impression is that this progress has come largely in answer to earnest and faithful prayer. Not only is the Bible being read now in a way that it has not been before since the world began, but there are more people *praying* than ever before.

Our second text admonishes us that God prepares and plans his answers, even before the prayer is uttered. How do we know that God in his infinite love and goodness did not plan letting those boys full of mischief test my Christianity? One of the writers in the *Sunday School Times* suggests that, after we finish the study of the history of Joseph, we should take a birdseye view of the whole transaction. Sometimes in traveling we get to the summit of a hill where we can look back over the winding road that we have traveled over during the day. On the way to California you can many times look back and see how the railroad has twisted here and there in order to reach a certain point. Well, we want to take a birdseye view of that story of Joseph in the same way, and see the mysterious and crooked ways through which Joseph was led amid the perplexities and disappointments at the hands of his brothers, and yet which ended in placing him on the throne of Egypt beside Pharaoh himself as prime minister, and still later as the savior of the nation. Joseph *held fast* to the faith he had in God's many and gracious promises, and he had his reward.

Our last text contains another wonderful piece of information. In our prayer we should ask for that which we think we need and for that which is best for us. Jesus tells us to ask it in his name, and that is why we so often hear the expression at the close of a prayer, "in Jesus' name," etc. He says again, "Ask, and ye shall receive." This implies that, if the answer does not come all at once, as it does sometimes, by an enlightened conscience and intellect we know it *will* come eventually. Then he finished the sentence by saying, "That your joy may be full;" and I confess that I never *fully* realized what that means until this very moment. After having that wicked and spiteful spirit that I felt toward the boys who annoyed me—after having that bad spirit *banished* by prayer, I felt happy. And, my good friends, whenever any of you get to feeling spiteful and unpleasant toward your neighbors, prayer *will* dispel such feelings. Do you not agree with me? And when you are inclined to get into such a frame of mind again, just breathe this

little prayer to the dear Savior: "Create in me a clean heart, O God, and renew a right spirit within me." I told you about how my wife was startled because I laughed aloud when reading the Bible. I laughed because I felt satisfied that I had found a *remedy* for my troubles. When I came out ahead of the squash-bugs and saved my plants I no doubt laughed about it.

Let me now quote once more from the *Sunday School Times*. Please notice again the expression in our last text—"That your joy may be full." Wm. H. Ridgeway, in speaking about the joy of salvation, says:

"The joy of salvation." I would have no use for religion at all if there were not more fun in it than in any thing else on earth.

And I want to say amen to the above. True religion, which I have been trying in my feeble way to hold up before you, is actually more "fun" than any thing else.

FORTY YEARS WITH THE "LITTLE BUSY BEE."

The above heading was prompted by a trip I have just taken, June 17, out to one of our out-apiaries down on the river bottom, three or four miles away. Thanks to a kind Providence, honey is coming in very much as it did a year ago; and as a "gang" were going down to take off the first honey of the season I was asked to go along. In about half an hour's time our boys took off toward half a ton of honey, all from the upper stories, so there was no brood in any of the combs. Mr. Marchant, the foreman, opened the hives and lifted out the heavy well-filled combs while a boy drove the bees down with a smoker as much as possible. After Mr. Marchant had shaken off the bees in front of the hive an attendant who stood ready with a suitable brush brushed off all the remaining bees. The comb was then passed over to a fourth man, who placed it in an empty super. As soon as he received nine heavy combs they were carried directly to the auto truck until the load was made up. Then the truck was quickly run to the extracting-house at the Home of the Honeybees. You see the auto truck could be backed right up into the apiary close to where the men were working. It did not matter whether the air was full of flying bees or not. There were no horses to be stung. As the vehicle is equipped not only with rubber tires but steel springs, the load of honey was conveyed quickly and safely three miles or more away on the auto truck.

Forty years ago there were a good many jokes at my expense because of my enthusiasm for the future of bee culture. Our older readers will remember the picture I

gave of the hexagonal apiary.* By the way, that same apiary was a good deal on the plan of the modern "convergent poultry-yard." It was designed to save steps. You will recall that I had a picture of a little railway track and a car on this track to run up to the honey-house located in the center. This car was to carry the honey far enough from the extracting-house so it could be loaded on to a wagon without having the horses stung, etc.

Well, although I did have some wild visions in regard to the outcome of bee culture, I did not dream of an automobile for helping the beekeeper, for no such thing was then known or even dreamed of at that time. Perhaps I might remark that this is the first time we have gathered our honey from out-apiaries and brought it in on an auto truck. Heretofore we have carried the extractor around the apiaries and brought in the honey in cans; but you who have tried it know it is a big job to lug that extracting-outfit away out in the country and move it from one apiary to another. Ernest remarked this morning that he had been studying on the problem, and he was wondering whether the auto truck could not bring in the filled combs, and carry them back cheaper, rather than to carry a convenient extracting-outfit around to each apiary. When the extracting is done at the home or the center apiary we can use a gasoline-engine for power, which would be quite difficult if we had to move it around; and with this management we can have things fixed up in good shape for extracting, uncapping, etc. Of course, this necessitates having a set of empty combs; but this is an easy matter, especially when we extract only from upper stories and prevent the queen from having access to the combs above.

There is so much going on at the Home of the Honeybees just now that I feel sometimes like rubbing my eyes as did Rip Van Winkle, to be sure that I am awake. I suggested taking these heavy combs full of honey up to the honey and wax room, and have them do the extracting. Their force of women folks one would expect might be a little more tidy than a lot of men and boys. But what do you think was the reason given for not doing so? Why, just this: Orders are coming in so thick and fast for foundation that all hands have almost had to drop the work of honey and make foundation. Besides, there would not be any room there for the extracting business; and yet this wax and honey building covers a piece of ground 60 by 150 feet.

From the 50 colonies in that one apiary we took 1600 lbs. from our first extracting.

* Reproduced on the cover of Feb. 1st issue.—Ed.

This result, 32 lbs. per colony, as early as the middle of June, is certainly pretty good.

May the Lord be praised for what I have been privileged to live and see accomplished with the honeybees.

High-pressure Gardening

THE DASHEEN, AND SOMETHING MORE ABOUT IT.

On page 240 you will find a glimpse of my Florida garden, and of the dasheens about three months after planting. The ground had been mostly cleared off after growing some other crop. Just over my left shoulder, if you look carefully, you will get a glimpse of our Golden Bantam sweet corn, which our neighbors write me is the best sweet corn they ever tested. I think the Golden Bantam is the most suitable for growing sweet corn in Florida in winter, because it is much harder than the other varieties of sweet corn, and will stand the cold weather better.

Now in regard to the dasheen. Below is a clipping from the *Country Gentleman* for June 7. This same article contains a picture of dasheen shoots grown in a greenhouse in Michigan. Although I have not tested any of the shoots to be used like asparagus, I am fully satisfied they will be excellent food; for in hoeing about my plants I have occasionally chopped off a sprout with my hoe; and on chewing these white crisp shoots I have found them to be very rich and sweet, and almost exactly like raw asparagus. On page 240 of our issue for April 1 you will see there is a reference to the dasheen as a substitute for asparagus. It is somewhat surprising, at least to me, that none of our great seedsmen have not as yet taken hold of the dasheen and exploited it as they usually do new vegetables. The dasheen, like the calla lily, wants a very rich soil with a great abundance of humus and plenty of water; and wherever things are favorable I am told they frequently grow as high as a man's head.

A great deal has been written about the dasheen—that new root crop for the South. Now it appears that more will be written, and for good reason.

It is generally known that the dasheen has all the goodness of the common spud, with even greater food value; that the tubers can be baked, French fried, mashed, croqueted, and used for stuffing roasts. It is also generally known that a good flour is being manufactured from the dasheen; that the leaves of the plant make an excellent substitute for spinach and other greens; that plantings have yielded as high as 400 bushels of tubers to the acre.

That should be enough for any plant that has been experimented with in this country for only five or six years. But now the dasheen has added yet another chapter to its catalog of possibilities. The shoots of the plant have been tried out as a food,

and they have filled the bill to the satisfaction of all who have taken a hand in the experiment.

Ordinarily the shoots that eventually bear the big "elephant-ear" leaves are green and far from tempting. Perhaps they would never serve as a human food if they were experimented with in the natural green condition.

But recently the Division of Foreign Seed and Plant Introduction of the United States Department of Agriculture secured the co-operation of a man in Michigan and had him box in the growing dasheens so that light would be excluded from the stems. The result was a complete bleaching of these, and a product more tender and tempting than was hoped for.

The bleached stems were cut, packed, and shipped to Washington. David Fairchild, agricultural explorer for this division of the department, had them cooked, and served at a banquet. He took a long chance, for he didn't believe in trying out this experiment on the "dog." Well, the dasheen sprouts tasted good—something like asparagus—and were served like asparagus. Everybody liked them. And now Mr. Fairchild and the rest of his force are going in for a more thorough investigation of this new dasheen.

These shoots—or, rather, the dasheen plantings—were forced in a greenhouse. It was found that several crops could be grown in a season. Of course it is possible that such a process of growing this new food would not pay; but Mr. Fairchild and his corps feel that the same results will eventually be secured in the field, earth banking taking the place of boxing to effect the bleaching.

DASHEEN FLOUR—SEE A. I. ROOT'S SPECIAL NOTICES FOR JUNE 15.

The dasheen flour mentioned in our last issue was finally forwarded from Bradenton, Fla. The Department at Washington informed me that they have no more to send out this season. Well, while we are well pleased with the dasheen flour for cooking purposes I am not prepared at present to speak so extravagantly in regard to it as I did of the first baked dasheen tubers last January. Let me explain.

I got my first bag of dasheens on Christmas eve, as you will remember; and some time in March I secured five bushels from the Development Co. at Brookville, Fla. Now, these last five bushels were already sprouted more or less, and some of them were wilted somewhat. We all know that a sprouted and soft Irish potato late in the spring is not expected to be of first quality for table use, and it was so with the samples selected from the five bushels I bought. They were nothing near equal to the first one, which was hard and firm and solid. Well, this dasheen flour tasted a little like the wilted dasheens when cooked. We have tried them for making biscuit with

half white flour, also for making cookies. We passed them around the neighborhood, and they all voted them fine—better than biscuits and cookies made entirely of wheat flour. But the best results were attained with pancakes of one-fourth graham flour and three-fourths of dasheen flour. These, with maple molasses, were certainly delicious.

Will dasheen flour ever be a successful rival to common wheat flour? It looks to me quite likely; for I believe it is certainly a more nourishing food if possible. Then consider that 50 bushels per acre is a big crop of wheat, and few farmers come up to that. But the dasheen has been made to yield at the rate of 500 to 800 bushels.

Here is another one of my "happy surprises." The Department at Washington has just put out a very pretty bulletin of twelve pages entitled "The Dasheen, a Root Crop for the Southern States." It contains two pictures of the growing crop and a very nice picture of the tubers. From this bulletin I make the following extract:

The nutty flavor of the tubers gives them a peculiar palatability which has struck the fancy of a large number of persons. The higher nitrogenous and starchy character gives them an advantage as food that would seem to make the plant, when compared with the potato, an even more valuable food-producer.

RECIPES FOR THE PREPARATION OF THE DASHEEN.

This vegetable is a staple article of food for millions of people in tropical and subtropical countries. In general it is used in the different ways in which the white potato is used. It may also be candied like the sweet potato. The flesh of the corms and large tubers is frequently somewhat gray or violet when cooked, but this does not affect the flavor.

When uncooked dasheens are being scraped or pared they should be handled in water to which a teaspoonful of sal soda to the quart has been added, in order to prevent irritation to the hands.

BAKED DASHEENS.

Dasheens, large or small, may be baked like potatoes, in a quick oven. They should first be washed and scrubbed to remove the fibrous part of the skin. When practicable to do so it is often desirable to scrape the dasheens before baking, as they are then more convenient for eating, and the soft crust which forms when they are properly baked is particularly delicious. The corms may be cut in half from top to base in order to lessen the time needed for baking. The time required is about the same as for potatoes of the same size. They should be served hot. Season with salt and plenty of butter, and pepper if desired. Gravy instead of butter may be used.

The dasheen when properly baked and served is mealy, and the flavor is much like that of the white potato, but more or less suggestive of chestnuts. If not overbaked, the skin when properly scrubbed or scraped beforehand will be found of delicious flavor. As the dasheen is drier than the potato it requires more butter.

Additional copies of this publication may be procured from the Superintendent of Documents, Government Printing Office, Washington, D. C., at 5 cts. per copy.

The dasheen is used in enormous quantities in Cuba, where it is known by the Spanish name of malanga.

THE HIGH COST OF LIVING; HOW OUR MISSIONARIES MAY HELP TO REDUCE IT.

Friend Root:—I presume you will not remember meeting me in Medina some ten or twelve years ago; but knowing that you are interested in our work, and have taken a part in it, I think I may venture to address you as above. It was through your kindness in sending me a letter of introduction to the Wright Brothers, while I was at home on furlough year before last, that I met Mr. Orville Wright (also father and sister), and saw him fly. The fact that GLEANINGS has been coming to me for years I take to be a substantial proof of the A. I. Root Company's interest in foreign missions in general and in our mission in particular. I have read your department with much interest and pleasure; and seeing your interest in every good work I can only regard you as one of our number—a missionary. I have often felt like writing you after reading your kind and helpful messages, but have felt that it would not be wise to impose on your time; but upon reading what you say about the "dasheen" in GLEANINGS for March 1, 1913, and noticing that I am left out of your proposal to send a "dasheen tuber to every reader of GLEANINGS—that is, to every one who sends the subscription price for one year," since I receive it free, I have decided to write to see if I can not arrange to receive a tuber also.

Now, I suppose we must have something like the "dasheen," only we know it by the name "amadumbe." There are several varieties here—some very large, but almost worthless; others smaller, and highly esteemed as food. By the time this reaches you and I can receive a reply from you, our amadumbe will be about ripe, I think, and it will also be a favorable time for sending them so far by post. Now, if you would like to try some of our best variety of amadumbe, and compare them with the dasheen, and will so notify me, I will endeavor to send you a sample packet registered. We also have very nice sweet potatoes here. One variety we prize higher than the others, because of its very vigorous and quick growth combined with excellent eating qualities. It is quite the opposite of "vineless," but my experience has been the less vine the less vigor. If you would like a sample of these also, I will send them. Now, if in exchange for the above-mentioned samples you are willing to put me on the list of recipients of one of the Trinidad dasheen tubers (I should like to see how it compares with our amadumbe), I shall be pleased; otherwise I think I shall have to send my subscription to GLEANINGS.

I, too, enjoy hunting up "God's gifts."

I am addressing you at Medina, as this will reach you in summer; but presume the samples should go to your Florida address.

W. L. THOMPSON, M. D.

Mount Silinda, Masetter, Rhodesia, South Africa,
April 25, 1913.

My good friend, I was not only delighted to receive your kind words and your offer to take me among you as a "missionary," but I am grateful to you for the opportunity of testing some of God's gifts that come 'way off from South Africa. I presume likely my Florida home will be the place to test them; but I am so anxious to get hold of the tubers, both amadumbe and sweet potato, that I wish you would send me a very small package here, Medina, and a larger one in time to reach me at my Florida home some time in November; and if you will tell what the postage will be I will remit that also. I should like a good-sized package sent to Florida. I will see

that you get a small "bagful" of dasheens. Your kind offer is one of my "happy surprises," and I am also happy to think that our missionary friends can help reduce "the high cost of living."

GETTING RID OF VERMIN; MOTH-BALLS FOR SQUASH BUGS, ETC.

One of our new poultry-books recommends naphthalene flakes dissolved in kerosene as one of the most efficient remedies for all kinds of vermin about the poultry-house; but although I did not find any naphthalene flakes at either of our Bradentown drugstores, I overheard the proprietor telling the clerk that *moth-balls* owe their virtue to these same flakes. As they cost only 10 cts. per lb., and are so light, you get a big lot in a pound; we use quite a few of them, and they seem to banish all sorts of moth and other insect pests. Now, here is a clipping that indicates a quick and efficient remedy for bugs that infest cucumber and squash vines. I give it to you before trying it, for I feel sure it will do the business, and probably this will hit many of you just about the time the bugs are the worst.

MOTH-BALLS FOR CUCUMBER-BUGS.

Perhaps no reader of *The National Stockman and Farmer* has escaped the depredations of the little striped beetle. Many have become so discouraged by its ravages that they have quit trying to raise melons and "cukes." I have farmed and gardened in several States, and have had all kinds of trouble along this line. Seeds would germinate, plants would start nicely, and just about the time I would think that all danger was past these little pests would descend upon my plants and utter destruction would follow in their wake. I tried every thing I had ever heard of to prevent this destruction, but with only partial results. Soot, ashes, lime, tobacco dust, ammonia, etc., were all given a thorough trial; but never did I find any thing which gave assurance of success until I tried the "moth-balls" or "camphor balls," as they are called. When I plant my "cukes" or melons I place three or four of these balls in and around each hill, pressing them into the ground slightly so that they will not roll around. If these disappear before the vines are past danger I replace them with others until I am certain that all danger is past. Do not allow them to touch the plants while they are young and tender, as they may do some damage. This is a simple, cheap, and effective way to avoid damage from these little striped pests. I have used it for a number of years, and have recommended it to many others, and always with success.

A. L. GEFORD.

Later.—One of the poultry booklets suggests that 2 lbs. of pulverized moth-balls stirred into a gallon of crude carbolic acid, before you use it for painting the nest-boxes, roosting-poles, etc., will make it very much more effective and lasting.

Temperance

"Lord, now indeed I find
Thy power, and thine alone,
Can change the leper's spots
And melt the heart of stone."

Some years ago I mentioned in these pages an address delivered by the mayor of Barnesville, Ohio, before a convention of the Anti-saloon League at Columbus, Ohio. Barnesville was a wet town; and, if I remember correctly, it was very wet, and consequently it was a nest of gamblers. The people, however, put in a good man for mayor, and they were lucky in having a temperance man who was not afraid, and who was about as much a born fighter as some of the gamblers. He undertook to enforce the law and to put the saloons out of business. But some of the wets clubbed together and defied the law. Mayor White had them arrested and fined. But they paid the fine and went at it again. One particularly desperate character locked the doors against the law-enforcement committee and declared that he would shoot any man who would come on his premises. The mayor had him arrested and fined; but he had able counsel, and escaped the clutches of the law, just as we have seen it done in times past. Now, this happened so long ago that I can

not remember all the particulars, but I give what I can remember, subject to correction.

This desperate character put up a sort of saloon barricade made of railroad ties, and he had it ironed off so it required some big stout men with suitable tools to break in and arrest him. I think he passed the drink through a small hole in that barricade, and the money was passed through in the same way. Mayor White sent word to the man that he would have to submit, no matter what it cost. If I am correct, he was once fined \$800 and at another time \$1200. After paying the \$1200 fine he told the mayor if he would let up on imprisonment he would quit the business and go to some other town. He said he had a chance to sell out. The mayor inquired who was the purchaser; and when informed it was another desperate character he refused, and said something like this:

"Mr. DePew, if you will sell your place at a reasonable price to a man who wants to run a grocery on the premises we will let you off."

He accepted the offer, and left the town. He went to Cambridge and carried on the same business for years. Most of our Ohio

friends know something about Cambridge. Well, Mayor White, better known as the Barnesville mayor, gave a talk here under the auspices of the Anti-saloon League two or three weeks ago. Toward the close of his lecture he said something like this:

"My good friends, I have lately received a love-letter that I wish to read to you. I know it is not considered as a general thing good taste to read *love-letters* in public. But as I feel sure the writer will have no objection I take the liberty."

He then briefly narrated what I have mentioned above, and here is the "love-letter:"

Cambridge, Ohio, March 12, 1912.

MR. JAS. A. WHITE, Columbus, Ohio.

Dear Sir and Brother:—Yours of the 8th received, and I must say that I was somewhat surprised to hear from you. Yes, I did join the church, and I think it the grandest thing I have ever done. See here, old pal, I want to say to you that I went into this proposition with my eyes open. I don't intend to try to cheat God's law as I have the State and United States law, as you so well know.

I went into this with the intention of giving up my former business, also gambling, and, in fact, every thing I should not do, and I guess I have done a little of every thing most; but it is not what I have done: it is what I do from now on.

Well, Jim, I can say this much: I don't know of a person in this world toward whom I feel the least bit of spite. That is saying something for me, being the kind of a rounder I was, as I have seen as much of the wicked part as any one of my age. The reward is too great to take a chance. Well, Jim, if I only fight as hard for God as I did for Satan I surely can do some good in this world yet. Well, I hope and pray as I go down the straight and narrow path that I may not vary out of it much. God knows what my outcome will be. I am willing to trust him. He knows I came to him on the square. With best wishes for your success I am

Yours very respectfully,

JOHN E. DEPEW.

Who, do you suppose, wrote that letter? The very man who threatened to shoot the mayor in years gone by, when the mayor's best friends really feared he *would* be shot if he kept on with his determined law enforcement. After the lecture I begged for a copy of the love-letter; and I also asked Bro. White what brought about the conversion of his old friend. He said it was through a series of meetings by evangelist Lyon. Just about that time I noticed in the papers that Mr. Lyon was having a revival at Fairmont, W. Va., where it was reported there were over 2000 conversions. A few days ago I saw another account where the number of conversions in that one town or city had reached quite a little over 3000.*

* Over 2000 converts in one fair-sized town or city! What are we coming to? When we read of grafting, dynamiting, and horrible murders, we sometimes lift our hands in horror and say, "What are we (the world) coming to?" Well, may the Lord be praised for the fact that the world is already coming to something else as well as to wickedness and sin. The world is "coming to" the Lord Jesus Christ, and to repentance and the new birth, like the poor penitent saloon-keeper and gam-

Now, it is not at all likely that Mr. Lyon in his earnest work has *many* such conversions as that of the Cambridge saloon-keeper; but only God knows the number of bad and wicked men who have been changed over—born again. May God be praised for evangelist Lyon, Billy Sunday, Bederwood, and perhaps several others who are now attracting the attention of the whole wide world by their crusade for Jesus Christ. No wonder the brewers and saloon-keepers try to prejudice people against him.

I wish to call attention to the last sentence in that touching letter: "He knows I came to him on the square."

Here is a brief footnote from James A. White in regard to the letter furnished me:

John E. DePew was formerly engaged in the saloon business at Barnesville, O. James A. White was formerly mayor of that city; and, after the saloons were voted out, fined DePew for violating the dry law. The said DePew finally concluded to go to Cambridge, O., and did so, and was arrested there for violating the law; but during the revival services conducted by Rev. Mr. Lyon in the city of Cambridge last winter Mr. DePew was converted and joined the church. Mr. White, hearing of it, wrote him a congratulatory letter and received the above in reply.

May God be praised for such men as the "mayor of Barnesville" as well as for evangelist Lyon. Bro. White told me that for some little time after he heard of DePew's conversion he hesitated about writing to him, fearing that DePew might not feel very friendly toward him, even after he had come out among the converts; and this brought out the letter given above.

ANOTHER TESTIMONIAL FOR "PEACH JUICE."

Our good friend W. J. Bryan's hobby seems to be grape juice, or at least the papers accord him the credit of being the great "grape-juice man." Well, we have good reason to thank God that there is at least one man who stands away up in the affairs of this government who not only *drinks* grape juice but is not ashamed to offer it to the great dignitaries from foreign lands. Well, now for my little story.

Years ago, when Mrs. Root's only sister was a frail little chick lying in her cradle, the doctor feared she would not live long. In fact, I do not know but they had given her up. While the anxious father stood watching her feeble breath, he remembered a peach-tree out in the yard that was loaded with luscious fruit dead ripe, and he wondered if some of that fresh peach juice would not coax back the fluttering breath. He squeezed some of the juice into a teaspoon. She took it with relish, and wanted

bler who wrote that plaintive letter. May God sustain him in his efforts to bless instead of curse humanity.

more; and he fed her on peach juice till she got well and strong. The doctor said he did not *think* it would do her any harm; and as they said they had tried every thing else he did not make any objection. She gradually picked up, and lived to a pretty fair old age. I wonder if peach juice would not be a good thing for babies *now* in place of soothing-syrups and similar concoctions. May be it would be a good thing too for some other folks who are trying to break off from bad habits. Thank the Lord for peaches, and especially for the California *evaporated* peaches of the present day that afford us the means of having delicious "uncooked" peach juice every day in the year.

THE MILLENNIUM COMING—MORE EVIDENCES OF IT.

It is a fine thing to be able to catch a glimpse of the good there is in this world of ours, as well as to recognize and give due attention to the evil that is constantly cropping out. I have been for years past hoping and praying for clean men in the high places of our government. I rejoiced and thanked God when President Taft said, "I do not drink;" and I was glad to hear Roosevelt come out before the world only a few days ago and say, "I neither use tobacco nor drink beer." Of course he gave as a reason that he did not *like* either; but, oh how I did long to have him drop just a word in regard to the example that our presidents and other men in high places set before the boys—especially the little boys in this land of ours. I rejoiced and thanked God when Secretary Bryan passed around the "grape juice" to the foreign dignitaries, and gave his reasons for so doing. I rejoiced again when our good President not only indorsed Bryan but banished liquors from the White House. My last rejoicing was when I read the following clipping from the *Cleveland Plain Dealer* in regard to Vice-president Marshall:

HAS HOE-CAKE AND MILK; VICE-PRESIDENT MARSHALL BELIEVES IN SIMPLE DIET.

A slice of old-fashioned "hoe-cake" and a generous glass of creamy milk is the lunch upon which Vice-president Marshall subsists 365 days of the year.

The Vice-president has a theory that a simple diet is a builder of happiness. Recently he said in a private conversation that the United States would be a nation of happy men and women if a less complicated diet came into fashion.

"It is not that Americans are gluttons," he said, "but they want an infinite variety in their food. The American palate has lost its taste for the plain cooking of our forefathers, and longs for French messes."

Amen to Bro. Marshall's timely rebuke to the women who spend their lives and take so much pains in tempting us men folks to eat more than is good for us. May God hasten the day when more of us can make

out at least one meal out of the three with hoe-cake and milk. Now, will some good friend who sees this tell me where Bro. Marshall gets his hoe-cake? Can it be bought at the bakeries, or must it be baked on a hoe? In other words, what is this hoe-cake that Vice-president Marshall eats at least once every day in the year? We can get a glass of "creamy milk"—or at least most of us can—without very much trouble, thanks to the recent fashion of drinking milk instead of beer. Now give us the hoe-cake, or tell us where we can get it "pure and unadulterated."

SPELLING "CIGARET."

'Tis only a word, but one you've oft heard;
We call it a cigaret;
I'll spell it, so that, hearing, you'll know,
And, knowing, you will not forget.

There's C for the cad it makes of the lad
Who twirls in his fingers the bit
Of a paper rolled up (a tobacco-filled cup),
And thinks he's a man when it's lit.

Then I is for imprints of stains;
And the dark hints of shadows lie under his eyes;
For once he starts smoking it comes far from joking—
It's leading to swearing and lies.

G is for gladness cigarets turn to sadness
When once they have gotten their grip;
Their kisses leave trains of yellow dark stains—
To remind him on fingers and lip.

Allurements for A—temptations so gay
Beckon with jewels and wine;
He finds out at last that it may be all brass
As well as the gold that will shine.

Then reckless for R, and the reason they mar
The rugged good health he has lost;
"Oh, why? and oh, why?" says the lad with a sigh,
"Did I never quite reckon the cost?"

E is for ease, and the "do as you please,"
The attitude bold he assumes;
He's getting more lazy, his mind is more hazy,
The more "coffin-nails" he consumes.

Next T is for times he has wasted his dimes
On parcels of paper and weeds;
Oh! little he thought, when the first one he bought,
That trouble was planting the seeds.

So now you may see what the small word can be
When each of its letters you spell;
It's letters are few, 'tis a small word, 'tis true,
Till some of its meanings you tell.

Gladwin, Mich.

MRS. HUBER SOPER.

ANOTHER KIND WORD FOR TERRY'S BOOK.

I enclose \$1.50 for GLEANINGS and Terry's book, "How to Keep Well and Live Long." I have already had two. One I gave to a friend who liked it so well *she* gave it to a friend and bought one for herself. The other I have not seen since last June. It has been lent so much I have lost track of it, and do not expect to see it again; but I want one for myself. I expect to take GLEANINGS as long as I live and can see to read, or as long as A. I. Root writes for it, or Dr. Miller. EVA M. CLEVELAND,
East Cleveland, Ohio, April 14.

Health Notes

POSTUM CEREAL, WHEAT COFFEE, AND SOME OTHER THINGS.

Years ago I became satisfied that coffee was injurious. I tested it repeatedly on myself, and watched its effects upon others; and when I noticed how the habit seemed to be growing, and saw statistics in regard to the amount of money paid for coffee, not only throughout the United States but perhaps almost all over the world, and oftentimes paid by poor people who had hard work to make ends meet, it seemed to me a very sad condition of affairs. As the years passed, and I saw the habit of drinking coffee growing instead of lessening, I wondered if any thing could be done to stop it. Now, in view of the above it seemed almost funny—yes, I might almost say a big joke—to find a man who has gotten rich—yes, become a millionaire, and, for all I know, a multi-millionaire—protesting and teaching and *preaching* about the harmfulness of coffee! I remember Post when he first started out with his postum cereal and grapenuts. In fact, I was one of the first to get his substitute for coffee and give it a pretty good test to see how much truth there was in his claims; and I have smiled and felt happy as the years have gone by to see what a tremendous business he has been building up in getting people to give up things that are hurtful and harmful. Very likely there is some exaggeration in the letters he has published; but notwithstanding I believe that Post has been one of the great reformers of the age; in fact, he has been doing a great missionary work in his own way, and getting big pay for it.

You might imagine from what I have said above that Post has given me "*big pay*" for writing up his products, and you might expect that a big glaring advertisement might come out in GLEANINGS very soon. I want to tell you, my good friends, that Post, for some reason or other, has never seen fit to patronize GLEANINGS by giving us even a single line of his advertising. Perhaps if somebody should call his attention to the above he might send us a "good slice" of his advertising business—that is, if he didn't read further and see what I am now going to say. Notwithstanding I honestly believe all the above is true, at the same time I want to call the attention of our readers to the fact that it is a tremendous waste of money to buy postum cereal instead of making the wheat coffee that our good friend Terry has advised and directed how to do so many times in the two or three years that have passed.

Grapenuts has proved a very good and agreeable food in our home. We have used it more or less ever since Post gave it to the world. I think he has done good with the grapenuts as well as the postum cereal, even if he has had big pay for his missionary efforts. If he would only come down on his prices to half, or a good deal less than half, he might still make money and do good. I think I am safe in saying this, for I believe that Terry's wheat coffee is every bit as wholesome and good as the postum cereal. I am all the while getting so many letters in regard to wheat coffee, and so many inquiries, I think I can tell you best all I know about it by giving an extract from a recent number of *The Practical Farmer*. Here it is:

A CHEAP, WHOLESOME BREAKFAST DRINK.

Our women readers can save quite a little money by following advice given here. And that means more money for other comforts. There is a continual call for directions for making our wheat "coffee." So we give them again. I have just roasted enough at one time to last several months. I use plump re-cleaned wheat, same as we grind for graham flour. Make a hot fire in the cook stove or range. Roast in iron dripping-pans, the wheat about one inch deep. Fill the oven full. When the wheat gets dry and hot you will need to stir it with a large iron spoon once a minute, more or less, to prevent its burning. It should be roasted very brown, but not burned away, if you can possibly avoid it. Smoke indicates that it is burning. I bought extra dripping-pans so I could roast considerable at once. They cost but little. One should put an even number of pints of wheat in each pan, say two or three, no fractions, for convenience when adding molasses. When the wheat is thoroughly roasted add 3 tablespoonfuls of New Orleans molasses to each quart of wheat. Then roast 10 or 15 minutes longer, but with less fire, as it burns easier after the molasses is put in. When done, empty each dripping-pan into a large pan that will hold all you have. Stir and mash with a large spoon to prevent its caking as it cools. One is not likely to get every painful roasted the same, and this mixing makes the quality even. We used to put in butter to prevent its sticking together; but this stirring as it cools answers as well, and the wheat keeps better. When cold, seal up in glass fruit-jars and store where it is dark and cool. Grind each morning fresh, and boil about 20 minutes. Two teaspoonfuls make four cups as strong as we like. You will soon like it as well as any coffee, and it is free from poison. Let the children have it. If it is not as dark-colored as coffee, and good flavor, you did not roast it enough. Of course, you can buy a cereal drink in paper boxes at a cost of 10 to 20 cents a pound, but we do not think any of them as good as ours, which costs about 3 cents. We do not tire of it, year after year. I really like it as well as cereal coffee—quite a little money saved.

Now, after you have read the above I want to tell you that our next-door neighbor, a Mr. Ault, who has just come from Colorado and settled down here in Florida (a beekeeper, too, of no small experience), has brought along with him some very nice

plump Colorado wheat—about fifty bushels. As soon as we Florida folks found it was for sale, and also that it was so much nicer than any we get in our market here for the chickens, we very soon relieved him of all he had to sell. Well, now we have taken some of this wheat and ground it in that little hand mill that I described so many times, and we have the most luscious graham bread that I ever ate in my life. And after the flour is sifted out for the graham, Mrs. Root boils the coarser wheat three or four hours, or all the forenoon. Now, this wheat mush, when it becomes cold, is sliced up and put into the oven just before breakfast or dinner until it is nicely warmed up and a sort of jelly formed over the outside. A slice of this nice wheat mush, nicely buttered over, is the finest cereal of any thing I have ever tasted in my life. If you want to get a dish that is fit for a king, as Ernest expresses it, add a little honey after it is well buttered. I do not very often use the honey, because I have to be a little careful about too much sweet of any kind. Right beside your plate you want a glass of rich milk. Take a sip of the milk as you chew the wheat thoroughly—mush and milk literally. I want to add that we have the finest milk down here in Florida that we ever had in our lives, from neighbor Rood's Jersey cows, and he does not have to *buy hay* either. He grows every bit of the hay he uses for his horses and cattle on his own place. We have just one pint of this Jersey milk a day (and it is a good *generous* pint), but this milk not only furnishes all the milk we use, but Mrs. Root skims off the cream and often makes quite a little butter, and this cream she gets into butter in less than five minutes.

THE PATENT-MEDICINE BUSINESS; THE STAND SEARS, ROEBUCK & CO. HAVE TAKEN.

We clip the following from a leaflet just sent us:

WHY WE HAVE DISCONTINUED PATENT MEDICINES.

Many of our customers will be surprised and possibly some of them disappointed, to find that this catalog no longer lists the various patent medicines we have carried in the past. Our decision to discontinue the sale of patent medicines was made after careful study of the question from all sides, and is based on our policy of handling only dependable merchandise—merchandise that we believe will give the service our customers have a right to expect. We have come to believe that patent medicines do not conform to this standard; in fact, we are confident that those of our customers who have investigated the matter thoroughly will agree with us that, considered in all its phases, the patent-medicine business is a public evil.

We are not prepared to take the extreme position that no medicines of any kind, regardless of how simple or in what manner advertised, should be offered direct to the public. However, even such a

state of things might easily be better than the present situation, in which we find valueless and even dangerous medicines offered to the public through the medium of advertising that is extravagant, misleading, and deceptive—advertising calculated to deceive the well into the belief that they are sick, and to induce the sick to pin their faith to ineffectual means for recovery.

Practically every patent medicine is put out under a trade-mark name and secret formula. The fact that the name is private property makes advertising profitable where otherwise it would not be. Secrecy permits advertisement of the most extravagant sort to go more or less unchallenged. It is not unusual to find a patent-medicine advertisement that tends to leave the impression that there is a "mysterious something" about the medicine that is sufficient to account for the otherwise unbelievable virtues attributed to it. In selling patent medicines the tendency is to tell as little about their composition and to claim as much for them as the law will allow.

That patent medicines are more than likely to be disappointing as well as dangerous is apparent when we consider the fact that the all-important as well as the most difficult thing in the treatment of disease is that of finding the real underlying cause of the trouble, and the further fact that the person least able to form a safe judgment in this matter is the patient himself.

The person who falls a victim to the advertisement that attaches a grave meaning to every little ache or pain, when in reality nothing ails him that forgetting would not cure, is at least defrauded.

The person who depends on an advertised nostrum to cure a serious ailment which, to be successfully treated, must have only the most prompt and skillful attention, is throwing away valuable time. The most dangerous medicine, especially in the case of the lingering disease that drugs alone can not cure, is that which, by containing a stimulant or an opiate, causes its victim to feel better for a while. Being thus encouraged in a vain hope, though all this time the lurking disease is steadily progressing, he often turns too late, if he turns at all, to rational means for recovery.

INSANITY AND ITS RELATION TO INTEMPERANCE.

We clip the following from the *Sunday School Times* for June 7:

WHY INSANITY DISAPPEARED.

In ninety-seven of the counties of Kansas there are no insane, in eight-five counties no feeble-minded, in fifty-seven no paupers. It can not be accident that has sent the germ plasma of insanity skipping out of Kansas. It is obviously and unmistakably due to the enforcement of prohibition and the consequent decrease of the neuropathic taint.—DR. MARY WOLFE, University of Michigan, in *Philadelphia North American*.

My friends, how are insanity, feeble-mindedness, and pauperism in your county? I am ashamed to say that our own county of Medina, here in Ohio, is nowhere near what is reported above in "prohibition Kansas." How is it possible for any sane man or woman to vote wet when wet votes mean, *without question*, insanity, feeble-mindedness, and pauperism?

The A. I. Root Co.:—Please discontinue my ad. as I no longer can care for orders.

MORE BEES KILLED BY SPRAYING WHILE IN BLOOM.

THE following from a correspondent is one of many more reports that we have received showing the injurious effect upon bees of trees sprayed when in bloom. While the quotation here given does not state this fact exactly, yet we know the bees would not have been killed unless the trees were sprayed while in blossom. Here is the item:

Bees have been killed by the peck in this locality by spraying with arsenate of lead, and it looks now as if little or no comb honey will be secured this season. C. E. PALMER.

Ransomville, N. Y., June 13.

CONNECTICUT PASSES A FOUL-BROOD LAW.

WE have just received a copy of the foul-brood law recently enacted in Connecticut. It is an excellent law, and it seems to be very carefully worded throughout. However, it limits the amount that may be expended for carrying the act into effect to \$750. Of course, Connecticut is a small State; but to do effective work the appropriation certainly ought to have been larger. But doubtless the beekeepers of Connecticut are very happy to secure as much as they did, especially as the general provisions of the law are excellent. The way is now open to secure a larger appropriation later if necessary.

THE CANADIAN BEE JOURNAL ABSORBED BY THE CANADIAN HORTICULTURIST.

IN June the *Canadian Bee Journal* and *Canadian Horticulturist* were consolidated, or, rather, the *Canadian Horticulturist* purchased the *Canadian Bee Journal*, and it now has a large department entitled "The Beekeeper." This department in the first issue since consolidation is well illustrated, and the matter carefully selected. Doubtless the *Canadian Horticulturist* recognizes the intimate relation between the two lines of industry, and the combination is most natural. As the *Canadian Horticulturist* is an old and well-established journal, it is doubtless true that the beekeeping interests on the other side of the line will be taken

care of as well as or better than was the case when the publication was devoted wholly to bees. GLEANINGS offers its congratulations and best wishes.

DEATH OF WILLIAM M'EVROY.

JUST as we go to press, announcement has reached us of the death of our old friend Wm. McEvoy, of Woodburn, Ont., Canada. Mr. McEvoy was one of the pioneers in the treatment of foul brood; indeed, he was the author of what is known as the McEvoy treatment of foul brood. This did not differ materially from the Quinby or the Jones methods except that he gave two shakings on two sets of foundation, and put the bees back in their hive.

Wm. McEvoy was a prominent figure in Canadian beedom. He was for years its only foul-brood inspector.

"Mac," as he was familiarly called, was a "hail fellow well met." The position of any foul-brood inspector is sometimes embarrassing in that he sometimes has to deal with people who are inclined to give him a sort of shotgun reception. "Mac's ever ready Irish blarney" (in the language of J. B. Hall) was at all times equal to the occasion. He always knew how to handle his man, and before leaving he would get his good will.

Mr. McEvoy was a large producer of honey, a good beekeeper, and his death will be regretted by his many friends.

It used to be said that a convention in Canada would not be quite complete without J. B. Hall, of Woodstock, Ontario, or Mr. McEvoy, of Woodburn. Both of them had a happy faculty for enlivening discussions and for throwing in practical suggestions. Both together made a team. But both have gone to the land beyond.

In later years the problem of taking care of foul brood in Ontario became too great for one man to handle. Our friend Mac believed he could handle it all; but in that he was mistaken, for the disease was surely getting the better of him. In later years it was discovered that even five or six men could hardly cope with it. During the last

four or five years Canada has had, we believe, five or six inspectors.

Our old friend took it to heart when the beekeepers of Ontario decided that they needed six inspectors in order that the whole territory might be thoroughly and completely covered. In the last year or so he dropped out of the inspection work, and devoted his time wholly to the production of honey. Peace to his memory.

HONEY PRODUCTION AT MEDINA.

THE past few days have been very busy ones at the Medina apiaries. The 1000-lb. automobile truck has been kept busy going to the yards and bringing in honey and bees. A part of one day and a part of another we took off 9000 lbs. of extracted from a part of the home yard and one out-yard, and we have an extraing to take at both yards yet.

THE STEAM UNCAPPING-KNIFE.

We have been trying out the steam uncapping-knife and the ordinary knives dipped in hot water. When there is a large amount of uncapping to do, especially if the capping extends clear over both surfaces of the comb, and the honey is thick, the steam-heated knife is far ahead of the ordinary knife dipped in hot water. But when the cappings cover only a part of the surface, the hot-water-heated knife does practically as well as the steam-heated knife, and avoids the inconvenience of the tubing reaching from the boiler to the knife.

THE CANADIAN UNCAPPING-KNIFE.

We have also been testing out the Canadian form of knife as compared with the Bingham. At first the boys were inclined to favor the former; but after a more thorough testing they decided that the Bingham shape is the better, as it takes less pull on the wrist to shove the Bingham through the cappings, for the reason there is less beveled edge to cause friction on the comb.

THE PETERSON CAPPING-MELTER.

We have been using with considerable satisfaction the Peterson capping-melter; and when the big power extractor was throwing out the honey faster than one man could uncap, another man was put on the other side of the machine. The honey and wax flow together into a wax-separator; and the honey from such separator, so far as we can discover, is equal in flavor to that taken with the regular honey-extractor. At the end of the day's work there are no cappings lying around, for the reason that they have all been melted and the honey separated out. More or less dirt from old combs will run in with the wax. The big cake of wax from the separator is taken out, re-

melted, clarified, and recaked before it is fit for the market.

THE HONEY-PUMP AND THE GRAVITY SETTLING TANK.

The honey-pump continues to do good work. It carries the honey to any point desired into an elevated gravity tank. All dirt, skimmings, dead bees, etc., rise to the surface. The honey is then drawn off into square cans from the bottom of the tank. We have no hesitation in deciding for the gravity scheme for clarifying honey rather than fuss with honeystrainers that are continually clogging up.

ELECTRIC ALARM FOR FILLING SQUARE CANS.

We have been using an automatic electric alarm to give notice when the 60-lb. cans are full. The whole thing can be made in about an hour, and is so simple that any one can make it. A full description with illustrations will appear later. Of course, the idea is not new; but the manner in which we have applied the principle may be new to some.

THE AUTOMOBILE TRUCK FOR BEEYARD WORK.

The automobile truck (the Commerce) is doing splendid service. It has never given us any trouble except once when we got stuck in a mudhole through the inexcusable negligence of certain township trustees who allowed the place in question to become impassable for even horse-drawn vehicles. Otherwise our truck has responded promptly through mud and rain, day in and day out. It has enabled one crew of three men to take care of five queen-rearing outyards, including the one home yard. Our foreman has set his stake at 100 lbs. per colony, spring count. If the drouth had not set in so severely he would have reached his goal, and he may do it as it is. Nor has the basswood apiary, in charge of our Mr. Pritchard and his son, been idle. This yard will turn out about 3000 queens besides its full quota of honey.

CRANBERRY-GROWING ON CAPE COD, MASS.; A REMARKABLE INSTANCE SHOWING THE VALUE OF BEES AS POLLINATORS.

JUST before we started for the Massachusetts convention referred to in our July 1st issue, p. 434, we received a letter from the President of the United Cape Cod Cranberry Co., Mr. Marcus L. Urann, at South Hanson, near Boston, inviting us to look over their cranberry properties where they are conducting some experiments with bees in pollinating the cranberry-blossoms. After the convention we went on to Boston, then on to South Hanson, where we met Mr. Urann.

The United Cape Cod Cranberry Co. has

discovered that the yield per acre could be enormously increased by having bees within convenient access. Formerly wild bees in the locality have been sufficient to do the work of pollination for the cranberries; but the experimental department of the United Company believed that there was not at all times a proper pollination, and in looking about for ways to improve and increase the crop, it was determined to increase the number of bees. The company began to buy up bees and put them at the various properties, when, presto! the yield came up. The company has now something like 700 acres of cranberries; and in the near future it will increase this acreage to 2000. It is in no way interested in the production of honey only as the honey itself may be used as a means for paying for the bees, and perhaps leave a comfortable margin besides. What the company wants is cranberries, honey being only a secondary consideration. So gratifying have been the results by increasing the number of bees that Mr. Urann has employed a beekeeper to make rapid increase so that he may be able to take care of their various properties by having the requisite number of bees at each bog where the cranberries are grown.

The problem that Mr. Urann would naturally like to solve is, just how many colonies of bees are needed for a given acreage; and when he put that proposition to us we admitted that we might be wild in our guess.

One test was, however, somewhat significant. There was one bog at Halifax that had 126 acres of cranberries. On one side of this were some three or four colonies last year. It was very evident that this number was inadequate to cover the entire field. It was very significant that the yield per acre of berries was in direct proportion to the proximity of such acreage to the bees. The yield was heaviest close to the hives, and was thinner and thinner as the distance from the hives increased. The showing was so remarkable in this and other fields that Mr. Urann proposes to increase materially their investment in bees another year.

In a small way he has conducted some experiments where he screened a small area of cranberries away from the bees, and right beside it he established a small plot that the bees could visit. There was a "deadly parallel" between the two. The screened portion had very little fruit, while that free to the visitation of the bees had a large yield. We will not attempt to give the actual figures at this time. This whole proposition is so interesting that we are now laying our plans to make a second visit to see those wonderful establishments

where the bees are proving to be such benefactors, not in honey production, but in the enormous increase of the yield of berries per acre.

In our travels over the United States we never saw a situation that demonstrated more clearly the value of bees as pollinators than in the cranberry-fields. Every cranberry-grower is now making plans to go into the bee business, not because he expects to produce honey, but because he knows by putting in bees he will increase his yield of cranberries per acre.

We might explain that a cranberry-bog is nothing more nor less than a piece of swamp land carefully and accurately graded after all trees and other vegetation have been removed. The cranberry-plants spread and grow like strawberry-vines, and, like the strawberry, they must have bees.

At some future time we hope to present some photos that will show some of these remarkable fields where the bees are earning more money for their owners than probably any other bees devoted to the production of honey anywhere in the United States.

HONEY-CROP CONDITIONS.

REPORTS from supply dealers and beekeepers generally go to show that 1913 will go down in history as a great clover year. There has been a tremendous yield in many localities; but in others the drouth has been so severe that the crop has been cut short or cut off entirely. But the yield has been so heavy in favored localities that white-clover honey will be very much in evidence in the markets. It is of very fine quality, for the reason that weather conditions were ideal for ripening. In general, reports indicate that this has been an off year for basswood. Late reports from some parts of Ontario, Canada, indicate a big yield from clover. In some parts the yield was cut down by early frosts.

Had it not been for the drouth setting in, in many localities, the honey markets of the East, at least, would take a tumble. As it is, prices will probably rule easier than last year. However, it is rather early yet to make a definite statement as to what the actual clover crop will be. Reports have not come in very numerously as yet; but here are a few that will give some idea of what the season has been. It should be noticed that the reports up to June 28, from some localities, are discouraging on account of drouth. But in many of those drouth-stricken places heavy soaking rains have since come, with the result that honey began to come. This was particularly the case in New York. Well, here are a few of

the reports from the clover districts, and one or two from the West:

The honey crop is almost a failure in the black belt of Alabama. It will be the shortest crop we have had since 1907. We have abundant clover, but the weather is so dry it does not yield much honey.
Montgomery, Ala. J. M. CUTTS.

The honey crop in this section will be almost a total failure this year.

Watsonville, Cal., June 27. C. W. ARNETT.

I never saw so much white clover, even in Ohio. Ingleside, Ill., June 25. D. B. STANFORTH.

Prospects are good for honey; plenty of white clover.

Freeport, Ill., July 1. A. E. LONG.

The honey-flow here unusually good. White clover is abundant.

Chesterfield, Ind., June 26. J. H. COLLINS.

We expected a bumper crop of white-clover honey, but drouth knocked us out. No rain for three weeks caused white clover to dry up.

Vincennes, Ind., June 23. WM. F. LUDWIG.

Bees are breaking all records so far this year—the best honey-flow in 30 years up to July 5. I have taken off over 100 lbs. per colony of comb and extracted honey, and it is the finest I have ever produced.

Chariton, Iowa, July 5. L. RIEBEL.

Bees have done better than usual this season; also made more trouble by swarming. Basswood will bloom in a few days, but the bloom will not equal last year. The two months' drouth was ended the past few days with showers, making 2.25 inches of rain.

Payson, Ill., June 26. DANIEL E. ROBBINS.

Our June flow is at least 25 per cent above the average. The yield from white and sweet clover is very good. Basswood is blooming sparingly.

North Tokepa, Kan., June 24. A. V. SMALL.

Bees are strong, and doing excellent work. Clover is yielding an abundance of nectar; good crop expected.

Brooksville, Ky., June 26. H. C. LEE.

Honey yield is a record breaker. White-clover honey had to be removed by June 26 to make room for basswood. Basswood rich in bloom and honey; bees having nine more days to work. It will be in all a double crop or better. After the rains white clover is very thick again.

FRANCIS JAGER.

St. Bonifacius, Minn., July 7.

Our honey crop is very short in this part of the country on account of dry weather.

Strafford, Mo., June 30. L. A. WEBSTER.

The prospects are fine for a good crop of honey in Nevada this year.

Smith, Nev., July 2. C. M. CARTER.

There has been very little honey gathered from clover to date. Fruit bloom was very light, and the prospects for a good crop of honey this year are discouraging. We have had a dry cold June.

Pittsfield, N. H., June 27. HERBERT C. TOWLE.

Crop of clover honey a failure here. I have run four yards of bees, and have not had a swarm so far this season. Too dry.

Parkville, N. Y., July 8. A. W. SMITH.

Reports we are receiving say, "Hives are over-running with honey." The weather is still good for honey, and beekeepers are mostly jubilant. I hope it will continue so till August 1. Then look out for a bumper crop.

F. A. SALISBURY.

Syracuse, N. Y., July 1.

Clover is a failure—worst in 20 years. Basswood is ruined by forest worms, etc., except scattered spots.
R. G. SMITH.

Ticonderoga, N. Y., June 25.

At yesterday's meeting the New Jersey Beekeepers' Association reports indicate general conditions as unsatisfactory—from half a crop to a total failure, attributed mostly to alternating heat and cold, especially cold nights, which seem to check nectar secretion. White clover is in great abundance, but little or no "juice" in it. This condition seems general.

Hoboken, N. J., June 26. C. D. CHENEY.

This has been about the best clover flow we ever had; but it is practically over, as the buds on the basswood were killed by the cold spring. We shall get no basswood honey.

Hastings, Ontario, July 5. J. F. ORISHAW.

The spring freezes of April 20 and May 6 paralyzed honey production, and nearly ended the bee business with me; yet the clovers have finally turned the scales, and I am now selling honey again. My production will be below normal, and will likely not exceed 1000 lbs. of comb honey.

Bladen, O., July 7. CHAS. H. CARGO.

There is the largest crop of white clover there has been for many years.

Bulger, Pa., June 30. M. M. PHEEN.

I report about half a crop, all alsike and white clover. Locust, not any. Red clover, hardly any here.

Ronks, Pa., June 25. D. F. ZOOK.

Bees are booming; clover bloom is the finest in years; supers filling up rapidly; very little swarming.

Wilksburg, Pa., June 25. W. D. KEYES.

A severe drouth will prevent our getting a large crop of honey.

Middlebury, Vt., June 28. J. E. CRANE.

The clover looks well here, and the bees that had stimulative feeding enough to build up strong are doing well, and there will be a good crop of honey here.

Albany, Vt., June 27. J. M. CARTER.

Bees are not doing what they ought to. There is the most clover in blossom at present that there has been since 1893. Weather for a few days has been clear and hot. A good swarm on scales, with an empty extracting-super, gained 4 lbs. on the 27th; $\frac{3}{4}$ the 28th.

Stockbridge, Wis., June 29. ANDREW STEVENS.

There have been almost no reports from the irrigated alfalfa districts. However, there is nothing to indicate that the season has been below normal. In California the season has been reported as a failure; but the *Western Beekeeper* for July 1 has this from A. S. Wagner, of Imperial Co.:

In GLEANINGS IN BEE CULTURE, page 327, this notice appeared: "California honey crop a failure." I consider this misleading. This fact should be stated, "that certain crops were a failure." It would seem from that article that orange and sage honey were the only crops produced. Hereafter the alfalfa honey will be quite a factor in the honey shipped from this State. I am not familiar with the central and northern portion of the State; but Imperial County alone should normally produce from thirty to forty carloads of honey per year. This is not intended for a booster, but we feel that the public, and the buyers especially, are entitled to be informed of this fact.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

J. E. CRANE, p. 402, while you're about it you may as well have wire cloth with mesh just small enough so that a bee can't get through. That would be a shade less than 1-6, which would obstruct the vision about three-fourths as much as $\frac{1}{8}$ mesh.

JUNE 30 the average number of sections over each colony was 103.04, and 15.36 had already been taken off. Of course, part of those on the hives—perhaps one-fourth—were empty sections; but even so, no such story could ever be told in June before. Certainly I never knew such a flow before. One factor in the case is the alsike, which is increasing wonderfully, springing up on the roadside and other places where one would suppose no seed could have fallen.

POLLEN in sections is spoken of as a matter of location, p. 388. Isn't it rather a matter of shallow brood-combs? [Yes, the depth of the brood-chamber will have a great deal to do with the absence or presence of pollen in the supers; but is it not true that there are other factors? For example, if there are no outside brood-combs in the brood-nest in which pollen may be stored, and the rest of the brood-nest filled with brood and honey, the bees are more inclined to store pollen in the sections. They must put it somewhere. The advice has often been given to see that there be empty comb in the brood-nest next to the hive walls to catch pollen. Some of the users of shallow brood-chambers have stated that this is an absolute remedy.—Ed.]

ARTHUR C. MILLER, what you going to be up to next? The cheek it must take to tell us, p. 370, that not only may a queen be successfully introduced within an hour or so after the removal of a laying queen, but that virgins or laying workers are no hindrance. Well, there ought to be enough try it before the summer is over to know how it works. But, say; you talk about bees tolerating a plurality of virgins. You hardly mean that more than one virgin will be out of the cells, do you? Any way, it's not a question of the bees tolerating virgins, is it? Isn't it the virgins that won't tolerate one another? I suppose in one sense it might be said the bees tolerate a plurality of virgins in their cells when they stand guard over them to defend them against their murderous elder sister.

A SUNDAY-SCHOOL field-worker of Illinois surprised me by saying he thought cigarettes worse than whisky. I'm slowly coming to believe he's right. I'm pretty sure

little boys in Marengo are in greater danger of becoming users of cigarettes than users of whisky or beer. Even if the cigarette does only half as much harm as drink to its victim, if it catches three times as many victims it is the greater curse. And I'm not sure that the cigarette is at all behind drink in destroying the physical and moral stamina of a boy. I don't know how it is elsewhere; but here the cigarette seems to get hold of boys at an earlier age than drink. Somehow boys can hide cigarettes from their parents longer than drink. If the cigarette curse increases in the next ten years as it has in the past ten, we're going to be a nation of imbeciles.

AN unsupplied want is a set of grader's balances for grading honey. We have scales galore for getting the weight of honey, but we don't want to know how much a given section weighs. Take the Colorado rules. There are just two questions to which the grader may want an answer: "Does that section weigh 'less than 13½ ounces'?" or, "Does it weigh 'less than 12 ounces'?" The exact weight he cares nothing about. So he wants two balances, one having on one side of it a weight of 13½ ounces, and the other having a weight of 12 ounces. Then if the section goes down it goes, and if it doesn't go down it doesn't go. And these two balances should cost a good deal less than any single weighing machine. H. H. Root, here's a chance for your inventive genius. [A pair of balances might be made to take two different weights, as you indicate; but they would cost more than regular scales; and is it not true that it is more practicable to make three or more gradings as to weight if there is any difference?—Ed.]

"BEES can build comb in confinement, but it is a very unusual procedure," p. 388. I wonder if it is. The first package of bees I got from Medina last year had built about two square inches of comb. [Perhaps we put it too strongly. If so, we are subject to correction. Some 25 years ago Mr. Paul L. Viallon, of Bayou Goula, La., who was then quite active with bees, reported that it was with difficulty that bees could be made to build comb in confinement; but when they could fly out every day they would build it much more readily and with less stores. He was testing out the truth of the oft-repeated statement that it takes 20 lbs. of honey to make 1 lb. of wax. He found that it would take about that amount if the bees were confined; but if they had

their liberty it would take a great deal less. His figures were between six and seven pounds. Just how he could take account of the nectar brought in and converted into wax, we do not now recall. Perhaps some one has definite figures that will bear on this question.—Ed.]

THE *Vindicator*, a Prohibition paper, has a "vision" of all the opponents of the liquor-traffic getting together as one body in the more or less "near future," based on the idea that the Anti-saloon League meditates constitutional prohibition for the whole country. It thinks that will necessitate separation from all parties not committed against the saloon, and that Anti-saloonists and Prohibitionists will unite as one party. That "vision" may or may not be an idle dream; it seems unthinkable that the enemies of the saloon shall go on for ever making faces at each other in two separate camps. As a consistent Prohibitionist, lo! these many years, I'm ready to vote that, if the great body of Anti-saloonists can make good use of the machinery of the little Prohibition party, they can have it at a bargain; or if the Anti-saloonists organize a political party of their own, I vote to scrap the machinery of the Prohibition party, and crawl under the canvas to get into the tent of the new party.

JUNE 11 I saw something new to me. Bees were bunched on the front of No. 54 as if it might have recently swarmed and returned. My assistant opened the hive to look for the queen, leaning the super, which was very full of bees, against an adjoining hive. Happening near I saw the bees beginning to leave the super, not in the ordinary way, but pouring out like a swarm. I said, "The queen has gone up into the super, and that has induced the bees to swarm out of it." So I began to look on the ground for the clipped queen; but my assistant continued her search in the hive. Presently she said, "You needn't look any longer for the queen; here she is in the hive." Sure enough, there she was. The bees sailed around a while like any other swarm, and then returned, not to the super, but to the regular hive-entrance. All this while the bees in the hive were quiet. Now, what did it all mean? Had those bees in the super failed to swarm out with the bees in the hive and then decided to swarm on their own account afterward, or how was it? Don't tell me those bees were not swarming. There's a lot of things I don't know about bees; but I know a swarm when I see it is issuing, and I know that was a swarm. [There are some things about the causes that induce a swarm to light out that

we do not understand. Years ago we heard a zeep, zep, zeep, in front of the entrance. Presently the queen came out, and then with her the bees. At other times the bees apparently take the initiative and the queen follows. When this takes place, some sort of signal or commotion is needed to start things going. Apparently this signal, or whatever it was, was given in that super, and apparently, too, that signal was not communicated to the brood-nest. This is a place where most of us will have to say, "I don't know." If any one does know what the exact procedure is that induces a swarm to hike out suddenly from the hive, let him tell us.—Ed.]

J. L. BYER, you ask, p. 439, whether in five weeks bees will scoop out enough of a winter nest to accommodate even one quarter of the bees. I don't know. I doubt if they will. Yet even that small space is enough for that editor to claim that they have a brood-nest. But let me say something that I do know. I know that empty cells—in other words a brood-nest—are not needed for all the bees. In winter I see a big cluster of bees hanging below the bottom-bars in some of my colonies; and the bigger the cluster the better it looks to me. Below the bottom-bars is surely outside the brood-nest. Now if those bees—possibly a third or more of the colony—can winter all right outside of any brood-nest, you ask that editor why it isn't possible for the rest of the colony to do the same thing. [Doctor, you are confusing the issue. You are talking about indoor wintering. It is perfectly practical for bees to cluster below the frames when they are in the cellar; but did you ever know of a case of their doing so when the hives were outdoors in cold weather? We have contended that a small winter nest below the honey is important in getting good results in outdoor wintering. This winter nest will gradually enlarge.

It is hard for us to believe that solid combs of honey—combs an inch thick, dividing up a cluster of bees when wintered outdoors, is an ideal condition. A colony that is wintering nicely outdoors has a winter nest. The bees are thickly crowded in the cells, and the only separation is the walls themselves and the midrib on the combs. Such a condition is natural, and allows the heat to be communicated from bee to bee, while solid slabs of honey an inch thick act as a non-conductor, breaking the cluster up into a series of thin slabs.

In talking about this winter nest, do not confuse outdoor and indoor wintering—Ed.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

Bees have been greatly reduced in strength here in Vermont for lack of stores this spring. Consequently queens have stopped laying, or at least brood-rearing has been checked, so the force of workers for gathering the harvest of nectar when it comes will be small compared with what it would have been if there had been a good supply of honey in the hives, or if the weather had been such that the bees could have gathered any outside of their hives.

* * *

The spring here in northern New England was peculiar. It was warm in April, while May was very cold, and it continued cool up to June 15. Nearly all fruit except in favored places was ruined. The bees were strong May 1, but by June 1 about half were in a starving condition unless they had been fed. Very few yards have been fed as much as they needed, and so we have a shortage of brood. Where only a few colonies are in one yard they have done much better. This shows very conclusively that in the cool weather of spring bees go only a short distance from their hives, and a few will thrive where a large number will starve, while in warm summer weather a large number will do nearly as well as a few colonies in a yard.

* * *

I believe the most valuable article in the issue of GLEANINGS for March 15 is the editorial by A. I. Root under Our Homes. The subject is one that fathers and mothers find it difficult to talk to their children about, and yet a most important one. I believe those somewhat along in years can see the evils to individuals and society that come from sexual excesses far better than younger persons. As they look over the past, and remember the multitudes that have gone down to death from this cause, they are ready to cry out, "How shall the young be warned of their danger?" I have thought that, if some wise and kind-hearted physician of large experience could tell in a short treatise of a few pages the danger that comes to young people, depicting the sorrow and suffering in store for transgressors, no better work could be done for humanity.

* * *

AMOUNT OF SUGAR TO FEED TO SECURE A POUND OF SEALED STORES.

On p. 253, Apr. 15, Mr. Byer gives some facts on the value of sugar syrup compared with honey, and I can say that they are correct. I conducted quite extensive experiments a few years ago along this line in

order to find out just how far a pound of sugar would go; and, very much to my surprise, I found I could get only a pound of syrup sealed in the combs for each pound of sugar fed; and that a warm solution of two parts of sugar to one of water must be fed to secure that. If fed cold I got a small fraction of an ounce less; and when I fed half sugar and half water I got only $14\frac{3}{4}$ ounces, approximately, to each pound of sugar, sealed for winter stores.

* * *

DOES NECTAR FROM THE SAME PLANT VARY WITH THE SOIL?

Some years ago I scouted the idea of any given plant producing one quality on one kind of soil and another quality on a different soil. It begins to look as though my theories would not hold. I am told here in Florida that sugar-cane grown on rich low hummock land produces a very different syrup from that grown on high sandy land; also that the same varieties of oranges grown on low rich land are very different from those of the same variety grown on higher land. If the fruit is different, why should not the nectar of the flowers be changed to some extent also? It seems reasonable, and yet I am slow to believe the change is as great as some honey-dealers would have us believe.

* * *

VALUE OF INSECTS TO THE FLOWERS.

Mr. Geo. H. West gives us many interesting facts in regard to the value of insects in the fertilization of flowers. It is surprising to note the amount of information that has been brought to light since GLEANINGS took up the subject in a symposium some years ago. May I add one more fact along this line that I do not remember to have seen in print? Last winter, while waiting one morning I amused myself by examining some flowers of the sweet-scented jessamine that I had heard about from my childhood, but do not remember to have seen before. The first flower I examined carefully I found had a well-developed pistil, but no stamens in sight. This seemed queer, and so I looked for a mate and soon found another flower with well-developed stamens but no pistil in sight. Evidently insects must do their work or the flowers could not become fertile. I found on tearing the flowers apart that, where no pistil or stamens appeared, they were held back or underdeveloped only to mature a little later, and again to be cross-fertilized by insects.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

I am quoting the following from a letter just received from Mr. Geo. L. Emerson: "We certainly are having our share of hard knocks this year. The Governor did not sign our bill—so little rain, the frost, raise of freights on all bee commodities, to say nothing of tariff revision and consequent unsettled conditions. It takes a good deal to starve a beeman out, though, and I believe most of us will bob up after the flood settles down to a steady stream." Mr. Emerson is right. Let a good season come, and every beekeeper in the State would bob up, proud of his business, and would be telling every one he met how much he had made (with the possible exception of his creditors).

* * *

The best colony in my yard this season was a golden Italian. The second best, that of an impurely mated daughter of this golden. I have had goldens that were not worth introducing, that were apparently bred for color alone. But this one I purchased from an eastern dealer who advertised his queens for business as well as color. I purchased three for a tryout. One was a complete failure; one fair, and the other was the one just spoken of above. I am partial to the goldens, and see no reason why there could not be a strain bred from select stock that would be the equal of any strain, race, or color. Possibly one reason why they are liked so well by some beekeepers is because they look so much like gold that they look well during poor seasons when gold is scarce.

* * *

In a letter just received from Mr. M. J. Meeker he says: "I am surprised to see your quotation from Mr. Bixby's letter, p. 404, June 15. I think in fairness you should have made two other quotations." As Mr. Meeker has not given the quotations in full in his letter, and as he has the copy of Mr. Bixby's letter, I will give the quotations from memory as nearly as I can:

"This is no job for a tyro. I have been fooled myself. Also, I lost three-fourths of one yard from black brood when it struck this locality in an epidemic form in April."

I had intended no offense to Mr. Meeker, and I think those who care to read the matter in question will feel that I have not been unfair. I felt somewhat elated to know that there was a possibility that we were not so close to the disease as had been reported; and while I think Mr. Meeker is

doing excellent work as an inspector for the experience he had had up to the time he assumed the office of inspector, I feel that Mr. Bixby is one of the very best authorities in the State on black brood, so far as my knowledge goes.

* * *

In a late issue I mentioned having cured a case of paralysis by transferring the colony to a clean hive on clean combs (empty) and foundation. I also mentioned the fact of having another badly affected colony with which I was experimenting. I let it alone until there were scarcely bees enough to cover four frames, and then treated them the same as the first ones, but to no avail. They continued to dwindle until I was obliged to supply them with hatching brood to keep them going, meantime giving them another queen. The disease ceased after the original bees were apparently all dead; but my cure for the first colony proved of much less value than I was led to believe by their rapid recovery. Many beekeepers claim that this disease is worse where pure stock from breeders is introduced; but of these two, one was a pure-bred queen from a California breeder, and the other a native queen decidedly hybrid.

* * *

In the June 1st issue I spoke of our foul-brood bill having passed the legislature, which was correct; but it did not pass with our Governor, so we have been defeated after victory was in sight, and must now make the best of the law we have until we can do better. Many of our beekeepers will be sorely disappointed in having this bill defeated, and will blame the Governor for its failure. The blame doubtless would be correctly placed; but there are some reasons for its failure which can be traced to the legislature.

Early in the session just closed, the Governor gave the legislature warning that the formation of new commissions would not be looked upon with favor by him; further, that appropriations must not exceed the revenues available without extra taxation. The legislature passed several bills of the kind, among which was our bill, which, unfortunately for us, created a new commission in direct opposition to the warning. We, of course, did not know what the attitude of the Governor would be when the bill was drafted and presented to the State convention, and I suppose those who had the matter in charge at Sacramento did not

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

There is an active demand for bulk comb honey in the Texas markets, while the demand for extracted honey is "on the bum," as a number of extracted-honey producers have recently expressed themselves. There was a movement on foot several years ago, by several extracted-honey producers, to induce more beekeepers to produce extracted honey instead of comb honey, and then educate the people to the use of extracted honey. I did not favor this, and, instead, went into exclusive bulk-comb-honey production. I made no mistake, since the market demands an enormous amount of bulk comb honey over extracted honey, and that at a good price as compared with extracted-honey prices.

A beekeeping friend told me that he would just as readily have extracted honey of the same source as comb honey, on his own table, although we had to produce comb honey for the most of our customers. I do not agree with him, for I prefer comb honey to extracted honey from the same source, not because I like the comb or even the appearance of it, but because the honey itself tastes differently from that which has gone through an extractor. Honey just removed from the comb with the knife, and immediately eaten with your hot biscuit or bread, has all its delicate flavor and aroma, which makes it a delicate morsel. Take the same kind of honey, extracted with the machine, and it is not the same delicately flavored article. The agitation, and stirring effect upon the honey that has been "through the mill" is responsible for the loss of that delicacy and newness of flavor and aroma of our fine-flavored honeys. A certain change takes place; and a little experiment, that of taking a spoon and rapidly churning some of the fine-flavored liquid honey, will result in quite a different-tasting article.

* * *

HOME-MADE OR MANUFACTURED HIVES.

Every little while somebody asks whether it is not better and cheaper to make one's own hives and supplies. It may be a little cheaper to do so considered from the standpoint of the first investment; but aside from that I find no advantage—quite to the contrary. Especially is this so here in the South, where, first, we have not the suitable lumber for hive-making at a reasonable price; and, second, hives made with the lumber we have do not stand up properly. Therefore home-made hives are either too expensive on the one hand or too unsatisfactory on the other. My own experience

has taught me this, as I thought at one time I could make cheap and serviceable hives of my own. I have seen hundreds of home-made hives; and while they serve their purpose in a way, it is very disagreeable beekeeping indeed that goes with such hives.

The main trouble is that such hives warp, twist, or turn out of shape in all sorts of ways, even if they are made ever so carefully and expensively. All kinds of trouble confront the beekeeper at one time or another with these "leaky" hives, which let either the weather and rain or robber bees in, *but do not keep the inmates in*, just at times when this is most necessary. Besides, the apiaries composed of home-made hives never look so neat (except in the case of the very few exceptionally carefully home-made hives, which, however, are very much in the minority).

If any thing must be home-made, the bottom-boards and covers can be made well enough. But the hives and supers, and especially the inside fixtures, are better bought, and every thing will fit so well that rapid and more agreeable manipulations year after year will be worth enough more to pay the little difference between poor home-made hives at the best, and good hives purchased from a responsible factory. Bad indeed are hives and frames that do not fit exactly.

Continued from page 484.

feel at liberty to hash it up until it had no resemblance to the bill as sanctioned by the State convention. There were about one thousand bills which passed the legislature; and if press dispatches are correct, less than half of them were signed. Those passed carried appropriations nearly double the amount available from normal taxation, so the responsibility fell on the Governor, who had to trim them until they would fit the State treasury. We are not the only disappointed bunch. There was one bill affecting this county to the extent of \$85,000 that met the veto. I regret the loss of our bill as much as any one, for I think it was just what we wanted; yet I do not feel that, under the circumstances, the Governor should be blamed altogether.

My bees are very strong, and the swarming I had been able to control for several years has "broke loose," and they swarm in large, massive clusters, mostly after 4 o'clock. Well, I thought I had them, but I have another guess coming.

Bradshaw, Neb.

C. B. PALMER.

Conversations with Doolittle

At Borodino, New York.

KEEPING COMBS THROUGH THE SUMMER.

"How can one keep surplus combs during the summer months? I have no trouble in keeping them up to July; but from then on to the middle of September, or when the weather turns cold for fall, I am troubled with the larvæ of the wax-moth getting into them and often ruining a part or all of those which are not held by the bees."

"The keeping of combs through the whole year, at any time when there are not bees enough to occupy them, from winter's loss, sale of bees, or any other cause, is something which sooner or later confronts every apiarist. Half a century ago our fathers melted up all combs for the wax they contained if they had not bees enough to give sufficient swarms so that they might be hived in them; these fathers knowing full well that the hives containing such combs would hold only a mass of cocoons and webs in the fall if they tried to keep them over.

"Four decades ago some one found that combs could be kept indefinitely by subjecting them to the fumes of burning sulphur, of sufficient strength to kill the wax-moth and its eggs, provided the combs were then kept in a moth-proof room or repository.

"A little later it was found that, if the combs were exposed to the air and light, each comb being separated from the next by two or three inches, all those not having pollen in them could usually be kept perfect throughout the summer months without further attention. By giving those having pollen in them to the bees, little loss ever occurred where the room in which they were stored had plenty of windows to furnish air and light. Where the combs contained honey, it was necessary to use screens at these windows in order to keep the bees from carrying this honey off.

"Then some sharp-eyed and keen-scented person, given to close observation and experimenting, discovered that any comb which was subjected to cold from fifteen to twenty degrees below zero would be free from the ravages of the moth forever afterward, provided it was stored in a moth-proof place. Such a degree of cold killed even the eggs which might have been laid during the warm days of late fall. Thus, step by step, knowledge was gained, until at the present time no well-to-do apiarist thinks of melting up combs for the wax they contain, with no other reason for doing so than the fear of their being destroy-

ed by the larvæ of the wax-moth, if he has a room that can be sufficiently ventilated so that the temperature may fall below zero on some winter night.

"When I began out-apiary work I found that a room was not necessary for this purpose; for after a trial of several years I concluded that the very best place to preserve empty combs was in the hives. But I think I hear my questioner saying, 'Do not the moth-worms destroy the combs in hot weather when they are left in the hive out of doors? No, not if the hives containing them are piled up in such a way that the moths can not get into these hives after the combs have been subjected to cold of sufficient amount to kill all life in the eggs or larvæ. The combs must, however, be wintered out of doors, or where they will freeze. As we have plenty of zero weather in this locality every winter I have said 'zero;' for I have not experimented with a warmer temperature. It is possible that less severe cold would kill the eggs. Perhaps some of the friends further south can give their experience in this matter. Of course, the reason the worms do not destroy such combs when treated as indicated is simply because the eggs that produce them have been destroyed by the freezing during the winter. This plan of preserving empty combs will not work, of course, except in latitudes where freezings are sufficiently severe to destroy the vitality of all that pertains to the bee-moth.

"When the extracting is done for the season, the combs can be put back in the supers, and these set under the brood-nest so that the bees may remove the honey which may remain in them. It will not be necessary to disturb them again until the bees are prepared for winter. These supers of empty combs are now piled up out of doors to freeze during the winter, and there they remain till wanted again, whether the next season or ten years later. Hives of reserved combs of honey are piled up in the same way, and I have never found any worms in or among such combs when thus treated, even where the combs are packed in as closely as the hives will hold. I think it best, however, to remove one or two combs from each hive, and then place the others at about an equal distance apart. In this way surplus combs can be kept the year round, thus saving the labor of carrying them in and out, also the expense of providing extra room for them, and they remain bright and free from mold when in hives properly made."

General Correspondence

BEES AND THE RAINBOW—A COLOR STUDY

A Reply to John H. Lovell on Page 60, Jan. 15

BY ARTHUR C. MILLER

I know that I am quite likely to have a Lovely time, but I like 'em. I am a most peaceable man, and dearly love a "scrap." There is only one thing finer than a Donnybrook Fair, and that is another one. If you never attended one it is high time you did. You will get a jolly good broken head.

Well, my coat is off. Are you ready, boys? Go! "Why do bees dislike black?" They don't! No, sir; they don't! Did you get that?

Who said they did? Well, Lovell said that Crane said that it was "the almost universal opinion." I knew it, I knew it!—just plain hearsay evidence—the kind they hanged witches on. And here are some of the hearsay proofs: "Twelve chickens running in a bee-yard; seven black ones are stung to death while the five light ones escaped." Do you know where the light ones came from? I'll tell you. Their feathers turned white from fright and saved their lives.

"A dog with a black rump is badly stung on that part." Sure, why not? The bees were after that wagging tail. "Never strike at a bee."

A white dog and a black dog ran among the bees. The white one did not attract *much* attention, while the black one was furiously stung. Please, how many stings are embraced in that "much?" To have that proof good for any thing, the dogs must swap either skins or dispositions.

Then there is cited a black hat "literally decorated with stings." Humph! Probably out of style, and the lady bees resented such a thing in their midst. A black hatpin caught it. Probably longer than the law allowed. Black stockings peppered. Men's or women's? Whole or darned? Those points should be specified, for they have a bearing on the pepper.

So much for your whacks. Now take these:

Bees *like black*. They just revel in it. They get so tired of sailing on the waves of light in their search for grub that they rejoice to get into the black where there are no waves. We enjoy sailing on the bright blue waves ourselves; but the bees find too much of them depressing. Now, red they rather like. "Red in moderation is a warm and stimulating color, but in excess it becomes an irritant." I've heard it said of "wine when it is red," and all you beekeep-

ers know how fond the bees are of fermented drinks. Obviously, after a surfeit of the "reds" black is most soothing. But look out for their tempers "the morning after the night before."

"Way down East" the bees voice no antipathy to black winter cases. Being inside of them in the winter, naturally they do not.

"A black surface in bright sunshine is several degrees warmer than a white one. This additional heat may also exert some influence in attracting the attention of the bees, though it is doubtful." Do you hear that, E. R.? Just reread it. It has only a little to do with the bees' consideration of black, but a whole lot to do with good wintering, as I've told you a lot of times. We are not talking on wintering, so you are not to mention it in your footnote; only just remember "I told you so."

Down in this locality we have our telescope covers black—a real pretty dead black, both *summer and winter*, and sitting right out in the sun too, which is the exact opposite of what all the Solons of beedom say should be, and that is why I did it. Oh! they are a success, and the bees fairly *love* those black boxes. On their return from an early morning scramble in the cold dew-covered blossoms you will find them warming their chilled toes on those nice warm black covers. As I said before, bees just dote on black. But they dislike brown and blue and white and red and a whole lot more colors. Oh, yes! it is so, and I'll prove it.

My friend 'iggins (his real name is Higgins, but he is English, and his *hatches* bother him, so he drops them), well, as I was saying, 'iggins has a real nice soft brown felt hat—one of those mellow woodsy browns at the start, and more mellowed by the wind and the sun till it so resembles brown leaves that, when he throws it down in a corner of the beeyard, 'tis hard to see—at least for him, and he is always looking for "that bloomie" 'at," for he keeps it anywhere but on his head when in the beeyard. That hat is so full of stings that he had to sandpaper the points from the inside in order to wear it.

If you will come on here I'll get 'iggins to let you try his precious hat for a few minutes. Two or three minutes will be quite long enough to suit you.

Pat, the friendly helper at one of the yards, usually wears a black shirt and a pair of old blue overalls. Pat is a pretty good beekeeper, and the bees are kind to Pat. A bright small boy on the place was

interested in the bees, so he donned overalls and jumper of the same blue material as Pat's overalls, but brand-new. Also he had on a good wire bee-veil, and tucked his hands deep into his pockets. Pat and I were busy when the small boy sailed in joyously, telling of his outfit. Very shortly there was a wail as of fear, and, turning quickly, a sight met my eyes that frightened me, seasoned veteran that I am. Those blue garments were almost hidden under a seething, hissing mass of stinging bees. Literally thousands of them fastened by their stings and thousands more were coming from everywhere. Italians, hybrids, blacks, all were at it. I grabbed the boy in my arms and fled. I took him indoors and killed every single bee before I dared remove his veil or garments.

Since then I have found that bees always assail that kind of cloth when it is new. Probably the odor of the dye is the cause, for it has a strong and peculiar odor.

One old man who is very fond of bees is also fond of old-fashioned red handkerchiefs—"bandanas." He used to wear one around his neck, but the bees just loved to pepper it, and now he doesn't wear it so any more. The bees sometimes missed their aim, and he "got it in the neck," you know.

White gloves, particularly after once or twice wearing, are used by the bees for pin-cushions. Unfortunately, the stuffing in these pin-cushions is alive, and wiggles as the pins come through, and it bends the pins.

Black bees for a few hundreds or thousands of years have managed to survive without stinging each other to death despite their color. When a few Italian queens are put in an apiary of blacks or Carniolans or Banats, we do not find the Italians stinging all the black-colored bees to death. On the contrary, if we do not meddle, it is but a few years before the Italian blood has vanished. You see the bees love black.

A small apiary is located in the middle of a large apple orchard, which is kept tilled by a hundred or more hogs big and little. The apiary is surrounded by a wire hog-fence which, while it keeps the hogs from getting within two feet of any of the hives, does not keep the bees from getting out. Most of the hogs are white, and perhaps half a dozen black or spotted. The bees never molest any of the hogs, either black or white, no matter how cross the bees are with the beekeeper.

Another apiary is located beside a cow-pasture by the corner near the barway, and there, of course, the cattle congregate. Rarely does a bee bother a cow, and the black Holsteins are quite as safe as the red or

red-and-white cows. (Those bees like that shade of red.) But a pair of gray mules always make it a point to pass the apiary on the double quick.

In an apiary of about one hundred and fifty colonies in the State of New York there roams a cow—not that the beekeeper likes the cow or dotes on aroma, but the only place for his bees was the cow-pasture. The cow is a Jersey with black muzzle and black brush to her tail. It is a pet cow, a dear sweet thing to the family, but a confounded nuisance to the beekeeper, for she is forever nosing around when he is at work with the bees. The bees apparently do not know the cow exists. They will sting the beekeeper, but not the cow, not even her waving black brush. I know, because I watched. You see, the bees *like* black.

An apiary in North Carolina is owned and operated by a *black* man, not one of the chocolate-brown blacks, but a real black black. Did his bees constantly assail him? Not so I could see it. On the contrary, I got the stings. If bees emerging from a dark hive see a black object more readily than a white one, they should have attacked him rather than me, confound them!

It is a question whether the sudden change from dark to light or *vice versa* affects bees' vision at all as it does ours. Every observation suggests quite the contrary. Flashing light attracts their attention. The shiny-black hatpin head, the sudden removal of shutters from a glass hive, etc., are examples; but apparently it does not affect their vision.

In one of my bee studies I experimented with a house of white cloth. In dimension it was nine feet cube. It was all white. Even the floor was covered with white cloth. The hives were white, and I donned a white duck suit and white duck hat when at work in there. Most of the time the hives used were of the baby-nucleus type, about eight inches cube with a half-inch hole as an entrance.

Were the bees confused when they emerged from the dark interior of the hives into the brilliant white room? So far as could be seen, no. Following are a few of the interesting things observed:

The bees—workers and drones—would come out of the hives, circle once or twice without touching the cloth walls, and then shoot across the room bang into the north wall, and always above a certain level. I was puzzled until I took a position so that my eyes were on a level with the position from which the bees started, then I saw distinctly the line *over* which they were flying or attempting to fly. That line was the hazy and irregular horizon formed by trees

about a dozen rods away. Below that horizon the wall appeared a faint gray (dilute black), and above it strong white. Why they tried to go that way instead of through the brilliant east wall (morning observation) I do not attempt to explain.

The house was then covered with another layer of white cloth with a space of one inch between the layers. The bees at once ceased the attempts to go over that tree-line, for it was no longer to be seen; but they did something else. In the early morning, say from five to seven o'clock (mid-summer observations), they started for the "bright spot" where the sun was to be seen through the east walls. When the sun got more overhead they flew about freely, working on food in the center of the room and carrying it back to their hives.

The hives were placed on the floor close to the walls, entrances all pointing to the center of the room. Sometimes there was only one hive, sometimes four or five. The hives were all alike; and when four were used one was in the middle of each side of the room, yet the bees and virgin queens always found their way into their own hives. How did they do it? I am not answering that question. It is up to you.

One day when showing the work to a guest, I had to do more or less talking, and several times bees flew toward my eyes or mouth. Several times when in conversation in the apiary I have had bees fly into my mouth, and been stung on the tongue—hot sauce, I can assure you—really quite ahead of Tabasco. Why did they go for the relatively dark cavity of the mouth? Did they see the red? Or was it the wagging tongue?

In the cloth house, bees tried to go through black or dark objects, resulting in bumping their heads and making them fussy. Then they would back off, come up slower, and apparently "feel their way" up to the object. If it was a hard substance they sometimes hit it forcefully enough to stun them. If it was fuzzy like black felt they sometimes, after hitting it, would hover angrily before it.

My interpretation is this: Bees do not readily measure their distance from black objects, and in rapid flight strike them before they realize they are close to them. Irritation, of course, follows; and if the slightest hint of poison was deposited on the object, or the object has an odor or motion, the bee pitches in to "do up" the fellow that hit it.

If any object, regardless of color, gets an odor of bee-poison on it, bees will surely assail it as soon as that odor is perceptible to them. If the object is a hat or gloves or some other garment, only two courses

are open as a remedy—namely, deodorize the article or change to clean ones. The odor of bee-sting poison is quite tenacious, and not easy to obliterate.

The bee's sense of smell is much keener than its sense of sight, hence it behooves us to keep on apparel free from sting poison. Once let gloves or hat get well scented with it, and your name is 'iggins.

We all know how peevish the bees are after a storm, but how many know the cause? It is this: The bees' nerves are rasped by the colors of the rainbow. Rainbows are perfectly beautiful, but the color waves make the bees so seasick that they just want to die, and you are the opportunity.

Providence, R. I.

BEES DISLIKE BLACK FURS BECAUSE THEY RESEMBLE BEARS

BY FRED J. CARTAN

I have read with considerable interest the article by John H. Lovell, "Why do Bees Dislike Black?" and while he may be correct I have often thought that the anger aroused in bees by the appearance of any black hairy animal was a survival from past ages when the ancestors of our little friends made their homes in the trees of the forest as well as under ledges, and perhaps in the ground.

During the time I have lived in Oregon I have found a good many bee-trees; and to the best of my recollection every one bore the mark of bear-claws. Some of them (old homes of bees) had been visited many times by Bruin in a vain endeavor to despoil the inmates of their stores of sweets. It is a well-known fact that bears are very fond of honey, as well as of the brood and even fully developed bees.

I have a neighbor living near one of my beeyards who, two years ago, had several stands of bees located about a mile from his home. They were found by a bear; and from the "sign," Mr. Bear had made several visits and had devoured every thing but the hives and frames. He had picked up the hives in his "arms," and carried them over a common rail fence into the brush, and no two in the same place.

Now, the black bear is a tree-climber, and is widely distributed over the earth. That the wild bees have had to fight the black bear for untold ages will not be doubted by any one at all familiar with the animal's traits. This being so, would it not account for the bee's hatred of black, and especially of a black furry animal? I am inclined to think that it is a survival, the same as their

actions under smoke and others that we are familiar with.

Corvallis, Oregon.

A BLACK HAT THAT PROVED TO BE A TARGET FOR THE BEES

BY THE BEEMAN

Three years ago I hired a man to help take off the honey. It was after the flow was over, and the bees are cross when there is no flow. We wore veil and gloves. The hum of the mad bees soon attracted my attention to his black hat. The bees were not bothering me; but the black hat about four feet from me had nearly a dozen stings, and the bees were very mad. We left the yard, and I brought out a straw hat for him. We went to the same place in the yard to work, and the bees did not bother us. A few days later he went with my brother to an outyard, and wore the black hat. He put on a veil and left off the gloves. The bees attacked him at once, and they soon found his hands. The next day his hands were swelled badly. My brother did not have his veil on; and the bees, being mad, attacked him, and then he put on a veil, and took the honey and carried it to a wagon, as the man with the black hat could not go into the yard.

I have been run out of the beeyard on account of my black hat a number of times. We wear veils only when the flow is poor; and if I stop in the yard to see how the bees are working they soon find the black hat. I will not buy another black hat while I work with bees. Sometimes I get stung while walking through the yard without stopping; and when I am going to the yard, if I have the black hat on I change it unless I forget it.

Chamberino, N. M.

A CONVENTION OF LAYERS

Requeening; Laying Workers

BY R. F. HOLTERMANN

One evening when visiting Mr. Hardy in New York the question came up regarding requeening apiaries. Mr. George B. Howe considered queens up to two years of age quite profitable, of course requeening whenever any showed signs of failing powers.

Messrs. Howe and Hardy considered the month of October a time when bees accept a new queen very readily. Mr. Hardy had often successfully introduced a queen at the entrance, running her in during the early cool morning, and Mr. Howe said that he

had frequently introduced queens to queenless colonies by running them in at the top of the hive in October in the early morning.

MATING OF QUEENS.

In 1908 Mr. Howe had three queens mated twice. Three days after the first mating they mated again and laid three days after the second mating. Mr. Howe had eyewitnesses to this at the time. Normally in a honey-flow queens lay three days after mating; but it is dangerous to consider a colony queenless, even if no eggs are in the hive for quite a time after a virgin queen hatches. He had known of a Carniolan queen not laying until three weeks after she emerged from the cell. Italian queens are often slow about mating and laying. If such queens were too slow, he found it best to destroy them. Virgin queens often come out several times to play in front of the hive before going out to mate. Mr. Howe said that queens would sometimes be drone-layers when they began laying, and would become normal queens afterward.

LAYING WORKERS COME FROM OVERFEED LARVAE.

A discussion took place upon the subject of laying workers. Mr. Howe's many years of experience with bees warranted him in making the following statement: "You never find laying workers in queenless colonies in the spring. Some varieties of bees are more liable to have laying workers than others. Those more liable are those which feed the larvæ more.

"If during the breeding season you kill a queen and destroy all the queen-cells after seven or eight days, then fertile workers will develop; but I never had a case of fertile workers in a colony of black bees. In a Carniolan colony, if you kill the queen and then destroy all queen-cells, after eight days laying workers will soon develop. I have seen in such a colony as many as 50 or 60 laying workers. I have quite frequently seen them back down in the cell to lay. The normal workers in a colony will feed the laying workers. The latter are plumper than ordinary workers. I find fewer laying workers among Italians, and none at all among the blacks.

"I believe that overfed larvæ, when the colony is hopelessly queenless, produce laying fertile workers. A colony having no brood when queenless can not overfeed larvæ to produce fertile workers."

The writer suggested that the reason why there are so many eggs in some cells in which laying workers laid was because, unlike the queen, the workers do not examine them before they lay in them. To this, both Mr. Hardy and Mr. Howe assented.

President Collins showing a thrifty, three-year-old queen. When bees are gentle Mr. Collins never wears hat, gloves, nor veil; and where is the smoker?

SOME BEEMEN I HAVE KNOWN

Introduction to the Series

BY WESLEY FOSTER

One can not fully understand the principles of beekeeping which enter into the success of a beekeeper unless he knows something about the man mentally, morally, and physically. The man is the factor to be considered. In these little biographies I hope to give my readers a more or less accurate view of the men involved, and, by so doing, bring out to view the reasons for their success with bees. If one can see the man he can see why and how he raises good crops of honey. And then, again, one is more interested in the men than in their bees, any way. 'Tis human nature to want to know our fellows.

I can not write of these men's faults. The faults do not add to their success, and will not be mentioned.

In telling of the men I will drift into a description of their work and surroundings, which is inevitable. Psychology has declared that a man's clothes are literally a part of him, the same as his body is; and so I shall consider that I am treating of a man's personality when I tell of his apiary, auto, honey-house, smoker, or hive-tool. We are now off for a merry visit with the first one of our friends.

W. P. COLLINS, BOULDER, COLO.

In the year 1898 or 1899, upon my return home from school one evening my

father was talking bees with a stranger in the road that passed our house. This stranger had a thin bony frame, and the clothes he wore accentuated the angularity of his frame. He leaned against his bicycle and told of his beekeeping experiences in Wisconsin, from which he had come but recently—bringing fifty colonies in a car with his household goods. Father talked foul brood with him, and the peculiarities of Colorado as a bee country. This stranger with withered and freckled face, large features, and sandy hair, soon proved to be a good talker, with a brain working like chain lightning. He talked bees and socialism, telling of the initiative, referendum, and recall in Switzerland, and other phases of the socialist movement too numerous to mention. He was the first socialist I had ever met. A graduate of Wisconsin, coming out west to practice law, and bringing fifty colonies of bees with him, such was and is Mr. W. P. Collins, now president of the Colorado State Beekeepers' Association. He has increased his beekeeping interests, and still practices law on the side, and works in socialist propaganda at all times.

Mr. Collins is a fast worker, as any one will soon realize who works with him for a day. His system of work is to do the most important thing as it comes to hand. I want to tell a story that may have grown by retelling before it reached my ears. One day during honey harvest our sandy-haired friend brought in a load of honey, unhitch-

An outdoor colony in the top of a turpentine tree. Photographed by W. H. Nixon, Manning River. From V. J. Everingham.

An amusing and common sight to Boulder residents is that of Mr. Collins, clad in white coat, shirt, and trousers (his regular apiary togs) riding home on his bicycle with the smoker strapped to the handle-bars, puffing away as if it were the motive power. The rest of us beemen here in Boulder are so common in appearance and actions that we are unnoticed; so Bro. Collins in the people's mind is the king-bee of the vicinity. When he loads a car of honey the papers say, "W. P. Collins, the bee-wizard, is loading a car of honey," or "Collins, the beeman, reports heavy losses of bees," or "has had a good crop," etc. He is the type for the publicity man. That's the reason I am writing about him.

President Collins operates about 700 colonies of bees at Boulder, and is interested in 400 colonies more at Rifle, on the western slope, 300 miles distant. He harvested 400 cases

ed, put out the team, and went to supper. During supper some one over town called him up on the phone and asked to see him on a matter of business. Mr. Collins met the appointment, and did not return until about eleven-thirty, when he thought of that load of honey still on the wagon, and that another load must be brought in on the morrow. So he began carrying in the honey. An elderly widow living close by saw dimly in the faint moonlight a figure going in and out of the honey-house. Thinking that a thief was at work she called up police headquarters. Two patrol men came down and caught the thief with the goods on, hustled him off to headquarters, waving aside his protestations as ridiculous that *he* was the *owner* himself.

this season from these western-slope bees, and made but two trips to do it. That's going some, but Collins always "goes."

As a presiding officer President Collins is unexcelled. No time is wasted at the sessions of conventions when he is in the chair. He has been president of our Colorado Association for six or seven years.

Brother Collins is a great joker; and if there is any thing above socialism and bees to engross his interest it is just plain "josh." He is generous, kind-hearted, and liberal. He will not quibble over microscopical points, but is ready with wit and cutting invective when he lets himself loose on some question he deems important. There is nothing selfish in his makeup, and he is a good neighbor, loaning any thing he has

that you can use. He can beat an opponent in debate by throwing out arguments with gatling-gun speed. First the opponent becomes confused, then flees amid the cloud of smoke that engulfs his hazy mind which can not grasp nor connect the various points of the onslaught.

President Collins is an effective institute speaker on bees. He has enthusiasm, and gives life to any thing he tackles.

Boulder, Col.

COMB BUILT IN THE TOP OF A SMALL TREE

BY V. J. EVERINGHAM

The photo shows comb built in the top of a turpentine sapling by a colony of bees. There are seven well-formed combs, containing a fair amount of brood and honey, with a fairly strong colony of bees.

They were photographed a year ago last June; and, judging by the way they have built up, they must have taken up their abode there the previous summer.

We took the combs from the branch and grafted them into Hoffman frames, and so far they are doing very well.

Taree, Manning River, N. S. Wales.

FERTILIZING QUEENS AT A MATING STATION

BY DR. BRUENNICH

In the years 1870 to 1880 the beekeepers of Switzerland were troubled badly by the *crossing fever*. They thought that, by mating a black bee with a Carniolan or an Italian, the good qualities of the parents would be inherited, and they could thus be able to create a wonderful new race. This was, indeed, a very childish idea, and the fruits were not attractive. We who have since learned the law of the alternating inheritance of Mendel are not surprised that

Breeding-case for holding four glass mating-boxes.

the results were so little encouraging. In the following years we learned that the black race was the best for our conditions, and we began to deplore the introduction of the foreign races; but, unfortunately, it was almost too late. The greatest part of the apiaries were mixed, and it was not easy to find some colonies which, in consequence of their isolated situation, had preserved their integrity. The question was, *how to keep pure* those colonies in the midst of all the hybrids. Success was made possible, first, by our glass mating-boxes; and, second, by our mating-stations. The latter are isolated places containing a strong pure colony with a great many drones, and far enough from other apiaries to secure pure mating. The more drones there are, especially young and vigorous ones, the greater the probability of pure mating. But as there were many beekeepers who made use of the station it was absolutely necessary to have a strict control to hinder the entrance of "gipsy" drones with the nuclei. This was made possible by the glass mating-boxes which were introduced, I believe, in 1897. I have been working eleven years

Dr. Bruennich's glass box used as a mating-hive.

Funnel and glass box with excluder.

with the glass boxes, and I know their great advantages.

The choice of the stock for breeding must, of course, be a most careful one. I demand from a queen of which I wish descendants that she be at least three years old, her colony during those years being ahead of the

selection has to take place with the colony furnishing the drones, and the old age of the queen is here still more important.

As to the rearing of the queens I think I have nothing new to say. The matter is known well enough. The mature queen-cells are put into an incubator or into little cages

of wire in a strong colony till they come out. In the first, the temperature must be 99 degrees F., and the young queens must have at their disposition honey and water. I generally have the cells in little cages where I introduce from ten to twenty bees. Before making up the nucleus I mark each queen on the back with color. Mark a few drones first before attempting to paint a queen. With the left hand I take the queen by her wings, holding her slightly on the plate of the table, and with the right hand I give her the mark.

The illustration shows my own construction, which I have used many

A, a button for holding the glass; B, a groove for the glass; C, a staple for holding the frame; E, F, holes for feeding; G, entrance; H, hole for ventilation, corresponding to a groove in the front of the breeding-case.

Rendering wax out of bees. See page 498.

years. An important feature is the distance between the two glasses, which has to be exactly two inches. The size of the comb ought to be at least 60 square inches. The glasses may be capable of easy removal, without disturbing the bees. Four of those glass boxes are placed in a breeding-case. Two or three may be used if desired. A most important thing is to have the entrances as far as possible from each other and quite different in shape and color. On the top of the glass boxes I put a warm cushion.

In the box the frame should be provided with a little strip of foundation, and there should be about a pound of Good candy opposite to the entrance. The candy is made in an easy manner by warming, let us say, 4 lbs. of honey; and, if it is quite liquid, adding 8 lbs. of the finest powdered sugar. This should be well stirred with a wooden stick, and at last poured out on a board where there is a thin layer of sugar.

It is better if the combs for the boxes are prepared in the following manner: In a regular honey-frame put in two or three of the mating-box frames with foundation, and with a piece of wood in each, in order

to get a large opening in the comb, as shown in the illustration. This is very important, because the bees will be far more friendly to the queen, and the latter will have more chances to be promptly fecundated if the bees can form in that free room a little swarm. Give the large frames to a strong colony, and then feed syrup till the box frames are well filled with food.

The glass box being prepared, the next move is to form a droneless nucleus. I remove one of the glasses and set in its place a piece of perforated zinc. On the front I have constructed a kind of funnel into which the bees (without queen) are thrown. The bees must be young and hungry, otherwise they will remain in the funnel and not enter the perforated zinc. When there are bees enough the zinc is removed and the glass replaced. The nucleus is now caged, and the bees left alone some minutes to fill themselves. Then after giving a knock against the box we introduce the queen through the little entrance. If there are many old bees it is sometimes necessary to blow in a mouthful of tobacco smoke. Quite a sure way is to put in the queen before forming the nucleus, placing

A honey exhibit in New Zealand in which the granulated "Pats" are especially featured. See page 500.

A bunch of steers enjoying their first meal of sweet clover hay. See page 500.

her in a little tube of wire closed by candy. Four of the boxes (or two or three) are placed in the breeding-case and brought to the mating-station not earlier than the following day, in order that the bees before flying out may be accustomed to their home and to the queen. After ten days, as a rule, the fertile queen can be removed, which is extremely easy to do, and two or three days later a new queen can be introduced in a candy-cage. The great advantage of these glass boxes is the easy and quick control, without any disturbing of the nucleus. A further gain is the possibility of various observations through the glass.

In the picture I show a simple feeder which is made of a zinc box, the opening being covered with a piece of gauze.

Zug, Switzerland.

MATING-STATIONS

BY J. A. HEBERLE, B. S.

Numerous mating-stations have been started of late in Germany, Austria, and Switzerland. It is the Swiss, with their thorough organization of beekeepers, who, about fifteen years ago, started the mating-stations. Since then, every year the beekeepers who pay special attention to queen-rearing have a meeting—a breeders' conference. For two days the methods of queen-rearing are thoroughly discussed and experiences are exchanged. Lectures and dem-

onstrations make this conference very interesting and instructive.

From the first conference on, they selected with care a few of the best out of a large number of colonies for mating-stations and for queen-rearing. Eggs were sent by mail, so that many could rear queens from a colony that had distinguished itself. Only black bees (natives) were considered; but these had been crossed with Carniolans, and, to a small extent, with Italians, which increased the difficulty of pure breeding considerably. Surely much must be accomplished where so many work systematically with intelligence and patience on one problem.

These breeders were not satisfied with just rearing queens from selected colonies. They wanted these selected queens to be mated with drones from choice colonies. Mating-stations were established. Colonies were selected with special care as to characteristics and qualities to blend harmoniously with the selected queens. Colonies placed at these stations are called "droehne-rich" or drone colonies. The stations are placed in as isolated places as possible. There are reports in bee literature that bees fly as far as five miles. That would imply that within a radius of ten miles no apiary and no wild bees should be found, to be certain of pure mating. Such a distance, however, is not necessary. Three miles I consider sufficient to ensure a high percentage of pure matings. If at all times a large number of drones are flying at the station, good results will be even attained at a dis-

tance of less than three miles from the nearest colonies.

The virgins to be mated are often sent a considerable distance to a station to be mated. No drones must be among the bees that accompany the virgins. Each station is in charge of a beekeeper who receives the virgins, carries them to the station, and, when mated, sends them back to the owner. Usually one or two days in the week are set apart for this, so as not to make too much work for the man in charge. By such careful breeding it can be reasonably expected that the hereditary power is greatly increased, and that a large per cent of the progeny will show the good qualities of the parents.

In 1911 Switzerland had 33 mating-stations; 417 breeders sent 3899 virgins, of which 3296 (84 per cent) were returned as fertile queens to the owners. The most successful station had 95 per cent; the least successful, 66 per cent of the virgins sent returned as fertile queens. In 1912, 41 stations were in operation, and 457 breeders sent 4013 virgins, of which 3162, or 79 per cent of them, were returned fertile. The most successful station returned 94 per cent; the least successful, 58 per cent, as fertile queens. The unusually bad weather in 1912 accounts for the greater loss of queens last year as compared with the losses of 1911.

Queen-rearing years ago was much influenced by American methods, especially that of Mr. Doolittle, but now they have worked out a way of their own that seems satisfactory. Special attention is paid to the colony that has to rear the queens. This colony should be in the same condition as one preparing to swarm. It is claimed that then the larvæ are fed and tended with the utmost care. Dr. U. Kramer, President of the Swiss Beekeepers' Union, is also chief of the queen-rearing division. He wrote an excellent work on queen-rearing for conditions here and where quality only is looked for.

Markt Oberdorf, Bavaria.

This toad has enjoyed many a warm meal from the alighting-boards in my lee-yard. Probably his sour expression is due to the many stings he received. When I photographed him his stomach was full of bees.

Swift River, Mass.

A. E. WILLCUTT.

THE HATCH PRESS FOR WAX-RENDERING

Burlap Sacks Preferred to Square Pieces

BY WM. BEUCUS

Those who, like myself, have built up from a few colonies to a number sufficient to make a living from bees have, no doubt, passed through all of the trying experiences incident to wax-rendering without suitable appliances. And these heroes and heroines will, perhaps, find it difficult to suppress groans at the recollection of the many utensils which were, one after another, pressed into service in separating wax from even a bushel of old combs. I feel sure that, as remembrance revives all the feelings of irritability attendant upon the actual process of separation and the tedious cleaning-up which necessarily followed, these tried and worthy beekeepers will breathe earnest expressions of assent when I say that, even if the number of colonies kept is only a few, investment in some kind of wax-press is advisable. The disagreeableness of the labor is not the only thing to be considered, however. The loss of temper is serious enough; but the loss of valuable time and the loss of precious bright yellow wax are still more serious. How painful it was to us, after all our pressing and squeezing, to see, here and there, in the slungum, little streams and puddles of beautiful golden wax!

But this is all changed now. We have an outfit which enables us to secure almost

all of the wax without loss of temper, with a much smaller amount of labor, and with a feeling of satisfaction which is pleasant indeed. We have been told, over and over again, in the bee journals, to secure a wash-boiler, or perhaps two or them, in which to melt our combs over a stove, and, with a dipper, to dip up the melted combs and place them in an outspread piece of burlap in the wax-press. To us this seems all wrong. To begin with, the best place in which to work is the good old outdoors, where there is an abundance of room and where we may make as much muss as we please. Next, a wash-boiler is too small, particularly if one has 100 or more colonies. Further, dipping with a dipper is a waste of time; and, last, a square piece of burlap, which we are advised to use in the directions which accompany the Hatch wax-press, is a nuisance.

When we began using our Hatch press we blindly followed directions. The combs were dumped into the tank (4 ft. by 2 by 1), and were transferred with a dipper to the press. The loss of time, with the consequent cooling of the wax which accompanied this dipping, soon disgusted us. We then made a frame of slats; with stones we weighted it down to the bottom of the tank, and placed in each of several gunny sacks two sets of old combs. The mouths of these sacks were tied securely, and they were thrown into the tank. The advantage is obvious. With a stick we could remove one of the sacks from the boiling water and place it in the pan which had been momentarily transferred to the corner of the tank. The steaming mass could then be quickly

placed under the screw, a little hot water quickly added with a pail, and the pressure begun.

Now I must call attention to an additional appliance which I think will prove a boon to my fellow beekeepers. It is the Aiken wax-honey separator used as a wax-water separator. The one we use was made

out of a 60-lb. can. The tube to the right, shown in the drawing, comes from the bottom of the can and extends up to within about $\frac{1}{2}$ inch or a little less of the spout to the front, and carries off the excess of water. This hot water may be emptied back into the tank, thus saving the heat it contains. This separator had been used to separate honey and wax coming from the capping-melter, and for this purpose the little tubes, $\frac{1}{2}$ inch in diameter, were large enough; but for separating wax and water each should be of the same diameter as the spout of the wax-press. The reader will readily see why. If nothing but water is coming from the press it can not escape fast enough, and, as a consequence, the layer of wax rises, flows off, and is followed by water. On the other hand, if nothing but wax is entering the separator, the layer will become too thick, will harden before it can escape, and thus clog the opening.

It is our intention to improve our outfit by uniting the water overflow with the tank, thus saving more heat and the time wasted in emptying by hand.

In order to have the separator work well out of doors it is necessary to have warm weather and to work fast.

Cadott, Wis.

[When we began rendering wax from old combs we used burlap sacks to hold the refuse in the press. On the advice of a number of other beekeepers, however, we tried the square pieces of burlap; and after getting used to them we found that we preferred them, for they do not burst quite as easily as the sacks, and it is not so difficult to shake out the refuse after it has been pressed. Furthermore, a smaller receptacle may be used for melting up the combs if they are merely thrown into the water, and there is less danger of starting the pressing before every particle of comb is thoroughly melted. It is true that it takes a little longer to dip the melted comb into the press; but if a pail is used for a dipper this part of the work takes very little time indeed; and by the new plan that we have recommended for several years, of leaving the plug in the outlet of the press, the hot water and wax do not escape at once but remain in the can, thus preventing the refuse from chilling.]

One advantage of the sacks is that they may be placed under the framework, and then, before the pressing commences, a large amount of wax may be dipped off the top of the water, so that there is much less in the refuse at the time the pressing begins.

We have used the wax and water separators, but we really prefer the simpler out-

fit, consisting of a can perhaps two feet in diameter and three feet high, with a gate or faucet at the bottom, from which hot water may be drawn as it is needed. There is no danger of drawing off the wax, for it is not necessary to lower the level of the contents of the can to the danger-point. In this way the hot water does not run out all the time, but only as needed, and there are no tubes to become filled up with cold wax if one happens to forget.—Ed.]

CUTTING GRANULATED HONEY FOR MARKET

Some Further Results of the Plan as Practiced in New Zealand

BY JAMES ALLAN

[This article, by an oversight, was held over two years before being published. The subject matter is still of interest, however, for we believe there has never been as much interest shown in marketing granulated honey as at the present time. We regard our contributor's plan as being a most practical one.—Ed.]

On page 707, Nov. 15, 1909, appeared an article by me on the "pat" system of preparing extracted honey for the market. The article explains the methods adopted, and also gave the results when the honey was placed on the market. However, no notice of the system has been taken in any subsequent issue of your paper so far as I can see, and I am led to the conclusion that your readers do not recognize any value in it. Perhaps they are right; but it will not do any harm. On the contrary, it may do some good if I give another season's experience along the same line.

In 1910 (a poor season) my honey crop was 5700 lbs. of extracted honey. Of this 5000 lbs. were put up in ½-lb. pats and sent to an agent for sale, and in less than a week I got his sale note to let me know that it had realized 3 shillings per dozen or 6 pence per lb. Now, just a week before sending this agent my honey I was in his store and saw tons of honey in 60-lb. cans, just the same quality as mine, waiting for a buyer to come along and take it at 3¾ pence per lb. Now, what I claim is this: That my honey sold quicker, realized 50 per cent better value, and will reach a satisfied consumer quicker also; all because of the method of putting it up. While the difference in the cost of the packages is very small, at our prices the 60-lb. cans and shipping cases required would have cost me about \$34.00, while the cost of wrapping papers (double wrapping each ½ lb.), and shipping cases, was actually \$46.74. The time required to wrap and fix for market the 5000 lbs. would be about 4½ days for myself and two girls.

They say the dollar is what appeals to an

American heart. I don't know but it should surely make an American look into the business when I say that the result of the pat system was to give me \$200, or, in our money, £40 more for 5000 lbs. of honey than I otherwise would have received.

I enclose with this a photo of an exhibit we sent to a local winter show. In it the pats have a prominent place. The center block is 100 lbs., and shows the tin slides. Each of the divisions, when cut, gives 25 ½-lb. pats. Quite a number of others are adopting this method here, and we think it has a future before it.

Wyndham, Southland, N. Z., June 23, '10.

CATTLE AND HORSES LIKE SWEET CLOVER THE FIRST TIME THEY SEE IT

BY HARRY D. HOWLAND

The engraving shows our steers eating their first feed of sweet-clover hay. It is difficult to see in the picture what they were eating; and as it was thrown in on top of cornstalks, which are light-colored, they show up better than the hay.

During the fall they ran on an oats stubble with red clover in it, and a strip of about one acre of sweet clover. We could not see but that they fed as much on the sweet clover as on the red in proportion to the amount; but as it grew up taller and coarser than the red they did not feed it down as short.

We fed some of the hay to our horses last fall, and thought that they liked it better than timothy. Some of these horses I know had never eaten sweet clover of any kind; for until just recently we have been particular not to let it grow on our farm, as we did not know its value, and considered it a nuisance.

Last spring we mixed sweet and red clover seed together, and sowed a narrow strip of the oat-field with it. On the lower ground the sweet clover made a luxuriant growth after the oats were cut; but the red clover didn't make as much growth as where there was no sweet clover with it. On the high ground in this strip the sweet clover made a growth of only a few inches, while the red grew a little taller. Upon testing the soil we found that there was very little or no acid in the low ground, while the high ground showed much acidity. From this experience we conclude that sweet clover requires more lime in the soil than red clover. We are covering a 30-acre field with two tons of ground limestone per acre on which we will sow an early variety of oats and sweet clover this spring.

Gardner, Ill., Feb. 22.

SIFTING TO FIND THE QUEEN

A Quicker and More Convenient Method

BY G. C. GREINER

Since Mr. Keep wishes to know a little more about finding the queen by the sifting process, page 703, Nov. 1, 1912, I will give some data from my 1911 foul-brood campaign, from which Mr. K. may draw his own conclusions. But by way of preface I will say that the beekeeper with some experience, who keeps Italian bees and uses loose-hanging frames, very seldom if ever needs to resort to any queen-finding device. The reader may wonder what a loose-hanging frame has to do with finding the queen. A great deal, as I will explain later on.

The device described by Mr. B. Keep, on the above-mentioned page, may give the desired result with the Hoffman or any other self-spaced frame; but it will not work so well with the loose-hanging frame. One serious objection to his *modus operandi* makes itself apparent at first sight.

His combs have to be shaken and brushed clear from bees (and queen) inside of the hive or on top of the frames, and this is one very unpleasant feature of Mr. K.'s plan, as all beekeepers who have had any experience in this particular work can testify. If it is done in the hive, bees are liable to be jammed or the queen injured; or if done on top of the frames, bees may fly over the edge of the hive, and who knows that the queen is not among them? Then the transferring of combs from the upper to the lower hive is not any too handy, although it can be done, if there is no alternative; but there is a better and quicker way.

I would now call Mr. K.'s attention to the accompanying drawing. It is just such a scene as I have caused and witnessed repeatedly during my foul-brood operations. This device, which I call "Greiner's queen-sieve" because the particular way of its

application originated with the writer, is simply a square piece of excluding zinc of proper size, with a little wing made of $\frac{1}{2}$ -inch lumber, on each side, to fit against the hive, and about half way down the stand. A little screw or nail on each lower corner, partly driven in, keeps it in place. It can be adjusted or detached in less than a minute. Its essential points are, first, large size to keep from clogging up; second, slanting position to assist bees in getting solid foothold; third, the hive with the attached sieve should be placed on the old accustomed stand, that the homecoming bees and those that take wing when the combs are being shaken may readily find their home.

When the queen is wanted, her hive is moved in front of the old stand, and the empty one set in its place. We then remove the outside comb on the opposite side; and with a shake or two and a brush or two all bees, even to the last one, are dropped close to the alighting-board of the old stand, after which the comb is placed also

on the opposite side of the empty hive. The same operation is repeated with all the combs; and when the old hive is stripped of its contents the new one has the combs in the same rotation they were before. In the mean time bees have begun to travel toward their accustomed home, and, in company with home-coming bees, are sifting through the excluder, where, sooner or later, the queen may be found.

Comparing this operation with Mr. K.'s plan I venture to say that it can be done in half the time. There is nothing to hinder the free handling of combs; shaking and brushing can be done in a hurry, transferring combs from one place to the other is the handiest imaginable, and the finding of the queen in open daylight much easier than to look for one in a bee-covered hive.

But there is another point that tallies on my side. While Mr. K. has to shake, brush,

and transfer every comb in the hive before he can begin to look for the queen, by my method I seldom have to go to that trouble. If the operator will keep his eyes on the bees on the ground, the chances are three out of four that he will see the queen drop when shaking off one or the other of the combs, frequently one of the middle ones. This accomplishes the object. He can pick her up, cage her, or dispose of her as circumstances may dictate. The rest of the combs, of course, need not be shaken off—simply transferred with the adhering bees from one hive to the other. It is needless to say that the excluder is removed as soon as the queen is found. Any bees remaining in the empty hive may be dumped with the rest in front of the old stand.

As I said before, the beekeeper with some experience hardly ever needs to resort to the use of the queen-sieve. Of the 45 or 46 diseased colonies, all blacks, from which I had to take the queens, about 40 I had caught and caged at different times, before I ever attempted any shaking-off operations without the use of the queen-sieve. The other five or six baffled my skill. In spite of repeated attempts I was unable to find them; and as a last resort the accompanying scene describes my final success.

Another instance where my method proved successful was away from home. Our bee-inspector had found at a neighboring amateur beekeeper's yard four diseased colonies, and had instructed the owner that he must either introduce Italian queens or annihilate his bees. In his consternation this beekeeper came to me, saying, "Mr. Greiner, I can send for the queens, and possibly introduce them; but I can not take out the old queens. Could you not spare the time to perform that little operation for me?" Then he added, "You know I use the Hoffman frame in my hives, and it is such a terrible job to manipulate them. I actually can not do it."

What could I do but promise?

A few days later, taking out (or, better, trying to take out) those four queens formed part of my day's program. I had no queen-sieve to fit his hives; but as I had been reasonably successful with my own bees I trusted to luck and proceeded without that commodity. The first hive I opened was comparatively new. Follower and frames were easily taken out, and I was fortunate enough to find the queen on one of the first combs. But not so with the other three. They were so stuck up and glued together that it seemed next to impossible to dissect them. When I finally did gain access to the combs the continued prying and jarring had aroused the bees

to such a state of nervousness that finding a queen was all out of the question. I left them that day.

The next day found me again at the same place; but this time my operating outfit included a properly constructed queen-sieve of the Greiner pattern. Although I opened the hives with the utmost care, and handled the combs with practically no jarring, I could not find the queen of any of the three hives. Necessity compelled me to use the sifter, which did the business to perfection. I picked one from the ground. The other I took from the excluder just after she had passed on to it, and the third one I never found. But as that colony accepted their new queen without any trouble she was probably killed or lost during the operation.

It will be noticed that the manipulation as described above reverses the position of the combs—that is, the fronts become backs, and the backs fronts. I have never noticed any detrimental result from the change; but if the operator feels anxious to retain their original position, the old hive, when removed, should not be changed end for end. The object of facing the hive toward the old stand is to assist the emerging bees, and there are always more or less investigating the disturbance in finding the old location.

Beekeeping Talks at the New York State College of Agriculture at Cornell

Six years ago the New York State College of Agriculture at Cornell instituted what is known as "Farmer's Week." The number of visitors is yearly increasing, over 2500 having registered last year. The college realizes that beekeeping is a fascinating subject to many people, and that bees are of vital importance to the farmer and fruit-grower. Therefore the management last year looked about for a capable man to present the subject of scientific beekeeping to the farmers who gather here for Farmer's Week. They were fortunate enough to secure Mr. S. D. House, of Camillus, N. Y., who is known by the readers of GLEANINGS to have a most enviable reputation as a producer of fancy comb honey. He gave several lectures on hives, manipulation, and the diseases of bees.

It was my good fortune to be able to attend a part of these meetings, and I assure you they were far from dull. Mr. House is an interesting speaker, and has the power of imparting to his audience something of the enthusiasm which is manifest in his every word and action.

WENDELL T. CARD.

How to Get the Greatest Yield of Honey from Sweet Clover

Just before sweet clover blooms, mow all on your own farm for hay and let the bees forage on your neighbors. Then when your neighbors' clover has gone to seed, yours will have grown up again and will yield nectar until freezing weather comes.

Heads of Grain from Different Fields

Another Hive-stand Suggestion

"Of the making of hive-stands there is no end." The quotation is not strictly correct, but it suits the case. And yet, after all, there is a want of hive-stands, judging by the makeshifts so commonly to be seen. As bees take to hollow trees, wall spaces in badly kept buildings, and any place regardless of appearance, the opinion seems to be general that any old thing is good enough for bees. The bee-keeper betrays his careless methods by the appearance of his hives and their supports. The conditions are often distressing to see. All will agree that convenience in handling and easy access to all sides of the hive are prime requirements for a good hive-stand.

Cheapness should come next. Having cheapness easily within reach, permanence is not so important. Then the simpler the construction and the cheaper, and the less material used, the nearer one comes to an ideal stand, having regard for efficiency.

The stand which I use and will now describe is the result of circumstances. Having a lot of odds and ends of 2 x 4's from repairing grape-arbors and trellis work, it occurred to me to use some for a temporary hive-stand which was needed on short notice. The thing answered the purpose so well, it is so simple, and so easily made from material which otherwise would be wasted, and is so durable that I have since used no other.

Cut two pieces of 2 x 4 or 3 x 4, each 20 inches long; also cut two pieces of 1 x 2, or any width available, each also 20 inches long. Lay the 2 x 4's on the bench or floor, on edge, 16 in. apart, outside to outside. Crosswise upon these lay the inch strips, also 16 in. outside to outside. Tack at each bearing with a three-inch wire nail; then make every thing square, and drive the first nails home, putting an additional nail in each bearing.

The hive is set parallel with the inch strips so that the foot can be placed partly under the hive when lifting the hive-body or supers. This stand raises the bottom-board 5 inches from the ground, which meets all conditions in this part of Jersey, where the soil is not particularly sandy nor wet. The 2 x 4 pieces may be soaked in creosote oil some time before being put under the hive. This will help to preserve the wood, and will repel ants for some time.

B. KEEP.

Finding Black or Dark Colored Queens

As I bought a lot of bees last June, mostly hybrids, I usually have poor luck in finding black queens. I ordered two dozen Italian queens to be delivered by September 1, but didn't get them until a week or ten days later. By that time the lower body or hive was well filled with honey, and I always have my colonies strong in bees. The weather then was extremely warm, and some queens were dead on their arrival. Some more died the next day, and I had them in the most suitable place I could find. Wherever the bees looked bad and lifeless I took them all out, and in their place I put young bees only. It takes me from one to three hours, as a rule, to find black queens, but not so with the Italians. I can find them on an average in from thirty minutes to an hour, usually in less time—that is, when the hives are crowded with bees.

So I figured out a plan whereby I could find them more quickly. I had to get them introduced, because it was getting so late the weather might turn cold or rainy, any time. Robbing had started too. I use a cage, but prefer working in the open.

I moved the hive into which I was going to introduce the Italian queen, to one side. In its place I set an empty hive-body with two old combs or good ones. It is a good plan to use dry combs, for the bees will not stay on them so much.

I shook all the bees in front of the empty hive, then put on an excluder, and on top of that I set the super with the combs, all except one from which the bees had been shaken. I use the cages for introducing that press into the comb. With one comb out I had room enough to put in my cage with queen. In about two days I took off the upper super. It has been my experience since that I nearly always find my dark queens. With but few bees below, the queen is easily found or else is missing. By that time the introduced queen is nearly always gnawed out, or, when released, would be accepted. I have never had a particle of trouble, and have never lost a queen by this method. Besides, it is easy, and is a much quicker method of introducing queens of the dark strain of bees.

EDWIN A. KRINKE.

The Control of After-swarms; First Cell Likely to Hatch on the Ninth Day from the Time the Prime Swarm Issues

On page 387, June 1, A. B. Anthony says, "We have by the 'wing-clipping method' a decided aid in the handling of primary swarms; but it is the after-swarms that not only can and do make us climb, but that sometimes beat us completely; and it would not hurt a bit if one more slat could be added to the knowledge our older veterans have given us on the handling of this problem."

I do not know that I shall be able to add the "slat" desired, but will give my method of controlling after-swarms, whether I practice the "wing-clipping method" or make increase by a modified Alexander method. In addition to my book-record I keep a record on a thin piece of board of the number, the date of casting the swarm, and when the queen is due to hatch. I count to the ninth day after the swarm issues as the day the cells are due to hatch. That is, the forenoon of the ninth day after the first swarm in an apiary issues, a young queen is quite likely to be hatched. But after the first one, the swarms may issue before the first queen-cell is capped, and so it may be a day or two or even more before a queen is hatched. My method is to look into the hive the forenoon or early in the afternoon of the ninth day; and if I find a queen-cell from which a queen has hatched I find the queen and then endeavor to cut out all remaining queen-cells, and finally put on a super of sections. Some-

times the cap on a queen-cell will close back so that it will require close observing to notice that a queen has hatched.

If, in examining a hive on the ninth day, I do not find that a queen is hatched, I place an empty hive by the side of the one examined, and put therein all the combs containing queen-cells except a frame containing but one cell. If I find a frame with but one good ripe cell I use it; but if I do not so find I remove all the cells but one good one from a frame and put this frame and all others that do not contain queen-cells back into the hive and put a follower board up against the frames. I make sure there is but one cell in the hive, as it may after-swarm, for many bees will leave the hive beside and return to this one. So far it has made no difference how many cells are in the hive at the side; there has been no after-swarming. In a day or two, or three, look; and if a queen has hatched in the hive at the side, cut out all the remaining cells and put all the frames back into the first hive and put on sections.

If it is desired to form a nucleus from some good colony, or if a queen from some good colony is wanted for any purpose, here is an opportunity. If it is desired to save a queen or so from some good colony the separation had better be made a day sooner, as the first queen may hatch and destroy all remaining cells. While cutting out queen-cells, sometimes one or more queens will hatch; and if they are from good stock cage them and take to some of poorer stock; or if there are none such, to some others that are due to hatch or will be in a day or so; and first gently puff in at the entrance a little smoke and then let the queen go in and then puff in a little more smoke. By this method newly hatched queens are quite likely to be accepted. Then in half an hour or so, or when convenient, look into these hives and find the queen; and if she has been accepted, cut out all cells and put on sections.

If the weather has been unfavorable for swarming for a day or so, and then swarms issue, it might be well to examine on the eighth day, or even earlier. In the management of bees there are so many things modified by conditions that such conditions should always be considered. Do not think that I always succeed in finding all queen-cells, for sometimes some are missed, and so an after-swarm sometimes issues. When such occurs I take my small light hiving-box on a light pole, and, often standing on the ground, or sometimes on a light ladder arranged as an easel, I reach the box up against the cluster and jar them from the limb; and when they enter the box I carry them to the hive from which they came and lay the box in front until I cut out the overlooked cell, and then pour and shake the bees from the box and they enter the hive. By this method I seldom have to do any climbing; and if I do, it is but little, as with my light hiving-box and light pole I can reach quite a distance. This method for me is quite satisfactory.

Sending Bees in Car Lots; Importance of Water

I sold a car of bees to D. B. Husperger and Chas. D. Case at Ordway, Colo., and will send you their letters, and should like to have your comment on them and the shipment, and state how well or ill we succeeded.

Fisher, Ark., June 18.

S. J. ALEXANDER.

[We judge that you were fairly successful, but infer there was considerable loss of dead bees and unsealed larvae and eggs on the way. This last loss could have been avoided if you had used water to spray the bees on the way. In GLEANINGS for June 15, 1912, page 371, you will find an article on our experience in shipping bees. You will note that we emphasize the importance of using plenty of water and spraying the bees as often as may be required. We also took the precaution to have wire cloth at top and bottom. A colony of bees or nucleus must not have too many bees in it to go through well.

Therefore, our colonies are somewhat light when they are shipped from the South to the North. A strong colony will not go any great distance in a car that way without considerable loss en route. If you ship any more bees, take the precaution to have wire cloth at top and bottom, and a barrel of water in the car, with a proper spraying-outfit, so that you can wet down the colonies along the journey, or as often as the bees require it, and they will need it, if the weather is warm, several times a day.—ED.]

How to Introduce Virgin Queens; Best Age for Introducing

Would it be all right to introduce virgin queens to colonies of black bees right from the nursery cage without having nuclei?

Grant, Ont., June 24. JOHN MACDOUGALL, JR.

[It will be all right to introduce a virgin queen to colonies of black bees right from the nursery cages. But such virgins must not be more than a day old, and it would be very much better if they were not more than two or three hours old. A virgin queen that is three, four, five, or six days old is pretty sure to be attacked by the bees and killed. It is also advisable to let the virgins run in at the entrance; and be careful that you don't handle them with your fingers, otherwise the odor acquired from your own person is liable to be communicated to the queen, with the result that the bees will attack her. Queens should be released and allowed to run into the hives as quietly as possible.

Be sure that the black colony is absolutely queenless, and that there are no cells in the hive. The surest way is to make the black colony queenless, and then from twelve to twenty-four hours afterward let a virgin queen run in at the entrance, being careful not to cause any disturbance.—ED.]

Putting Bees in Twin Mating Nuclei

I am anxious to get my twin boxes into operation and would like to know whether in your experience it is possible simply to take the boxes and put in a good dipper of bees along with a young virgin just hatched, omitting the move of getting little frames filled with brood in larger hives first. You understand they are, of course, all nicely drawn out from last season's work.

H. HARLEY SELWYN.

Kirk's Ferry, Quebec, Ca., June 13.

[The plan of filling the baby nuclei by means of a little dipper on combs adapted to those boxes is perfectly feasible, and the one that we regularly employ. Originally, it was our idea to put these little frames into the larger Langstroth frame—three of them to a frame—get them filled with brood and honey, then take them out and put them in the baby nuclei; but we find that is not necessary. We cut combs out from old standard-size combs, slip them into the baby frames, insert the frames in the hive, and then dump in about a third of a pound of bees. If the combs contain no honey, of course the bees will require to be fed.

You will find this method described in our A B C and X Y Z of Bee Culture in the edition for 1910 and again in the edition for 1913. You will also find it in GLEANINGS, Nov. 1, 1909.—ED.]

Stopping a Case of Robbing After it is Once Started

I have found a sure remedy for prevention of robbing. Remove the bee-escape from an escape-board, and put a piece of excluding zinc over the hole. Place the colony that is being robbed on top of the escape-board, and a hive with a set of empty combs beneath. Leave the colony on the old stand. If the bees have a queen and are in normal condition I have never known this plan to fail. The robbers don't seem to dare to go through the zinc.

Brush, Colo., Feb. 7.

DANIEL DANIELSON.

Our Homes

A. I. ROOT

"Thy kingdom come; thy will be done on earth as it is done in heaven."

Our readers will recall that I have for some time past been declaring that some great "world-wide" event is just before us. We have wireless telegraphy, flying-machines, telephones, and progress and improvement everywhere; but of course the progress is not *always* on the side of righteousness; but we have God's promise that his "kingdom" shall ultimately prevail. When I asked the question, "What is coming next?" a good brother away off in California said *he* could tell me what the great thing was to be very soon on the world's program. He said *Jesus Christ* is coming back to earth; and I think he was right about it, and I think our business is to be on hand and on the alert and ready for "his coming."

With the above in mind you may understand how greedily I drank in the sermon I am giving below. Of course I sat close to our good pastor, as I am obliged to do with any speaker on account of my deafness; and I said "amen!" to his different points so many times that I was ashamed to say it any more; but some of the audience afterward expressed a wonder that I did not keep on with my amens.

Now, if any of you good people feel inclined to shout amen as you go over the sermon below, just put your amen on a postal card (or any thing else you like), and direct it to your old friend A. I. Root.

THE MOVEMENT IN THE MULBERRY TREES.

BY REV. H. SAMUEL FRITSCH, D. D.

And let it be, when thou hearest the sound of a going in the tops of the mulberry trees, that thou shalt bestir thyself; for then shall the Lord go out before thee, to smite the host of the Philistines.—II. SAM. 5:24.

Saul, the ill-fated king of Israel, was dead. David, by divine favor and native ability, had assumed the dead monarch's idle scepter and ascended his vacant throne. All Israel was jubilant, except for one thing—the Philistines, the uncircumcised Philistines!

When the Philistines heard that they had anointed David king over Israel, they all came up to seek David. For reasons of his own, David was not very anxious to see the Philistines, so he went down to his stronghold, leaving orders to say when they called, "Sorry, but not at home!" But the Philistines were not to be put off as easily as all that. They had an intense desire to see this David, so they prepared to sit down and wait for him. They gathered their

forces together in the valley near by, ready for battle.

In this predicament David enquired of the Lord, "Shall I go up against the Philistines? Wilt thou deliver them into mine hand?" and the oracle gave him this assuring reply, "Go up: for I will certainly deliver the Philistines into thine hand." And David went up, and smote the Philistines.

But these Philistines, though uncircumcised, were nevertheless brave men. They rallied their scattered forces, came back, and again pitched their tents in battle array.

Again, therefore, David enquired of the Lord: "Shall I go up against the Philistines? Wilt thou deliver them again into mine hand?" But this time the answer of the oracle was, "Thou shalt not go up; but circle over to that grove of mulberry trees yonder, and let it be, when thou hearest the sound of a going in the tops of the mulberry trees, that then thou shalt bestir thyself; for then shall the Lord go out before thee, to smite the host of the Philistines."

Accordingly, David camps his men in the mulberry grove. He waits, breathlessly watching the tops of the trees. Not a branch waves, not a twig shakes, not a leaf trembles, not a sound, not a sign! And yonder is the army of the Philistines, every minute adding greater numbers, every hour becoming more formidable!

It must have been nerve-racking and discouraging for David and his men thus to wait in the strange stillness while every moment the enemy became more powerful and insolent. Sometimes earnest Christians to-day become impatient and disheartened because great evils flourish in the land like the green bay tree, while all around there seems to be a stupefying moral and religious lethargy and apathy which cares not and does nothing! How long, O Lord, how long? How long must we tamely sit by and submit to the insolence of the liquor traffic, the burning shame of the white-slave trade, the stigma of ecclesiastical controversy and competition, the cry of industrial oppression, the stench of political corruption, the wicked waste of war? Will the kingdom never come?

It is my purpose in this sermon to call your attention to certain movements in the tops of the mulberry trees of our land and time which seem to me to be prophetic. The kingdom *is coming!* The Philistines are soon to be routed and smitten hip and thigh! I know it! I know it! I know it

by the rustle in the tops of the mulberry trees!

1. There is a rustle which sounds very much like the coming of a great *moral movement*. Take the temperance movement as an example. It is not so very long ago that to alcoholic beverages there was universally ascribed a practical food value. The German nation, for instance, has been pointing with pride at her stalwart and brainy sons, saying, "Beer!" But now the emperor dares to intimate that the stalwartness and intellectuality of the sons of the Fatherland exist, not *because* of beer but in *spite* of beer, and he warns the young men of the nation that alcohol will rob their brains of their clearness, their nerves of their steadiness, and their muscles of their vitality, and urges the members of the army and navy to join total-abstinence societies.

Until very recently wine was considered an absolute necessity at high social functions. True, for some time it has been allowed good form for a guest to refuse wine at a banquet if his host provided it; but it has not been considered permissible for a host to refuse to set up the wine if he knew his guests expected it. But now comes Secretary of State Bryan and blandly pours the grape juice, and establishes recognition for that which had not been accorded recognition before—the conscience of the host. And the significant fact is that the people of the country are applauding our new grape-juice diplomacy!

Until very recently it was believed that a man to be popular enough to be elected to high office must be a hail fellow well met, a jolly good soul who would clink the glass and drink the lager. But now things have come to such a pass that an ex-president of the United States considers it worth while to refute in libel court the charge that he drinks to excess. We rejoice in Col. Roosevelt's vindication; but of even greater consequence than the personal vindication of a prominent public character is the significance of the recent libel suit as a reflection of the public conscience and an indication of what the people now expect of their political leaders. There was a time when the rumor that a man was a drinker would have worked to his political advantage rather than damage. But the fact that such a prominent political figure as Roosevelt considered it necessary to refute the charge that he drank to excess shows to what an extent the liquor has been squeezed out of politics. It means that henceforth no man will dare to run for high office who has the slightest taint of whisky on his breath.

For many years the national prohibition of the liquor traffic has been regarded as a

consummation devoutly to be wished, but altogether too improbable and impracticable and remote a proposition to be given serious consideration. But just a few days ago there came in my mail a circular from the Anti-saloon League entitled "The Next and Final Step," the purport of which is expressed in this sentence: "We believe the time is fully ripe for the launching of a campaign for national prohibition—not by any party or parties, but by the people." The circular supports its proposition by calling attention to four facts: 1. The people are on to the real character of the traffic. "It no longer has advocates; it must depend for its existence upon partisans." 2. The nation is aroused as to the grave peril we face. "The saloon stands for the worst in political life." 3. What has already been accomplished is prophetic of what can be accomplished. 4. The opportune time is here. To quote from the circular:

"The time for a nation-wide movement to outlaw the drink traffic is auspicious. Organization is now established and in operation in all parts of the country. The forces that definitely oppose the traffic are in accord as at no time in the past. The moral, scientific, and commercial aspects of the problem are being more intelligently put before the public than hitherto. The narrow, acrimonious, and emotional appeal is giving way to a rational, determined conviction that the traffic being the source of so much evil and economic waste and the enemy of so much good has no rightful place in our modern civilization."

But I am not preaching a temperance sermon this morning. I have simply used the present status of the temperance movement to illustrate that there is something stirring in the tops of the mulberry trees which is indicative of an immediate moral reform. The same change that I have indicated in the matter of temperance may be noted in every phase of the moral problem. Cities are appointing vice commissions to study how to abolish the shame of the social vice. The government is appointing investigating committees to look into graft, corruption, bribery, and lobbying. Chambers of Commerce and Boards of Trade are studying how to cure strikes, riots, boycotts, industrial and economic oppression. Is the kingdom coming? Of course it is coming! You can tell it by the moral movements in the tops of the mulberry trees!

2. There is a rustle in the tops of the mulberry trees which sounds very much like the coming of a great *ecclesiastical movement*.

The curse of Protestantism is denominationalism; but it is only within very recent years that we have begun to recognize it as a curse. There are many things about Catholicism that you and I do not like; but

let it be said to the eternal praise of the Roman Catholic half of Christendom that it stuck together; and it must be said to the eternal shame of the Protestant half that it has divided and subdivided until it has resulted in the very pulverization of the body of Christ. The United States Census recognizes over 150 denominations, among whom there are 14 different kinds of Baptists, 17 different styles of Lutherans, and 17 different brands of Methodists! Verily, denominationalism has run riot and wrought havoc!

In the history of denominationalism we may trace six distinct stages.

First, separation. Whenever a man got a new theological idea or a unique religious experience, he felt called upon to start a new denomination. It never seemed to occur to the leaders in those days that the thing to do was to stay in the mother church and bring the new idea to the church and the unique experience to its members. The whole trend was separation.

The second stage was condemnation. Each denomination said, "I am absolutely right, all the rest are unconditionally wrong." The churches actually "hated one another for the love of God." Christendom was divided into "Christian" and "Heretics," and no one was counted a good "Christian" who had not slain his "Heretic." The usual denominational consciousness expressed itself thus: "The members of my denomination are Christians, all other denominations are heretics."

The third stage was competition. Churches stood on opposite sides of the street competing in unholy rivalry for the converts of the community. This stage was aptly illustrated some summers ago in the city of Lincoln, Neb., when the congregation of the Presbyterian church sang, "Will there be any stars, any stars in my crown?" while at the same moment the Methodist church across the street was singing, "No, not one, no, not one!"

The next stage was toleration. The churches did not quarrel, but they let each other strictly alone. "You in your small corner, and I in mine"—but don't you dare get near my corner!

The next stage, in which we find ourselves at the present time, is federation. The churches are working together for the common good, shouldering together the burdens of common problems. This is not only true in communities locally, but even more so in the country at large. The Federal Council of the Churches of Christ in America includes 32 Protestant denominations, and represents a church membership of no less than 20,000,000.

What is the next step? Combination. Are there any rustlings in the tops of the ecclesiastical mulberry trees showing that combination is a near possibility and probability? There certainly are! In every great religious gathering they are discussing church union. The Episcopal church—mind you, not the Congregational church, but the Episcopal church—is making serious arrangements for a world conference on faith and order, looking toward a union of all Protestant bodies. At the general convention of the Protestant Episcopal Church in the United States of America in 1910, the following resolution was adopted:

"Whereas, There is to-day among all Christian people a growing desire for the fulfilment of our Lord's prayer that all his disciples may be one; that the world may believe that God has sent him:

Resolved, That a joint commission be appointed to bring about a conference for the consideration of questions touching faith and order, and that all Christian communions throughout the world which confess our Lord Jesus Christ as God and Savior be asked to unite with us in arranging for and conducting such a conference. The commission shall consist of seven bishops, appointed by the chairman of the House of Bishops, and seven presbyters and seven laymen, appointed by the president of the House of Deputies, and shall have power to add to this number and to fill any vacancies occurring before the next general convention."

With the Episcopalians taking the lead in such a world conference, who will dare to say that there is not a movement in the mulberry trees which betokens the coming of actual church union?

3. There is another rustle in the tops of the world's mulberry trees which sounds very much like the coming of a *universal peace movement*.

It is not so very long ago that war was regarded as a permanent and prominent factor in civilization, when the war-business was deemed the only really heroic calling, and the war-path the only path that leads to fame.

It is only a few years ago that the great German militarist, Von Moltke, wrote: "A perpetual peace is a dream, and not even a beautiful dream. War is one of the elements of order in the world established by God. The noblest virtues of man are developed therein. Without war the world would degenerate and disappear in a morass of materialism."

It is only a few years ago that another officer of the German army argued: "Deer and antelope thrive best where there are lions and tigers to kill them; civilization gets forward fastest on a powder-cart, and enduring world-wide peace would mean degeneracy and be a misfortune for the human race."

It is only a few years ago that the public mind and conscience quite generally ac-

quiesced in such sentiments as these. But the last few years have seen a decided and significant change in the public conscience regarding war.

There is less talk about the glory of war, and more recognition of the brutality of war. What glory is there in human beings created in the image of God killing each other?

There is less talk about the benefits of war, and a more serious consideration of the cost of war. The nations of Europe in time of peace have each year a war expense of \$2,000,000,000—in time of *peace*—think what the expense would be in time of actual war! Men are beginning to calculate the untold good that could be done to humanity if all this money were spent for bettering the condition of the people.

There is less talk about war as the last resort of disputing nations, and in its place there has grown up a vocabulary with such terms as "The Hague Tribunal," "The Interparliamentary Union," "The International Court of Arbitral Justice," "The Supreme Court of the World," "The World Peace Foundation," "The American Association for International Conciliation."

Yes, there is a war-movement in the tops of the mulberry trees, only it is blowing in the opposite direction from what it did in David's day. Then it blew toward war, now it blows away from war.

There are other movements besides the three that I have mentioned, more comprehensive, perhaps, such as the social movement; but these three are typical of those general tendencies of the day which show to the discerning mind that God is answering the age-old prayer of his people, "Thy kingdom come."

"And let it be, when thou hearest the sound of a going in the tops of the mulberry trees, that thou shalt bestir thyself." "We are living, we are dwelling in a grand and awful time!" The kingdom is coming! You can tell it by the moral, ecclesiastical, national, and social movements in the tops of the mulberry trees! Movements to banish evils from the land! Movements to bring together the divided parts of Christendom! Movements to bring the blessing of world peace! Movements to make the kingdom come!

God grant that this morning as we list to the sound of the going in the tops of the mulberry trees we may take new heart and new courage, knowing that God is still working his wonders to perform, and, above all, may it be that, when we hear the strange rustling, we will all bestir ourselves!

SHALL WE OBSERVE SATURDAY OR SUNDAY?

I have been a subscriber of your bee journal for nearly a year, and have read nearly all your Bible texts. I do like to read them, and I agree with you on the most of your writing except on the fourth commandment. You say the first day is the sabbath, and the Bible tells us that the seventh day is the sabbath. The fourth commandment tells us that we should remember the sabbath day. "Six days shalt thou labor, and do all thy work; but the seventh day is the sabbath of the Lord thy God. In it thou shalt not do any work." And it tells us that the Lord blessed the sabbath day and hallowed it. Can you say any thing like that about the first day of the week, or the man-made Sunday?

Dear River, Minn., Nov. 8. H. A. GRUND.

Our older readers will remember that for forty years past I have, every little while, stopped to consider the matter which is again brought up in the above letter; and may God give me grace and wisdom while I try to explain to this good brother and a lot of other near and dear friends why it seems to me no good can be accomplished by changing our present Sunday to Saturday. I think I am pretty well posted in the matter, for my brother's wife, where she lived, was an earnest advocate of having Sunday on Saturday.

First and foremost, when it is Sunday here, on the opposite side of the world (or in opposite parts of the world) it is some other day of the week; and there are islands in the sea where the question has never been settled as to what day of the week it is. This dividing line is 180 degrees east of London, or through the islands near New Zealand; and it is literally true that next-door neighbors have Saturday on one side of the yard and the other one has Sunday at the same instant. What the day of the week is can not be settled. If you go around the world by traveling east, some other day will be Sunday than if you went around the world by going west. I think you will get my idea. Well, in view of the fact that the days of the week are whatever the people happen to decide on, what sense or science is there in thinking the world would be made better by having every thing as now established out of joint by the change proposed? I have submitted the matter in this way perhaps a dozen times since GLEANINGS was started, and no advocate of this change, so far, has ever been able to refute it. It is true one good brother did say something like this: "Mr. Root, if you and I were traveling we would both be able to decide which day was Saturday and which was Sunday." To this I agreed; but we would have to be guided even then by the customs of the people wherever we happened to stop.

I have sometimes made the suggestion to these good friends that, instead of undertaking any such change as they propose,

we should simply agree to call *Monday* the first day of the week; and it is in reality the first working day. Then every thing would be lovely. But the friend to whom I proposed this solution of the difficulty simply replied, "Because the Seventh-day people will not have it so." We are having a hard time, God knows, to preserve the sanctity of the generally accepted Christian sabbath. In view of this, is it not a little sad, to put it mildly, to think so many good people should try to weaken our forces for righteousness by something so comparatively unimportant? Just now, in this day and age of the world, good people are dropping minor differences in order that we may work together to bring about the glad time when God's kingdom shall come and his will be done on earth as it is done in heaven. United, we stand; divided, we fall.

So far as I can see, and I have examined the passages from the Bible carefully that have been pointed out to me, the Bible nowhere attempts to fix the day of the week. In fact, it could not do so. It does plainly command, however, that one day in seven shall be remembered and kept holy, leaving the people to decide for themselves what day shall be called the first day, and what day shall be generally recognized as the seventh.

REMEMBER THE SABBATH DAY, ETC.

Mr. Root.—For more than thirty years I have been interested in your writings on home topics and the moral questions of the day, and was well pleased with what you say about the sabbath in *GLEANS* for Jan. 15. I think we need to emphasize the duty of Christians to prepare for the sabbath by doing on Saturday what can reasonably be done of the work, such as chopping wood, etc., which, if left, would be necessary labor on Sunday.

THE GERMAZONE SWINDLE.

I am glad you have told us what a simple and cheap remedy germazone is (p. 785, Dec. 1). I have used it for nearly ten years, and find it a splendid remedy for roup and bowel trouble; and, when used with chloride of lime, it is good for the treatment of canker, which resembles diphtheria, and is even worse to combat than roup. The price I paid was exorbitant, yet I suppose I should have failed to get the benefit of it if my attention had not been called to it by an advertisement.

TEMPERATURE; VARIATIONS IN THE SAME LOCALITY, ETC.

I have been reading your remarks on temperature, page 70, Jan. 15. On the coldest night of the present winter, our thermometer, a minimum-registering instrument which has proved quite reliable during nearly twenty years, was at the north side of the house, but in a somewhat sheltered location, and registered 3 above zero. In and around the town of Alamagordo, about seven miles away, temperatures reported varied from 8 below to 21 below zero. The government thermometer, near town, recorded 14 below. I can readily believe all of these temperatures to be approximately correct, and I base the opinion on the following incident: Something like forty years ago, in Iowa, I looked at the thermometer before sunrise, and it stood at 40. On go-

ing a little beyond the stables, on a side-hill facing the west, and only about thirty rods from the house, I saw frost on the grass. I returned to the house and laid the thermometer in the grass near by, but it still remained at 40. I then took it to the side-hill and laid it down in the frosty grass, when it quickly dropped to 30. In the case of the varying temperatures at Alamagordo, the currents of air from the canyons in the mountains near by might have caused the difference.

A FEW WORDS ABOUT HAWKS, ETC.

It is pretty expensive waiting for each individual hawk to "acquire the habit" of catching chickens when one has chickens worth from one to five dollars each; and nearly all kinds will catch chickens sometimes, and song birds often. I seldom disturb harriers, though even *they* sometimes get a chicken. I have seen a pigeon hawk (or, rather, a sharp-shinned hawk, which is practically the same) pick a robin, larger than himself, from the top of a post, and easily fly with it 25 or 30 rods to a sheltered place in a grove where I soon dispatched him; but he had killed the bird. In Iowa, Harlan's hawk, a very large species, seldom troubles chickens; but in Virginia they are very destructive.

BURDETT HASSETT.

Alamagordo, N. Mex., Feb. 4.

Let me add one thing more about temperature. There may be quite a variation in a very short space of time. Years ago I was one night undecided about whether to call up the help and put the sashes on the cold-frames, etc. I was on the watch long before daylight; but when the sun was up, and no damage, I breathed easier and went to breakfast; but frost came so as to do quite a little harm in spots *after* the sun had been up a full half-hour. I hope all will "take notice" again that the germazone sold at 50 cts. a bottle is less than one cent's worth of permanganate of potash, with a little alum added. What do you think of the man (or poultry editor) who would consent to be a party to such a transaction?

A PLAINTIVE LETTER FROM A BROTHER BEEKEEPER WHO IS "BEHIND THE IRON BARS."

The letter below came during my absence in Florida. Along with it was quite an interesting protest against our government for being a party in the liquor business. The letter was rather long, and several things our friend urged at the time have since come to pass, so we give only the closing paragraph as follows:

Mr. Root.—I beg your pardon for writing to you without an introduction; but knowing as well as I do the curse of whisky I have taken this liberty. I am, perhaps, only a convict; but if a word of mine will help to prevent any young man or girl from traveling the same road whisky has taken me, gladly will I speak that word. I had a Christian father and mother. Whisky separated me from them; a good Christian sister—whisky parted me from her. I was respected by many friends, but whisky took the respect from me, and left me—what? Why, nothing but a prison; and yet after all it may be all

for the best that I came here when I did. I am but twenty-five years old. I see where I have made mistakes, and I intend to turn those same mistakes into future profit by not making them again.

Asking your pardon for this long letter, I beg to remain yours truly until prohibition really prohibits.
Pittsburgh, Pa. A7361, N. S.

Permit me to say, dear brother, I looked over the letter above with careful scrutiny

to find some place where you recognize the importance in a crisis like this of *divine help*; and although you do not close by asking the readers of GLEANINGS to pray for you, I am going to ask our good friends to remember our unfortunate brother who is in trouble, even yet, inside of prison walls.

Poultry Department

RHODE ISLAND REDS AND MOVING THEM TO ANOTHER NEST WHEN THEY WANT TO SIT.

Mr. Root:—In the May 1st issue of GLEANINGS, page 321, I am a little surprised at the remark of your correspondent in regard to the Rhode Island Red pullets not sitting when removed from one nest to another. My flock is composed mostly of Rhode Island Reds; and out of 25 sitting hens and pullets I have been compelled to move 24, and some of them quite long distances, and not one has refused to sit. With the mixed Leghorns and Plymouth Rocks I have not been so successful.

Now in regard to my management of sitting hens. I have a sitting-room screened off with chicken wire and burlap—formerly bran and chop sacks—from one of the hen-houses, and in this room I place just as many individual nests as I have hens ready to sit. I place in each of these nests two eggs—not porcelain nor rotten eggs, but good ones. After dark I take my hens gently from their nests, one at a time, and carry them in my arm in the same position in which they were sitting, put them on the new nests, and shut them on the nests. In this room I place vessels containing water, feed, grit, and a dust-box. In the afternoon of the following day I let the hens off to eat; and when I am doing up the evening work I slip my hand under them, take out the two eggs and lay before and around them thirteen or fifteen eggs. This is done in daylight; and by the time I have finished up my other evening work around the chicken-yard, and go in to see how they are getting along, they will have all the eggs rolled under and be hovering them very contentedly.

This plan is much more simple and satisfactory than my incubator experience, for all I have to do is to see that they have plenty of feed and water, and look in two or three times a day when other duties call me to the hen-house, to see that no two hens are sitting on the same nest—a very rare occurrence, and never with the Rhode Island Reds.

There is only one drawback to this plan, and that is when the hens are set at different times, and the first sittings begin to hatch. At this time some of the other hens are liable to get excited and want to help mother the chickens when the chickens are very noisy, and sometimes it becomes necessary to remove the hatching hens; but as the nests are made single, it is very easy to pick up the nest and carefully carry it to some other building.

Fayetteville, Ark., May 26. MISS C. E. JORDAN.

My good friend, I am very glad to get the above; and that is about the way the Rhode Island sitting hens behave here in the North. But when I went over to neighbor Rood's and asked him if he had any sitting hens, he replied, "Yes, plenty of them; but I fear they will not *continue* to sit if you move them to some other nest—at least they will not with me. But perhaps they will work better with an experienced man (?) like yourself." Well, I went and

got three, off the nests, that seemed fully determined to sit; but they were all off the notion when they got over to my premises, in spite of putting boxes over the hens, nests and all. I wish to say to their credit, however, that all three raised nice broods after a laying of eggs; and, best of all, *all three* commenced laying again when the chickens were about three weeks old. Now you say, my friend, you shut them on their nests; but you do not tell exactly how, but I infer you put some sort of box over them so as to keep them in the dark, as you say further along that your nests were all made single.

GROUND MUSTARD FOR CHICKENS.

Some time last winter I saw an advertisement in one of our poultry journals of the R. T. French Co., of Rochester, N. Y. Their principal business seems to be putting up mustard for the whole wide world, chickens included. After some correspondence I ordered a barrel at 18 cts. per lb., laid down at Bradentown, Fla. When the package was unloaded from the steamer it was so badly broken that the transportation company went and got a new barrel to hold it. They told me there was quite a lot of sneezing, and wiping of eyes, before they got the "stuff" transferred. Permit me to say here that the French Co. made good all the loss of mustard, taking the task off my own hands of settling with the railroad company.

Two things prevented my giving the mustard a fair test with my flock of forty or fifty chickens. First, it was near time to go north. Second, I had been feeding them for a month or more with Conkey's "laying tonic," so they had been giving me 35 or 40 eggs from 60 laying hens. I think you will agree with me that it would be pretty hard to make an improvement under such circumstances with mustard or any thing else. Not so, however, with the Indian Runner ducks. Eighteen laying ducks had been giving fourteen or fifteen eggs nearly all winter; but about two weeks before the receipt of my mustard they had for some reason gone down to ten or eleven eggs. Within three days, possibly four,

after I began putting mustard in their mash I got 17 eggs from 18 ducks. The ground mustard was so strong that Mrs. Root put some of it on the table, and it seemed to answer every purpose of the high-priced mustard we get in little tin cans at the grocery. As the barrel of mustard was quite a spell on the way it did not reach us in time to give it a long trial before we went north. I used it in the wet mash with chicks of all ages, and they were very greedy for it, and it seemed to do them good. I did not bring any of the mustard here to Medina, because I do not get time while here to do very much with chickens.

A great many of the friends have been inquiring how much mustard should be given, say to a dozen fowls every day. Now,

I have not their directions at hand, but my impression is that we used a tablespoonful for each dozen fowls in their mash once a day. The mash we used was about equal parts of bran and middlings, sometimes adding Indian meal. The mustard is thoroughly stirred into the bran and middlings before adding water; then add just enough to make it crumbly, not wet. The amount suggested makes it taste pretty strongly of mustard; but the fowls do not seem to mind it. In fact, they will eat greedily green mustard growing in the garden when it is so pungent that even a little bit of leaf chewed up you will find about all you can stand. As the fowls seem to crave all such pungent green stuff, I am inclined to think that mustard must be good for them.

Temperance

THE CRISIS IS COMING.

Slavery was not abolished without bloodshed, and it has been frequently remarked that there will probably be bloodshed before the liquor business is in a like manner banished from our land. In the *Baltimore Evening Sun* for June 21 we note that W. H. Anderson, superintendent of the Baltimore Anti-saloon League, was assaulted in his office by Robert L. Ulman, son of a former whisky-distiller. Young Ulman commenced the assault with a "dog whip;" but Anderson, who is a big man (in several ways) took the whip away from his assailant, choked him into submission (but did not strike a blow), and then let up on his promise of good behavior. The reporter asked him if he was going to nurse his right eye on the morrow. He replied, "No. I am going to preach to-morrow morning at the Mount Royal Methodist Protestant Church, and I'll take the black eye right up in the pulpit."

Here is the letter that Mr. Anderson wrote that so incensed the liquor-dealer's son. What do you think of it?

Before long, when a brewer buys an automobile, people will figure how many children were robbed of carfare to the parks before the price of the auto filtered to him in profits. When some distiller contributes to charity, or builds a church, or finances some similar enterprise, folks will begin to wonder how many men were robbed of the hope of heaven by the stuff which he sold for profit, knowing it to be injurious, to enable him to pose as a generous patron of the church. When the wife of some distiller or wholesale liquor-dealer or prominent grocer who makes a specialty of liquor blossoms out in a diamond necklace at the theater, the margins of programs may be covered with calculations of how many children and mothers have gone without decent clothes in order that she may shine resplendent. And the day is not far distant when the socially prominent wife of a man who has made his money out of the liquor-traffic, upon giving some lavish entertainment in a palatial home, will find that even

the guests will involuntarily trace the connections between that luxury and the hovels in the slums, and the pitiful sight of household goods on the sidewalk where a drunkard's family has been evicted for nonpayment of rent, and regard her as a social parasite.

The managing editor of some of the great papers said to me not long ago: "The greatest victory which the temperance folks have won to date is the creation of a public sentiment to the effect that wealth derived from liquor is not as respectable as 'clean money,' and which has put its possessors on the defensive."

Unless some people who now flatter themselves that they are of the very elect wake up to what is going on they will find that they are without standing in the aristocracy of service and the nobility of unselfishness. And if their intelligence is too dull and their conscience too sluggish to see it, it will be of service to them, as well as to the community, to awaken them with as much of a jar as is necessary.

WILLIAM H. ANDERSON,

Supt. Anti-saloon League of Maryland.

Baltimore, June 16.

FLORIDA'S RECENT VICTORY, FOR WHICH MAY GOD BE PRAISED.

I have just received notice that the good friends of temperance in Florida have succeeded in securing ten different temperance measures. Of the ten, I copy below 1, 3, 8, 10.

1. To prohibit personal solicitation for sale of liquors in dry territory.

3. To prohibit the shipment of liquors from without the State into any dry county or precinct within the State except for personal use.

8. To prohibit the shipment of liquors from wet counties within the State to any dry county or precinct within the State except for personal use.

10. To provide for seizure of all liquors shipped otherwise, or found in dry territory in quantities greater than demanded for personal use.

Perhaps I should add that 37 of the 48 counties of Florida are dry.

Perhaps I might mention that it was my privilege to lend a helping hand in securing the above. The superintendent, in closing his letter, says:

Too great praise can not be given the donors or guarantors of the legislative fund. I constantly thank God for every one of you. Our work would have been impossible without your liberality. And I know that our Father in heaven will abundantly bless you for your liberality and fidelity to his work—specifically the securing of measures moving toward the ultimate extermination of the beverage liquor traffic.

C. W. CROOKE,

Supt. Anti-saloon League of Florida.
Jacksonville, Fla., June 19.

WEST VIRGINIA AND ITS GREAT VICTORY—A KINDLY REBUKE TO A. I. ROOT.

Brother Root:—I send you under separate cover *The Wheeling Advance*, where you will find the latest returns of the wet and dry votes of West Virginia. I felt a little sad when I saw no mention made in GLEANINGS of our great victory in West Virginia. I feel sure, dear old friend, that the good news of our State going dry would fill your soul with gladness. We must give great credit to Billy Sunday and to the good people of Ohio as well as those of adjoining States for our great victory. Our good people are now helping those of Ohio, not only to fight the saloons, but to shut down breweries and distilleries. The prayers of all our good people will do it.

Elm Grove, W. Va., Nov. 27. WM. BITZER.

My good friend, I supposed I had made mention of and publicly thanked God for the overwhelming victory in West Virginia. Your letter came here during my absence or the matter would have been attended to sooner. I am glad to know that Billy Sunday had a part in that grand work. May God send us more Billy Sundays. Since your kind letter was written, some great victories have been brought about, as you are perhaps well aware, not the least among which is the conferring on the women of Illinois the right to vote in that State just as men do. That means an addition of 1,600,000 voters, most of whom can be counted on as being against the saloon.

"OUT OF THE DARKNESS AND INTO THE LIGHT."

Dear Bro. Root:—I'm a subscriber of GLEANINGS, and have been a close reader of *Our Homes*—so much so that your August number has made a remarkable change in me. I've been a user of tobacco for thirty odd years, and I've been able to quit, and have no desire for it at the present time. I have improved in health, and gained fifteen pounds. Not only that, I've been also converted, and I'm now a member of the Baptist Church here. Your writings in the Home Department, and your unselfish plea for righteousness, have had a great deal to do with my spiritual welfare, and I take this means of acknowledging the same, and I hope that you and your good wife may enjoy the best of health, and God grant that the evening time of your life may be thrown out in a long twilight, and you be able to do a great deal more good for your Master yet. This is the prayer of a sinner saved by the grace of God.

Leadwood, Mo., Nov. 11.

FRED WORTH.

May God be praised for what you tell us, my good friend. I trust that, when your eyes rest on this, you will have met no serious discouragement, and that you still are "holding the fort." You have probably

had your share of trials and temptations; and may be sometimes you have felt discouraged; but let me point to you a gem in God's holy word—"Great peace have they that love thy law, and nothing shall offend them." Do not be offended, my brother, no matter what turns up or comes up. Look pleasant; hold on, and the promise will surely be yours. Once more, may God speed you in the new life you have commenced to live. By the way, the above confession reminds me of the following which I extract from the *American Magazine* for October, 1912. The words are spoken by the great reformer Charles B. Towns:

"You can't talk to me about tobacco. The tobacco-user is in the wrong. It undermines his nervous strength. It blunts the edge of his mind. It gives him 'off' days when he doesn't feel up to his work. It always precedes alcoholism and drug addiction. I've never had a drug case nor an alcoholic case (excepting a few women) that didn't have a history of excessive tobacco-smoking. Inhaling tobacco is just as injurious as moderate opium-smoking, and the same treatment is used to destroy the craving. There's a plain fact that has a jolt in it for some of you smokers. I'd like to train about a million men in this country to say, 'It's tobacco!'—like that—'it's tobacco!' whenever they hear a man say he isn't feeling quite fit. A million people saying 'It's tobacco!' every day—that would get us somewhere."

ILLINOIS GIVES WOMAN SUFFRAGE.

We clip the following from the *Cleveland Plain Dealer*:

SPRINGFIELD, June 26.—Gov. Dunne to-day signed the woman suffrage bill passed by the General Assembly. The bill provides that Illinois women of legal age may vote for all statutory offices.

By his signature Gov. Dunne made Illinois the first State east of the Mississippi to give women the right of the ballot. The bill will become law on July 1.

If the men who voted against woman suffrage in Ohio and Michigan do not feel somewhat ashamed of themselves when they see the above, they certainly ought to.

LEVEL CULTURE FOR POTATOES IN FLORIDA.

Friend Root:—GLEANINGS is received, and potato article read. You know receiving this copy of GLEANINGS carried me back 30 years when I was at Sarasota keeping bees and reading GLEANINGS. Those were some of the happiest days of my life, settled in the woods a mile and a half from any house, with my bees and garden. I was then a potato-grower, and read your book on level culture for potatoes, and it was a success. Working dirt to potatoes in this country won't do. They put on small potatoes all up the stalk as far as the dirt covers it.

When I ran a fine-tooth harrow over the ground after potatoes were just through the ground it took lots of faith in A. I. Root not to feel that I had ruined my crop; but two or three days showed to me that you were right.

Bradentown, Fla., June 16. S. C. CORWIN.

I had a fine crop of honey from my back-lot apiary, and feel that much of it is due to A. I. Root.

A HIGH WIND DURING THE MATING HOURS OF THE DAY WILL SOMETIMES PLAY SERIOUS HAVOC WITH QUEEN-REARING OPERATIONS.

ON Sunday and Monday, July 13 and 14, as mentioned elsewhere, a very high wind—almost a hurricane—struck our basswood apiary where there are 450 nuclei for queen-rearing. This wind came up suddenly while the queens were in the air seeking their consorts. The next day, and the day following, showed that the nuclei were queenless. The presumption is that the queens, and possibly the drones too, were carried miles and miles away by the high wind, lost their bearings, and, of course, did not return.

OUT AMONG THE BEES; EDITORIALS INSPIRED BY OUTDOOR WORK.

PERHAPS the discriminating reader may have noticed the larger amount of editorial matter than usual, and the further fact that these editorials smack of actual work in the field. As related elsewhere, our boys have been very much overworked, and hence the editor has been compelled at times to give a helping hand. In order to keep up our correspondence, we have in a few instances transferred the office to the automobile. While the truck is going in one direction the editor and his auto would be going in another with a couple of men. While they were at work among the bees we have been receiving inspiration and delight as we sat in the machine in the shade of a tree listening to the hum of the bees and the song of birds—no telephones, no traveling men, no clerks, no one to interrupt. This morning, July 23, we cleaned up quite a batch of stuff; and if the reader finds any help in our editorial buzzings of late he may lay it to the outdoor air and contact with the bees themselves.

HONEY-CROP CONDITIONS AND PRICES.

THERE is not much new to report this time except to say that the white-clover yield in many localities has been the heaviest ever known; and, strangely enough, there are some places where the clover failed, either because of drouth or an early freeze.

But the yield from the favored spots has been exceptionally heavy if we may judge from the numerous offerings we have received from beekeepers who are anxious to dispose of their crop.

In the mean time it begins to look as if the yield from alfalfa will be below normal in some of the alfalfa regions; but just how much we are not able to say at this writing. The almost entire failure in California, and the lighter yield of alfalfa, will probably prevent a slump in the price of clover extracted. Our Western beekeepers would do well to dispose of their crops in the West where prices will be firmer, rather than unload them in the East and run the danger of smashing the honey market. We see no reason why there should be a great tumble, and hope there will not be. Beekeepers of the East and West should study the markets and ship their crops where they can do the best.

THE SCHOOLS OF DRONES IN THE AIR.

WE have had reports in the past as to how drones would congregate in large numbers—so much so as to seem almost like a swarm. Their very loud noise can be heard at a considerable distance; and when there are thousands and thousands of them in the air, as there are sometimes, they naturally attract virgin queens seeking their mates. An instance of this kind is reported by the manager of our basswood apiary, Mr. Pritchard. As it is such a striking confirmation of what others have reported we asked him to write it up, and here it is:

About 3 o'clock on the afternoon of Monday, July 14, I heard a loud humming over the meadow which borders the south side of the mating-yard at the basswood apiary; and on going out from under the trees I found that a great congregation of drones were flying about, nearly as high as the tree-tops, and that the virgin queens were coming from the mating-boxes in astonishing numbers. When a queen came from under the trees a number of drones (in some instances apparently 20 or more) would circle close about the queen, resembling a small but very active swarm. They would dash high and low for a few seconds until one of the drones would clasp the queen and fall, the rest of the drones following them until they struck the ground. Four such swarms of drones were in sight at one time, and scarcely a moment passed during the few minutes I watched them that one or more was not in sight.

The wind had blown a gale all Saturday and

Sunday, and no drones were flying. Monday forenoon was rainy; but after noon the sun came out bright, and the drones were having their first fly for three days, which probably accounts for the unusual number of queens mating at this time. There are 450 mating nuclei in the yard.

Medina, O., July 15.

M. T. PRITCHARD.

CRACKED-WHEAT MUFFINS AND NEW HONEY.

WE have been eating at our house, for several weeks back, muffins made of cracked wheat which surpass any thing else we have ever tried. We buy the wheat and grind it in a little hand grinder, which can be secured at the large hardware stores or mail-order houses. We do not grind the wheat fine, but adjust the machine so that the flour will be coarse. This cracked wheat is then sifted, the finer portions being used for muffins as aforesaid, and the coarser for a breakfast food which is boiled for four hours over a low flame. When served cold with new honey it is simply delicious. The cracked-wheat muffins served hot with good butter and new honey make a meal—well, just try it for yourself. The muffins have a nice nutty flavor, and the grits covering the wheat itself will clean out the system that may have become clogged up, better than any cathartic that has ever been devised; and it does it in Nature's own way.

We asked Mrs. Root to write out the recipe for the muffins. "Oh!" said she, "any woman knows how to make muffins;" but we doubt if all know how to make something as delicious and fine as we have at our house. Here is the recipe:

Two cups whole-wheat flour; 1 tablespoonful white flour; $\frac{1}{2}$ teaspoonful salt; $\frac{3}{4}$ cup sugar; 2 eggs; 1 cup sour milk or buttermilk; $\frac{3}{4}$ teaspoonful soda; 1 tablespoonful melted butter.

We took out of one of our hives a frame of white-clover honey just built out on medium brood foundation; and, say, you would be surprised that the midrib of the wax is hardly noticeable. We cut this frame up into squares and put it on plates. When served in this way it looks as nice and tastes as fine as the finest comb honey from sections, and at a great deal less cost. Now, then, take some of this honey and put it on a piece of muffin with good butter; and if you do not have a feast fit for a king, we shall be surprised. The wax chews up with the muffin without leaving a particle of "gob."

GREASY WASTE V. DRY COTTON WASTE FOR SMOKER FUEL.

WE use in all our yards greasy waste, and our men all prefer it to any other fuel for smokers; but Mr. Morris, our foul-brood inspector, in one of his trips referred to elsewhere carried with him some dry or clean waste, remarking that he did not like to carry the greasy stuff that would spoil

every thing with which it came in contact. The smoker was loaded with greasy waste to start on; then it was reloaded with dry waste, and all at once we thought the bees were fearfully cross. We could hardly drive them down, and they stung so terribly that once we were driven to cover. We then remembered that Mr. Arthur C. Miller uttered a word of caution against using cotton rags for smoker fuel, saying that it irritated the bees. We did not agree with him, because we had used greasy waste—hundreds of pounds of it—with the greatest of satisfaction. We did not then think that the presence of grease possibly and probably modified the effect. We do not even yet know whether it does or not; but we present the facts as above given; and if anybody else has had a similar experience we should like to hear from him.

We imagine our friend Arthur will be smiling up his sleeves with the grim satisfaction, "I told you so." If there is any one else who can smile with him, we hope he will let us hear from him.

Perhaps it will tone down Mr. Miller's smile when we say that the time when the bees began to get cross was along about five o'clock; but the evening was not cool, nor had the temperature materially changed. Was it the time of day, or was it the cotton waste that made the bees drive us to cover?

It would hardly be proper to print all that Mr. Morris said when some two or three dozen bees, more or less, were hanging by their stings imbedded in his bare arms, such as "You little ——! ——!! ——!!! Ouch!" The crowd of good-natured farmers with their wives had a laugh at his expense.

Later.—We have just had a talk with our apiarist, Mr. Marchant, with regard to dry cotton waste for smoker fuel. "You can tell Mr. Miller," he said, "that he can make that smile a little broader if he likes, because I entirely agree with him. I find corneobs equally objectionable; but greasy waste is all right. My father, A. B. Marchant, of Florida, now uses nothing else. It is the best fuel he ever used."

Still later.—Day before yesterday, July 21, the inspector and ourself went on another tour of inspection. We remarked:

"Say, Morris, are you going to use any more of that dry cotton waste?"

"Why not?"

"You know how the bees stung us."

"Fudge! I have been using that kind of fuel right along."

So saying he proceeded to fill up his smoker with more dry waste. We went over about a dozen colonies; and notwithstanding there was quite a party of visitors

looking on, nobody was stung—much less the inspectors and ourselves. The bees were very quiet.

"We have a story for next GLEANINGS, telling how you were stung when using dry cotton waste."

"Have, eh? Well, it is my opinion that the late hours of the day and the checking of the honey-flow would account for the ugly temper of the bees rather than the fuel in the smokers."

There, dear reader, you have all the pros and cons; and if you have any facts that bear on this question, speak out your mind. Mr. Miller has a complete analysis of the case, and he is at liberty to diagnose it as he likes.

FAIR QUESTIONS: IS IT EVER NECESSARY TO
SHIN UP TREES AFTER SWARMS IN A
MODERN APIARY?

THE following letter is a very natural inquiry. We knew it would come, and here it is:

I noticed last year at swarming time you said in GLEANINGS you were all shinning up trees for swarms and that next year there would be none of that; but this year I notice you are at the very same thing again. What kind of system are you working your bees on that gives such results? Readers would probably like to know, so as to steer clear of it.
Galena, Kan., July 6. J. P. BEUMFIELD.

One apiarist and two helpers are taking care of 500 colonies of bees. These men are able, in connection with the automobile truck, to take care of the whole proposition when conditions are normal. When they are abnormal, they necessarily have to have help at times; and that help this season has had to come from the editorial force, as all other departments were too busy to supply any men; and, besides, we feel that editors ought to rub up against the real proposition from time to time in order to have a proper working knowledge of actual conditions in the yards. But the real question is, "Why is it ever necessary to shin up trees after swarms in the modern apiary?" Dr. Miller once said that he did not have to climb trees for swarms, because he clipped his queens' wings. But we can not practice clipping, because many of our customers do not want the symmetry of their queens marred. Then why not use drone-traps? These put more or less obstruction at the entrances, and interfere with the proper ventilation of the hive. It necessarily follows, then, that when a swarm takes a notion to cluster in a tree somebody will have to do some shinning. But the next question to raise is, "Why allow the swarms to come out in the first place?" Why not cut out all cells, and thus keep swarming down? This will go a long way; but in the height

of queen-rearing operations, furnishing bees in pound packages, sometimes at the rate of 100 lbs. a day, it is impossible to get around to all the colonies if there comes a heavy rush of honey. We had weather conditions for a few days when the bees would fill up their super in five or six days; and, mind you, some of these were ten-frame extracting supers. The honey came with such a rush that it was impossible to get it off in time. Swarming cells got started, and, of course, swarms would come out with supers nearly completed. You may say we ought to have had more men; but when an abnormal and unexpected season comes along it is practically impossible to get all the help needed.

But we are here confronted with another condition. We have one apiary of Carniolans, and these bees will violate every known rule of swarming. For instance, they will continue swarming, even after the honey-flow has stopped. They will swarm without a queen. We have demonstrated that time and again. We had one queenless colony of Carniolans that swarmed, went across the country, and was finally hived by a man about five miles away. The next day he brought them to us, and it took a five-dollar bill to get them. We put them into a hive and gave them a frame of unsealed brood, and they began building cells. It may be said that they lost their queen; but we have had so many cases of Carniolans absconding without queens that we know that this one had none. During the past few days we have had at the rate of five swarms a day from our Carniolan apiary *after the honey-flow had stopped*, and robbing would start up if we were not careful. The other apiaries of Italians ceased all attempts at swarming; but they will not stand overloaded supers or swarming cells.

One of the best beekeepers in Ontario wrote us a few days ago, saying that he was nearly worn out; that he had secured an enormous crop of honey; that the swarms were getting away from him; and, while he would like to get honey, he believed he was about ready to have the flow let up, as he could not do the work. Other practical beekeepers have been hit the same way. Even when clipping is practiced, a swarm will sometimes come out with a virgin, and make for the top of a tree. Somebody has got to do some shinning; and usually it is the overworked apiarist, who can not get help at that season of the year for love or money.

FOUL-BROOD INSPECTION.

FOR the past few days we have been having some experience in going around with

State Foul-brood Inspector Morris. It is not surprising that there should be plenty of bees in and around Medina; and naturally enough the A. I. Root Co. are anxious that there be no disease within reach of our own bees. We have been going out with the inspector several miles in all directions from our home and outyards, and it is surprising to note the number of small beekeepers that we have been able to locate.

Mr. Morris' experience has been about the same as that of most foul-brood inspectors. Occasionally he strikes a beekeeper who looks at the State foul-brood law as an unmitigated nuisance. Such persons feel that the State has no right to interfere with their work or property. When they are approached by the urbane inspector he may give expression to a few cuss words, and talk as if he had a shot-gun right handy. But Mr. Morris' good-natured twinkle and banter are equal to the occasion. He will josh away at the fellow until he gets him to laughing, and then all is smooth sailing. He had an experience of this kind with one man who did not propose to be inspected, but who was, just the same; and Mr. Morris had his good will and friendly co-operation.

Quite different was the reception we received yesterday, July 16, east of Medina. As is his custom, Mr. Morris steps out of the machine, knocks at the door, and asks if the man or woman of the house is present. Then he explains his mission. This is quite an important procedure; and the *manner* of doing it is no less important, said Mr. Morris. It strokes the hair the wrong way to go into a man's yard without asking his permission.

Mr. Morris made a great hit among several beekeepers yesterday. They said they were glad to see him, hoping that he would come their way again. On one occasion the owner called to his wife, who was out in the hay-field helping, because he said she was the beeman. Her greeting, as she apologized for being out in the field, was no less cordial than that of her husband. She had a nice little apiary, and she was up to date in her methods, for she was familiar with the Alexander plan of increase and producing comb honey. She and her husband asked many questions, and at the close of the inspection work they both expressed their pleasure at having been honored by a visit from a State official. They were delighted, also, to learn that their bees were nice stock, and that they were able to present a clean bill of health.

They readily gave us the names of other beekeepers, and jumped into the machine and helped us to inspect. "My!" said Mr.

Morris, after finishing up his afternoon's work, "that was a great snap. If a fellow could always strike an enthusiastic beekeeper and get him or her to go around and introduce us to the rest of them, every thing would be lovely."

Mr. Morris left a pleasant impression. He is a great story-teller and a joker; and while he is telling a story he throws in practical suggestions that make a beekeeper feel that the State, so far from interfering with his property and business, is giving him a real help.

Chief Inspector Shaw has a corps of men that are doing splendid work, notwithstanding the powers that be have cut down their appropriation to an amount much smaller than last year. Prof. Shaw, however, is economizing in every way possible; and if our men who are higher up in authority could only know the good these little appropriations are doing to the farmers and beekeepers at large, they would spend their money more judiciously. Well, to return:

When Mr. Morris and ourself started out on the afternoon of the 15th we had to feel our way. We did not know how many beekeepers there were, nor where they were located. Once we stopped near a lot of rank sweet clover. It was fairly covered with bees. We remarked that there must be a lot of bees somewhere near. Apparently they came from one of our outyards two miles and a half away, but yet that did not seem probable. We then began lining up, which was somewhat difficult, owing to the position of the sun. We were of the opinion that there must be a lot of bees near at hand. A drive of a quarter of a mile down the road soon brought us in contact with some thirty odd colonies within about an eighth of a mile of each other. This particular location has never had any bee disease, and apparently never will have.

HOW THE ROAD SUPERVISORS CUT DOWN
SWEET CLOVER, AND LET THE REAL
WEEDS GROW.

Every now and then we could see where the road supervisors had cut down sweet clover, a genuine forage plant, and had left the noxious weeds of the very worst kind along the ditches and on the banks. Sweet clover follows the road, and can be very easily reached by a mowing-machine, so the road supervisor reaches out as far as he can, and, of, course, destroys the sweet clover and only that.

Professor Shaw was very anxious to get an amendment to our law, eliminating sweet clover from the list of noxious weeds; but our Ohio legislature was jammed full of other bills, and many needed laws were sidetracked.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

CLOVER-YIELD began here ahead of any thing ever known before. What the drouth will do with it remains to be seen.

B. M. CARAWAY reports that in Texas bees get nectar and pollen from beans. Texas may yet rival California with its big bean-fields.

MR. EDITOR, when beginners read, p. 433, about your "shinning up trees" after swarms, some of them will be likely to ask, "Why don't you clip your queens?"

OTTO DENGK reports, *Leipz. Bztg.*, 17, that colonies which had not quite filled out their hives with comb the previous year were 8 to 14 days earlier to swarm than those which had no comb to build before swarming; and this was so year after year.

ILLINOIS is a good State to live in, and I'm more proud of it than ever before. The legislature has passed a bill, and the governor has signed it, which gives women the right to vote for presidents, mayors, etc., including the right to vote for or against saloons. You may be sure the liquor men didn't work hard for the passage of the bill. Sorry for your Ohio women. But it's only a question of time.

RIGHT you are, Mr. Editor, p. 437, in thinking "that more and more beekeepers are beginning to accept the deep space under the frames as better than a shallow space." It's a hard job for me to use properly the English language. What I was trying to say was that more and more beekeepers were not satisfied with a space as small as half an inch, or even an inch, between floor and bottom-bars.

I'VE always had just a little doubt as to the statement that bees are of more value as fertilizers than as honey-gatherers; but that cranberry business, p. 479, may yet remove all doubts. I hope we may soon have definite figures as to the actual gain in dollars and cents made by the bees. It may make some of us old fogies open our eyes. Then may be we could also get figures of the same kind for the apple and other fruit crops.

DANGEROUS, perhaps, to but in in that Byer-Chadwick squabble, p. 441, but I think it quite possible both men may be right, and that "locality" may again be a factor. In Canada, the cold prevents the rapid building-up of a colony in an eight-frame hive, as compared with the stronger colonies in ten-frame hives, while in the warmer California clime the colony in the small hive

builds up rapidly, and can sooner be squeezed into supers than if in a larger hive.

A CALIFORNIAN wants my latest "think" about European foul brood. I *think* that, in its treatment, ten days—possibly a week—without a laying queen, is long enough; that under any kind of treatment the disease is likely to crop out again. By prompt treatment you can get good crops in spite of disease; and yet it takes very little of it to lower materially the yield of a colony. My hybrids seem as resistant as the Italians, yet further experience may show the Italians ahead. In general I think Italians are better at cleaning up than hybrids. At any rate, if I had average hybrids I'd hustle to get in the best Italian blood I could find.

EXASPERATING. I don't know any milder word for the feeling one so often has when honey is mentioned with no hint whether comb or extracted is meant. An instance occurs in GLEANINGS, p. 478. "Our foreman has set his stake at 100 lbs. per colony, spring count." I'd like to beat that if I can, but how do I know where to set my stake without knowing whether that 100 means comb or extracted? Which is it, Mr. Editor? Another case is foul brood. With no qualifying word, how can one tell which of two distinct diseases is meant—American foul brood or European foul brood? [In connection with our honey-yields we have spoken of power extractors, honey-pumps, capping-melters, etc. We have said nothing about the production of comb honey in sections, so we did not think it necessary to specify extracted when we were talking only about that. We grant you, however, that it might be well to specify each time what is meant, because it is much easier to produce 100 lbs. of extracted honey than the same amount of comb. As a matter of fact, 90 per cent of our honey will be extracted, and 10 per cent will be in shallow extracting-frames to be cut up into small squares. These will be put into cartons for Pullman-car service. In running for the production of bees and queens it is not practicable to produce comb honey in sections. Our crop is, therefore, bees and queens, extracted honey, and a very little cut comb honey.]

When we speak of foul brood we very often use it in a general sense, meaning either one of the contagious brood diseases. As we have no European foul brood in this locality, and never did have, the term "foul brood" has reference to the common or old-fashioned kind—namely, American foul brood.—ED.]

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

TEN-FRAME COLONIES READY FOR THE SUPERS FIRST.

P. C. Chadwick, page 441, reads more out of that item of mine taken from the *American Bee Journal* than I intended. He says that, when I say my bees always enter the supers quicker from the large hives than they do from the eight-frame L., I upset the theory of an eight-frame hive for comb honey. By "supers" of course I meant extracting-supers, as I produce extracted honey almost exclusively. Entering comb-honey supers is a different matter altogether, as we all know that, for producing comb-honey, the bees have to be crowded to a certain extent. I have no ax to grind in the matter of sizes of hives; but it has certainly been my experience always, that the larger hives are ready for the extracting-supers nearly always before the few eight-frame hives that I have.

* * *

I am strongly in favor of having an abundance of old stores in the hive during a long period of cold weather like that which we experienced this year. Two of my apiaries were rather short this spring although no colonies actually starved. The other apiaries had an abundance. All were equally strong in bees at the start, but what a difference later! Those that were heavy, stored honey in the supers—many did that in willow bloom. The ones a bit short merely held their own through all the cold weather, and many had to be fed to keep them going; while as to measuring up with the other colonies referred to, they are not in the same class. Yes, the longer I keep bees the more I am in favor of "millions at our house," as friend Doolittle expresses it, and spring feeding is more of a nightmare to me than ever. Good job that this is a free country, as the man who likes to have the colonies light in the spring and then tinker with them for months is quite free to do so; while on the other hand, careless free-and-easy chaps like the writer can "stuff them" in the fall and leave the bees alone until willow and fruit bloom.

* * *

SEASON PROSPECTS.

The writer of these notes has been going at a terrific pace for the past three weeks; and at this date, July 7, his fingers are gummed with propolis so that it is hard work to run the typewriter. Perhaps this is an exaggeration; but at any rate my fingers are sore from handling frames; and the

hum of the bees is so persistent in my ears that writing is almost out of the question. We have had a fine crop of honey here in York Co., and the quality, I think, is the best I ever handled. The yield at the north yard has been light, owing to late heavy frosts that cut the clover badly, and then the damage was increased by severe drouth which followed the cold. Reports received as yet are meager; but those from the east say failure, while from western and central Ontario reports are mostly good.

Many reports from the east of Ontario and some parts of the north as well—our own Lovering yard unfortunately being among the number—state that the caterpillars have stripped all the foliage from the basswoods so that there will be no honey from that source in those sections. This pest seems to come periodically, and it is to be hoped that next season will not see a repetition of the plague or there will be danger of the trees being killed outright.

In this locality buckwheat promises well, and recent showers are bringing it along nicely.

* * *

RECORD-KEEPING TAKES TOO MUCH TIME.

Right you are, friend Foster, in what you say regarding book-record systems for the beekeeper who runs hundreds of colonies. From personal observation I am led to believe that not one out of ten who have 200 or more colonies continue very long to use any style of record-keeping that is at all complicated. Yet for all that it is surprising how an extensive beekeeper may "know" so many of his colonies in so far as their record goes from year to year, even when nothing but a hive number or some other marking is the guide to remember them by. Especially is this true where outdoor wintering is practiced and the hives are not changed around very much.

A short time ago, while at one of my outyards I was thinking over this matter, and, by way of test, I made a critical survey of the apiary of about 100 colonies, and in nearly every case I could mentally tell myself just about how every colony had done for the past three years, even when the hives looked nearly all alike. In the majority of cases I am afraid other fellows do much the same, and, all things considered, I do not think it would pay *me* to try to keep any systematic record; indeed, it would be only a "try" for a short time any way, to be discontinued some time when exceptionally busy.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

My bees in town are securing sufficient honey from the pepper trees to keep them breeding nicely. I have divided most of my home yard of 15 colonies. If the bees keep up their present rate for a few weeks some of them will be divided again. Conditions are not so favorable out in the foot hills, where it is very dry and little is doing.

* * *

There were but two days between May 15 and June 15 when there was not fog for a portion of the day. On some days it would last but a few hours, while on others it continued well into the day. This condition ended June 25, with a very unusual rainfall for the time of year, amounting to .40 of an inch in Redlands, which was about an average for the storm. Now, however, we are getting next to the warm side of the sun, the temperature slipping almost daily above the century mark in the interior foothill region, and no trace of the little rain is left. It is not so warm near the coast. A press dispatch from Imperial Valley reports the temperature as having reached 124 on July 7. However, this excessive heat in such a dry climate is not so hard to bear as 100 degrees would be in the more moist air of the eastern States.

* * *

ITALIANIZING.

The question of requeening has agitated my mind more during the past season than at any other time during late years—not that I have been in doubt as to the advisability of requeening with good Italian stock, since black brood is creeping this way from the west, but rather how best to get the pure stock the most quickly and most surely. I have purchased many queens, a few at a time, in my beekeeping life, and for the most part I believe my money has been spent for naught—not that I did not receive what I paid for, but the introducing of a few queens now and then to an apiary of mixed stock seems to me from past experience to be a waste of both time and money. Eight years ago I purchased about 75 queens of different races, which were introduced, but no further effort was made to stock up from any one strain tried, for these queens were purchased as much for an experiment as any thing. But the experiment proved a failure, for at the end of the second season my stock was worse mixed than ever. I have tried about every race of bees known to this country, with the exception of the Caucasians—not one or two of a kind, but enough to make a fair

test, and have come to the conclusion that the Italians are the best all-around race. I am a lover of the goldens, and to that end I am requeening with the light-colored Italians.

* * *

SMALLER PACKAGE WANTED FOR EXTRACTED HONEY.

There is a constantly increasing demand for a smaller package of extracted honey put up by the beekeepers, and under a seal or guarantee of the producers. This is not at all strange in this day and age of the world, when people are in such a rush to keep up with the rest of the world in the mad rush of life. Go into any grocery and observe how almost all goods are handled now days. You call for oatmeal. It is so much a package. If you want vinegar you do not send the little brown jug to the store as of old, but are handed a bottle from the shelf, neatly labeled, and ready for the consumer. The same with nearly every thing in the grocery line. If one goes to a store to sell honey he is often asked how it is put up. He informs the prospective customer that it is in five-gallon pails, two to a case. He is told that it is too bulky to handle in that way; that the trouble and time necessary to put it up in smaller quantities for the consumer make it out of the question, and that, any way, they are getting their honey from J. Jones & Co., put up in smaller amounts just to suit the trade. Well, Jones & Co. get their honey, in all probability, from some dealer who has purchased it from the producer. The dealer is paid a good profit over what he has paid the producer; and the packers, Jones & Co., get a substantial reward for their trouble in getting it ready for the retail trade. This packing should be done by the beekeepers, either individually or co-operatively, and thus save two or three margins paid to middlemen. If fifty or one hundred of the leading producers of this State would agree to ship their honey to a central point, to be graded and put up in packages to suit the retail trade, this object would be accomplished, and a neat profit in addition could be turned into the pockets of the producers. But it is doubtful whether so many producers could be persuaded to enter into a mutual agreement of this kind, for most of them like to do a little business on their own hook, and are jealous for fear the other fellow will get a penny or two more out of the deal than they. There will always be a demand for the packer's product, but we could increase our sales very much by some effort on our own part.

Beekkeeping Among the Rockies

WESLEY FOSTER, Boulder, Col.

CHICO OR GREASEWOOD.

I am glad to have the correction of Mr. J. A. Green regarding my description of chico instead of greasewood. I took the word of the beemen with whom I talked about it, and I should like to hear definitely from some authority. I have just received a letter from a western-slope beekeeper who says the chico is in bloom (June 1), and is furnishing pollen in excessive quantities. Is it chico or greasewood?

* * *

HONEY PROSPECTS.

Feeding through June was necessary in the lower Platte Valley. Some of the districts were so burned by the drouth that it was difficult to keep the bees alive without nearly bankrupting the beekeepers. Sweet clover dried up in the sandy river bottom, and the first alfalfa had little nectar in the bloom.

Prospects do not compare with a year ago in Northern Colorado. We need rain badly; and at this writing, July 2, none of my colonies are working in the supers. We shall have no honey off before July 4, as we generally do. Sweet clover is coming in bloom where it is not already burned by the drouth. We are two inches short of our normal rainfall so far this year. If we could collect the two inches of rainfall before July 10 it would be worth much to the beemen.

In the Arkansas Valley, conditions are better. While rain would be very welcome, the alfalfa and sweet clover are yielding well, and some few cases of comb honey were taken off before July 1. Swarming was more general in the upper Arkansas Valley than lower down.

Grasshoppers are reported thick in the vicinity of Holly, but they are not getting into the fields very far.

Bees were working well on the alfalfa first crop in places heard from in Western Colorado, so conditions are probably fairly well up to normal.

In Southwestern Colorado the season is generally slower in beginning, probably on account of the June freeze that visits that section almost every year. The colonies, however, are in fair shape, and prospects seem to be good for a July and August flow, and perhaps one will materialize in September.

* * *

CREDIT FOR THE BEEKEEPER.

Throughout the great West the proportion of specialists to amateurs and small

beekeepers is large. A considerable proportion of the smaller beekeepers plan upon taking up beekeeping as a specialty.

In buying bees, cash sales are the rule, or at least a large initial payment is required. The reason for this is the rapidity with which an apiary may decrease in value and numbers. The value of bees depends much upon the ability and skill of the beekeeper; and, added to this, an apiary is much subject to conditions of season and climate.

Many apiaries are bought with a down payment of one-third to one-half, and the remainder at the end of one year, or possibly two. When such a large amount of the principal is required the first year, the bees have to do exceptionally well the first season in order to enable the beekeeper to hold his own and to meet the expense for supplies, location rent, horse and wagon, or auto, living expenses for several months till honey can be sold, in addition to the interest on principal and the principal, which is soon due. Interest rates are from 8 to 15 per cent in the West, and in many cases there is a two-per-cent commission besides. I am fairly conversant with beekeepers', farmers', and gardeners' conditions; and the bane of them all is insufficient capital and excessive interest rates on short-time loans. If the average beekeeper could borrow according to his credit at 4 to 5 per cent, with ten to twenty years to pay, instead of at 10 to 12 per cent with one or two years' time the prosperity of the industry would be wonderfully increased. There are hundreds of apiaries that have dwindled through winter losses that could be built up with a supply of low-priced money so that bees could be bought and shipped in to fill these hives.

Why the Bees Balled their Queens

Can you tell me where my trouble lies with my bees? I have two small out-apiaries. I clip the queens' wings, and cut out cells to prevent swarming. Now, I found in going through them at different times that they had the queen balled, and, later on, the colony would be queenless. They are the Italians.

Caldwell, Ida., June 21.

CECIL LEPPIN.

[We hardly know what should cause your bees to ball the queen unless the disturbance in opening the hive in cutting out the cells should cause them to become dissatisfied. Sometimes when the normal conditions of a colony are disturbed the bees will ball their queen, apparently thinking she is to blame for it. It is not an uncommon occurrence, when a swarm tries to leave with a clipped queen, for the bees to ball and kill her on the second or third fruitless attempt. Possibly this is the real cause of your trouble.—E.]

Conversations with Doolittle

At Borodino, New York.

SECTIONS, WHEN PUT ON, ETC.

"How many sections should be put on a colony? How may one know the right time to put them on so that he may secure the best results? I do not have the flow of nectar from clover and basswood that some do; but from buckwheat and fall flowers the yield is often fine."

"After many experiments I have come to the conclusion that sixty pounds capacity is about right for a good strong colony, say one having from 45,000 to 50,000 bees when worked for section honey, and 100 pounds when worked for extracted honey, exclusive of the brood-frames or the hive proper. In putting on sections it is always best, where it can possibly be done, to have a part of those first put on filled with comb left over from the previous season. This starts the bees at once to storing above, at the commencement of the honey harvest, whether from clover, basswood, buckwheat, or fall flowers. Don't wait till your bees swarm before putting on the sections, as some do, fearing that the sections will retard the swarming, for bees often refuse to swarm, and hang idle on the hive all summer, where the season is such that they are anxious for storing a copious flow at the start. Always keep an eye to business, never forgetting that a thing done at the right time brings success.

"In order to take advantage of the very first of any nectar flow the sections should be all in readiness in the supers before that harvest is likely to arrive. The practical, successful apiarist does all of this preparatory work during the winter months, although he does not yet know how his bees will winter, or what the harvest will be. Having every thing in readiness before the active season opens will pay much the best.

"I have to confess that, to know *just* when to put the supers on the hives is often difficult, especially where there is an early flow; for if put on too early, brood-rearing is often materially retarded; and if put on when there is no honey coming in, although there may be plenty of bees so that the brood does not suffer, these bees, not having any thing else to do, will often go into the sections. Apparently bent on mischief, they will then amuse themselves in gnawing down the foundation starters, or in daubing every thing with propolis. This causes a delay in entering the sections for work, when the harvest does arrive.

"The old rule of half a century ago was to put the sections on when the first blossoms from white clover appeared; and for

those days of box hives perhaps this was as good advice as any; but for those who handle their bees and know their condition in each hive, none will be willing to adopt such a rule. Let us see how it would work: A few years ago a prominent apiarist wrote me about the middle of June that his bees were not in the shape that he wished them, saying, 'About a third of them will be ready to take advantage of the clover; a third more, with the first third, will be ready for the basswood, while the remaining third will not be strong enough to work to advantage on any thing but buckwheat and fall flowers.' Now, it will be seen easily what a waste it would have been to put the sections on all those bees according to the advice given by our grandfathers. But we will suppose that the bees are strong enough to enter the sections, and clover, basswood, and buckwheat, or whatever gives the surplus honey in our locality, is commencing to bloom—shall we put them on? No, not until nectar is coming in. One year, in which my average yield from the whole apiary was over one hundred pounds of section honey from each old colony in the spring, the sections were not put on until from July 12 to 15. Previous to that time the bees were living only from hand to mouth, being so short of honey that a week of rainy weather would have starved them if I had not come to the rescue by feeding.

"When every thing is in readiness, 100 hives can be supplied with surplus arrangements so quickly that no time need be lost after the flowers begin to yield nectar. In order to ascertain whether nectar is yielding, go along the entrances of the strongest colonies each day, and, by the actions of the bees, tell whether they are gathering honey or not. If you are not sure that you can tell in this way, it is a good plan to wait before putting on the sections until you find little bits of comb started, or until nectar glistens in the cells lengthened along the top-bars of the brood-frames. When you see this, and the colonies are strong enough to enter the sections, don't delay putting the supers on such hives a single day; for if you do you will be losing honey, for the bees may begin to crowd the queen, and thus be slow in working in the sections all the rest of the season. The first nectar, as nearly as possible, should go in the supers; and if we can so arrange it that the supers are put on at just the right time, nine colonies out of ten will take advantage of them if the first are supplied with bait sections of comb as at the outset."

General Correspondence

THE POSSIBILITIES OF BEEKEEPING AS A SIDE LINE

BY N. FRED GARDINER

[The following article is the substance of a paper read at the last convention of the Oklahoma Beekeepers' Association by Mr. Gardiner. This explains the quotations made from the various books, etc. As it deals with the possibilities of bees as a side line or recreation, we are glad to reproduce it here.—Ed.]

It has been stated by the publishers of one of our leading bee-journals that they believe that fully 90 per cent of their readers are what could be termed "back-lotters"—that is, they keep bees on a back lot or in their dooryards as a side line while they follow some other business or profession. This is likely true of beekeeping in general.

Since the greatest number of bees are kept as a side line, the more astonishing, then, are the yields of honey and wax and the value of the same. I have found it very difficult to obtain any figures on the product; in fact, I could get none whatever from the 1910 census. The 1900 census gives the honey production in the United States as 61,196,160 pounds. Our authorities think that these figures are exceeded by the comb honey alone produced, and likely these figures should have been doubled at least. As an illustration of how unreliable these census figures must be, it will be necessary only to state that it has been the practice of the census bureau to list only the bees on farms or tracts as large as four acres. Therefore we sideliners haven't done much to raise the figures in the census reports. Why, don't you know I raised 1500 pounds this season myself? Then if we double the figures of the 1900 census report we have over 61,000 tons, which is not likely too large.

One of the most astonishing features of this is, that this great volume of sweetness was not piled up by a steam-shovel, but by a small insect, a small part of a drop at a time under the direction of *us sideliners*—90 per cent of it any way.

But we must not get a wrong impression of what this side line means. We must not think that, because of the term, we are to secure a few hives of bees and set them over against the line fence or in some out-of-the-way corner and visit them only to replenish our depleted larder or secure figures for the census enumerator.

I believe I can say without contradiction that there are but two conditions under which beekeeping can be counted a success. One is where it is followed by a specialist for the "almighty dollar," and the other by the side-liner from pure love of the work.

However, it is not infrequent that the side-liner allows the object of his affection to grow so that he finds that he has become a specialist.

The words of Dr. Bohrer before the 1909 convention of the National Beekeepers' Association I consider good wisdom for those contemplating becoming a sideler or possibly a specialist. Dr. B. says in part, "I have made it a custom for several years, especially since foul brood has come into the country, to discourage all persons who know nothing about the management of honeybees. When they talk to me about buying them I tell them that, unless they study standard works on the habits and management of the honeybee, and read the bee-journals, they can buy decidedly more honey than they will ever get out of bees by owning them."

For my part I have frequently been instrumental in securing for interested friends bees in modern hives, or have assisted in transferring from boxes and logs and gums into modern hives, and then have watched their interest lag and have seen the bees left to utter neglect.

On the other hand, here are some inspiring words from Mrs. Comstock, in the A B C and X Y Z of Bee Culture, on beekeeping for women. I quote from this chapter the following:

"I should put first of all, and as embracing all other reasons, that beekeeping may be an interesting avocation which may be carried on coincidentally with other employments; it is an interesting study in natural history; it cultivates calmness in spirit; self-control and patience; it is 'a heap' of fun; incidentally it may supply the home table with a real luxury; and it may add a very considerable amount to the woman's spending money. It may also be carried on as a regular business and be made to support a family.

"But it is as an avocation that I am especially interested in the apiary. Any woman who keeps house needs an avocation which shall take her mind and attention completely off her household cares at times.

"Beekeeping is one of the best of these life-saving, nerve-healing avocations; it takes the mind from household cares as completely as would a trip to Europe, for one can not work with bees and think of any thing else. Some of the attributes which make beekeeping an interesting avocation I will mention: First of all, the bees are such wonderful little creatures, and so far beyond our comprehension, that they have for us always the fascination of an

unsolved problem. I never pass our hives without mentally asking, 'Well, you dear little rascals, what will you do next?' The bees are of particular interest to women for several reasons. If she likes good house-keeping, then the bee is a model; if she likes a woman of business, again is the bee a shining light; if she is interested in the care of the young, then is the bee nurse an example of perfection; if she believes in the political rights of woman, she will find the highest feminine political wisdom in the constitution of the bee commune. In fact, it is only as a wife that the bee is a little too casual to pose as an ideal, although as a widow she is certainly remarkable and perhaps even notorious. Another phase which makes beekeeping a pleasing avocation for women is that much of the work is interesting and attractive. I never sit down to the job of folding sections and putting in starters without experiencing joy at the prettiness of the work. And if there is any higher artistic happiness than comes from cleaning up a section holding a pound of well-capped amber honey and putting the same in a dainty carton for market, then I have never experienced it.

"As a means of cultivating calmness, patience, and self-control, the bee is a well-recognized factor. Bees can be, and often are, profoundly exasperating, and yet how worse than futile it is to evince that exasperation by word or movement! No creature reacts quicker against irritation than does the bee. She can not be kicked nor spanked; and if we smoke her too much, we ourselves are the loser. There is only one way to manage exasperation with bees, and that is to control it, and this makes the apiary a means of grace."

While these words are a message of a woman to women, they are words of wisdom to any who contemplate getting bees.

One of the most interesting things in connection with the bee is its adaptability to so many different climatic conditions. Apparently being able to adapt itself to any locality that will furnish the necessary nectar-producing plants, C. P. Gillette, of the Colorado Agricultural College, in a lantern lecture before the Colorado Beekeepers' Association, said in part:

"The honeybee is, with the possible exception of the silkworm, the most important commercial insect. Although the bee is handled and cared for throughout its life by man, it can hardly be considered a domesticated animal. A colony of bees in the apiary differs from a colony of wild bees in a bee-tree or a ledge of rocks only because of the difference in the home they dwell in. The insect intelligence is not capable of

being taught as one might teach a dog or a horse.

"Bees do wonderful things to provide for their home needs and the care of the young; but they do all from instinct, and not from education received from others after they are grown.

"There are a great many fossils of insects found in rocks of the earth's crust that must have been formed at a time long before man inhabited the earth. It is altogether probable that our honeybee was present upon the earth gathering nectar and pollen, cross-fertilizing plants, and caring for its home, before the earth was in a condition to be inhabited by human beings. We are also interested in the honeybee because it stands at the head of its class, thus rather ranking in the insect world with man in the realm of higher animal life."

While the bee is of great commercial importance to man as a gatherer of one of the choicest sweets that we have upon our tables, it probably is of even greater benefit in the cross-fertilization of the flowers of our agricultural fruits and plants in so causing larger crops.

Mr. John Fields, editor of the *Oklahoma Farm Journal*, and able exponent of alfalfa and Bermuda grass, says, "We feel that an extension of the bee industry would help extend the acreage of alfalfa, and that everybody would be all the happier as a result."

Well, I am not sure whether I am in the big field of beekeeping as a side line or not, but will call your attention to the words of Mr. Doolittle as to the necessary requisites for a successful beekeeper.

"Like all other branches of rural economy it demands care and experience; and those who are conscious of a strong disposition to procrastinate and neglect will do well to let bees alone unless they hope by their systematic industry to reform evil habits which are well nigh incurable. If you are to succeed you must be so absorbed in it that you will think bees, talk bees, dream bees, and never tire of their study. You must be one who anticipates their every want, and one who will do the right thing at the right time."

Root's A B C of Bee Culture has this to say about bees as a side line:

"The keeping of bees is generally more successfully carried on in connection with some other business. Many a professional man desires some sort of light recreation, and a few bees will afford him just the diversion he needs. Farmers, fruit-growers, or horticulturists, can keep from 50 to 100 colonies without greatly interfering with

other work; and nearly every one can keep a few colonies in his back yard. Ten or twenty colonies will yield almost a certain return—a much larger revenue, per colony, than ten times that number.”

With the knowledge that from ten to twenty colonies can usually be handled successfully, and at a good profit, the beginner will naturally desire to try his hand at it. How shall he make his start? Whenever possible, buy bees in your own vicinity. Regarding the price, a strong colony of Italian bees, with tested queen, in a new Dovetailed hive, or any modern hive, in fact, might be worth \$10.00. This ordinarily would be considered the outside price. Ordinarily, bees that are hybrids or blacks, in movable-frame hives, second-hand, sell from \$3.00 to \$5.00 per stock, including the hive. If there are no modern beekeepers in the vicinity, one may have to purchase a box hive or two with the combs all built solid into the hive. The price of these, if they are blacks and hybrids, generally is from \$1.00 to \$3.00. So far as my knowledge goes, there are not many bees in Oklahoma of the kind and condition of these last mentioned, and I hope there will never be many.

The same author just quoted has the following to say under profits of bees: “On the average, perhaps, in the Northern States, in what is known as the rain-belt, one might expect to get anywhere from 25 to 50 lbs. of comb honey, and perhaps 25 to 50 per cent more of extracted. There will be some seasons when he might secure as much as 100 lbs. on an average, and occasionally seasons when there would be neither comb nor extracted, and the bees would require to be fed. Taking one year with another, a small beekeeper ought to average about 35 lbs. of comb honey, on a conservative estimate, providing he has reasonable skill and love for the business.”

The author then makes an estimate of the expenses, and places the net profit at four to four and a half dollars per colony. Continuing he says:

“The question of whether one should keep few or many bees will depend upon many conditions; the principal one will be the ability of the man. Many a person can handle a few chickens, and get good results; but when he runs the number into the hundreds he meets with failure and disappointment. Some of our friends have done remarkably well with a few colonies; but **when they attempted to double or treble the number they entered into a business proposition that proved rather too much for them.**

“A good many, on account of a lack of experience or of business ability, not under-

standing their own limitations and those of their localities, will plunge into beekeeping too deeply and meet with disaster. There are undoubtedly some people who can keep more bees by scattering them in outyards, and if they have the requisite training and business ability they can make more money. But where we find one person who can manage 500 colonies or more successfully, there will be dozens of others who can not go beyond the 200 or 300 mark. The same rule applies to any business.”

As for myself, I began beekeeping when a mere boy, and have kept them as a side line, while a farmer boy, schoolteacher, and railway postal clerk. Their principal attraction for me seems to have been occasioned by my becoming inoculated with the germ of bee fever, which must have been quite early, for my parents tell me that when a mere infant I was found with a stick poking into a hive, undoubtedly making foul-brood inspection. As with many others, my liking for the frisky little insect is such that I would persist in keeping them about me if their presence produced but little or no honey for home use and the market. It may be pure luck, but there has never been a season when I had bees that I did not secure enough surplus to pay interest on the investment.

Although I made an early beginning with bee investigation, there were none for my study when I became old enough to understand them. When I became old enough to read understandingly I was fortunate in securing through a friend some of the most up-to-date books and periodicals on the honeybee. Although I could not then remember ever having seen a bee, the articles so excited my interest that I was not long in securing my first colony, since when I have worked out my own course with the aid of the ample literature that is now available, and without the aid of any one who knew more of the little creatures than I did to give me personal instruction.

My average in 1909 was 91 pounds, spring count, and 95 pounds in 1910, and doubled my stock in each case. This past season the flow ended July 23. This seems to be a good yield for the season; but one of my neighbors, a boy of 16, reports a yield of something like 150 pounds per colony.

The same season that I purchased my first colony I found a bee-tree of black bees. This at once put me into active practice in cutting the tree, transferring the comb, and changing the black queen for an Italian. My stock since then has steadily increased; but I have never owned more than about 30 colonies at a time. While employed as a

schoolteacher my bees did not secure the attention they required; for while the honey was very acceptable on the table my folks did not have the same enthusiasm that I did in caring for the bees, and I finally disposed of them for that reason.

Soon after establishing a home of my own I remembered my former pets and invested anew. As my better half takes almost as much pleasure as I have in their care, my bees now receive pretty good attention.

Geary, Okla.

THE RESULT OF EIGHT SUMMERS' EXPERIENCE

BY ROSCOE F. WINSON

In the spring of 1905 I purchased a colony of bees of a neighbor, and thus commenced a business the managing and working of which I like better than any other rural occupation now open to young men. My first summer's experience came when I was not quite fourteen. Ever since I can remember honey has had a great attraction for me, so it was but natural that my taste should be satisfied.

About the first of May my first colony was moved home and placed on a stand in the yard. When the bees became strong enough, sections were placed on the hive and watch was kept for swarms. During that summer the total crop of honey was about 25 pounds. The bees were increased through two swarms; but the parent colony died of queenlessness, leaving me two to winter.

During the season of 1906 the two colonies that wintered increased to four or five. During those years school duties occupied most of my time, so beekeeping was simply a side line.

The purchase of a three-frame nucleus of Italian bees and some new Danzenbaker hives completed the great deals for the summer of 1908. The cost of these Italians, including the express charges on them, was about five dollars. At that time I expected the "Goldens" to be wonderful; but they were far from it, because it was well into the next summer's clover flow before they paid their expenses. The purchase of good queens (which I made later) would have been the wisest course.

There was not very much done to stir any beginner with enthusiasm except chasing swarms to the woods in the period of the honey-flows of 1909, '10, and '11. I bought a few queens in these years for the weaker colonies, but no wholesale requeening was attempted. Several box hives were bought

to experiment on, but in most cases they proved rather poor material.

In 1909 a man who wished to go out of the business sold me his entire stock of eight-frame hives with three colonies of bees. Although the bees paid for themselves the first season, the eight-frame hives have been a bother ever since, and I still have them in storage, waiting to be converted into ten-frame. My books showed the following summer something like 17 colonies and a total crop of about 636 sections.

I wish especially to relate my experience for the summer of 1912 and the result of fighting European foul brood. I think that when the honey-flow commenced in the latter part of May I had about 38 colonies of bees. Eleven were in box hives, 15 in Danzenbaker, and the remainder in eight and ten frame standard hives. Let me add here the fact that the box hives in the yard were purchased the fall before, entirely for the purpose of speculation. Last September I purchased fifty empty hives for the expected increase, and planned to receive enough swarms from these colonies to fill all hives. Early in the spring the bees appeared quite healthy, and I had great hopes of a good and prosperous year. As time went along and fruit bloom came and neared its close I noticed that some of the box hives which had been strong in the spring had not increased in strength, but were, on the contrary, decreasing. I might mention here an example of good stock, and of what it means to have Italian blood in the yard. One hive in the yard was headed by an Italian queen from a firm in Indiana, and had always proved fairly good. This spring, when natural pollen began to come in quite freely, this particular colony was rather weak, while I had at least two or three colonies in box hives which were at least double in strength. Now for the point: As the season advanced, the Italians gained steadily on the blacks in the box hives. The box hives seemed to be losing bees every day. There seemed to be something the matter, for bees in their natural state never acted like that before. The only way to find out was to get at some of the comb in the boxes. After the bees were drummed out and placed on a set of combs I examined the brood-combs. They looked decidedly queer. The next day I mailed a small piece of comb to the Department of Agriculture at Washington, and in a few days received notice that European foul brood was the disease present. At once all of the hives were inspected, and every colony was found to be diseased except the above-mentioned colony of Italians and a colony of Banat-Italians. Five out of seven were diseased in an out-

yard at the other end of town, so I had only four colonies to depend on for a crop. This happened about the first of June.

Before many days passed I had a visit from Mr. Chas. Stewart, one of the New York State bee inspectors. He looked at the worst ones and advised me to clean up by the Alexander method on the frame hives and the shaking plan for the box hives. From thence I waged war on foul brood. It might do to mention here that the Italian colony was working in 56 sections when the inspector arrived. The foundation was rather late in arriving from the factory, so it was well into the clover flow before any actual move was taken to drum out the bees from the box hives. As soon as the foundation arrived, business commenced. Three box hives that were grouped close together were run out by the forcing-box method, and dumped in front of a ten-frame hive filled with full sheets of foundation, and provided with one super of 28 boxes. All box hives in the yard were treated in this fashion, and the hives with what brood and bees were left in them were piled up one on another at a different location in the yard. In 21 days the 11 boxes were shaken again, and gave me another colony. All together there were 5 colonies from 11 box hives. All these shaken colonies averaged about 75 lbs. of clover honey per hive. July 25 these colonies were supplied with good Italian queens in place of the black ones. Owing to considerable outside work at this period I did not treat every hive with frames by the Alexander method. The bees in the outyard that were given the plan turned out well. But as the season advanced toward midsummer I did not dare to take a queen out and leave the hive queenless for 27 days, because I feared a heavy winter loss. So during the month of August every colony that had not had treatment for foul brood was requeened. There were in August seven colonies diseased badly. This season I shall watch these very carefully and see if the Italians cure the disease alone. I know that this method will not cure the disease to any extent, but the good stock will help to keep the disease under control.

To return to the one Italian colony: Its total number of sections last season was 190. It seems almost wonderful to think of a colony producing this amount with foul brood on every hand. The two clean swarms in the outyard produced 274 finished sections besides two sets of combs. Both of these were, by the way, worked on the Doolittle plan for comb honey, while the one in the home yard did not even offer to swarm until the bees started supersedure cells later in the summer. So by the buckwheat flow

the total number of colonies in the yard numbered 32, and each of these had a fairly good Italian queen.

When I began to take care of bees, and for a few years after, I thought it was fine fun to watch for swarms and then chase the little fellows around in the tree-tops in order to hive them. But in the last season or two experience made me change my mind. It was the custom in most cases to lose a few swarms each summer; however, by the "shaking" method this trouble took care of itself; and the best part of it was that the colonies so treated made so much more honey in return for the extra thought. By the Doolittle plan for comb honey I can receive three and four times as much as by the older methods.

For a number of years I have been using the Alexander plan for building up weak colonies. In fact, I have never lost a colony by it yet. This is one of the many good plans that one comes across by reading the bee journals and keeping close up with the times.

A word to the beginner might be helpful. Some in the first stages of bee fever do not use full sheets of foundation in both sections and frames. After one has tried full sheets, no one can hire him to go back to starters again. The section boxes which I use are split one side and filled with a full sheet of extra-thin super foundation. The sheets are waxed in on three sides in accordance with the Yoder plan described April 1, 1908, p. 431. The split of the section comes at the top and leaves a bee space at the lower edge of the sheet. Sections filled with honey after they have been prepared in the above manner seldom break in transit.

My home yard is about three-fourths of a mile from the western shore of Seneca Lake. Woods and vineyards stretch along the shore in both directions, and sometimes as far as half a mile inland; so the limit of forage in the lake region forces the bees to go in other directions for honey-producing plants. Our main crop here is derived from clover and raspberry, while buckwheat sometimes yields a small surplus in a good season. However, we count ourselves lucky if the bees gather enough of that for their winter stores. But, on the other hand, five or seven miles to the west, and sometimes even north, numbers of acres of buckwheat bloom each year, and from all appearances the clover has equal strength; therefore you see at once why I favor outyards. The only outyard which I have at present occupied with bees is but a mile and a quarter from the home yard, and in reality consists of a small overflow from the latter.

Dundee, N. Y.

Fifty colonies kept in the center of a village.

BEEKEEPING AS A RECREATION AND SIDE LINE

BY MRS. G. W. BARGE

We do not keep bees entirely for recreation; but we do keep them as a side line, because Mr. Barge is fond of caring for them, and has had bees more or less for about twenty years. His real work is in the cold-storage business; but as that does not take all his time except during two months in the spring, when storing eggs, he spends his leisure time in caring for bees.

We have at present about 250 colonies, but have always had the greater part of them out on shares until this summer. The man who has had them because of old age and poor health became unable to care for them any longer, so Mr. Barge hired a man to help, and will take care of all of them himself. He usually keeps about fifty or sixty colonies here at home; and as the queens are all clipped we are not troubled by swarms clustering in the trees as we were before this was done. When a swarm issues, Mr. Barge catches the queen and moves the old hive away, putting a new one in the same place. The bees soon go into it; and if there is no one here to attend to them, of course they go back to the old hive.

Our house is situated nearly in the center of the village; but as the grounds are

large, being three lots, $66\frac{1}{2}$ by 120 feet, the bees do not bother any one much. You can see from one of these pictures that they are gentle, as the little boy sitting on one of the hives was a little fellow from Milwaukee who had never seen a bee until he came to visit us; but as he is very fond of honey he was quite interested in them. He was only three years old at that time, but walked around among the hives without even a hat on, and did not seem to fear them at all. He is now six years old, just as fond of honey; and last summer when he was visiting us again his aunt addressed Mr. Barge as Mr. B., and he said, "Mr. B., from the bee country;" and since then he often calls him that.

At present all the yards, of which there are two besides this, one a mile north of town on our farm and the other a mile south, are run entirely for extracted honey, as it does not take so much time to do this; and the last few years the honey has not come in fast enough to make a success of comb honey, as there were too many unfinished sections.

We find that people, especially farmers, are using honey more and more, and we do not have any trouble in disposing of the greater part of the crop right at home. Several customers among nearby farmers take three sixty-pound cans each year for their family use. They do not consider it a

Mr. G. W. Barge, Union Center, Wis., who keeps about 250 colonies in addition to managing a cold-storage business.

luxury now as much as formerly, and nearly all children are fond of it—at least, judging by the number of them who come here to get what they want to eat at extracting time. One of these views shows the honey-house and the hives between that and the cold-storage building which faces on the street, so these are in quite a sheltered place. The trees shown in this picture are mostly apple and plum, with one basswood. The other view is on the other side of the house, and shows the row of hives along the arbor-vitæ hedge which divides the garden, barn, and chicken-yard from the lawn. There are about a dozen basswood trees in the yard.

STUDYING A SWARM FOR RECREATION

Bees as Vibrating Molecules

BY EDWARD F. BIGELOW

Is there any fact in all the realm of nature more marvelous than the phenomenon expressed in the words, "the vibration of the molecules," of which we all see some of the results while none can understand the cause? We know that a mass apparently solid is not really solid, but that the molecules composing it are in constant and rapid vibration. We can soften the body, we

can lessen its solidity; we can, perhaps, liquefy it, and of it form a larger body mass by forcing the molecules further apart and giving them a wider are of vibration. The blacksmith is familiar with this fact, though he may not stop to reason about it, nor even to contemplate the wonderful phenomenon that takes place in his forge or under his hand. When he wishes to enlarge a band of iron, as, for example, a tire for a wheel, he heats it, slips the hot band around the wheel, cools it by a stream of water, and so binds it firmly in place. A similar phenomenon may be observed on the railroad tracks, where it is necessary to leave a little space between the ends of the rails to allow for their lengthening under the hot sun of a summer day. Every rail is a little longer on a summer afternoon than it is on a winter noon. Heat expands and cold contracts, and only a moment's thought will assure us that, if a body is larger when hot than it is when cold, it must be of such composition that we may term it "loose," and that the molecules will fly apart under the application of a high temperature. We seldom stop to think that a stone, a piece of iron, a piece of metal, or even a piece of wood, is really made up of an almost infinite number of infinitely small particles held together by a force that, for lack of definite knowledge, we call cohesion.

So when I see the small swiftly moving

forms of insect life darting hither and thither as at the swarming of the honeybees I ask, "How is it that they do not bump against one another?" But wonderful as is the fact that they can fly so swiftly and yet each in its own undisturbed and undisturbing path, how much more wonderful is it that, when they are massed together, they can freely move in and out, and that the whole mass, though it be a foot in diameter, is not only supported as a single body by the clinging legs, but any one bee in that mass may go out or go in, may change its position at will, and do so apparently without disturbing any other bee in the cluster! Here are visible vibrations of an astonishing mass of mammoth living "atomies" that compose the compact cluster that we know as a colony. We think it a wonderful feat when we see athletes clinging together in some picturesque form; but how much more wonderful would

it be if they could for hours retain that form, and if each could freely change his position and move freely among the others! They may build up, they may cling together for a minute in the form of a pyramid, of a cross or a harp, but every one within that mass must keep his place and remain motionless. But bees can form a mass of variable form, sometimes resembling the letter W, again the letter M, but more frequently the letter V; and that this mass has its constituent particles of insect life perfectly and actively interchangeable is the amazing fact. I do not recall that in any book or magazine pertaining to bees that I have seen, this astonishing fact is mentioned; yet to me there are few things pertaining to honeybees so astounding. Though we may not be able to explain how it is done, to see the thing actually done is more than

Spending a comfortable afternoon with plenty of company.

interesting. For that purpose, go to the swarm, without glove and veil, approach so near that each member of the group is singly visible, then here and there gently separate a little mass; note how they cling, note how freely they move one over another; how, perhaps, a dozen supporting a hundred below can freely travel over the dozens that are above, and at the same time each of the hundred below and each of the hundred above is traveling swiftly in and out of the cluster, with no apparent notice from its associates. Here is a new field for a study that should be done not so much in the hope of solving the problem as to witness the astonishing performance. Remove a small mass from the cluster, hold it on the end of your finger and see how the bees cling together.

The accompanying photographs show the

Finding out how the "molecules" of the swarm body move freely about.

writer investigating the movements, although in one of the two poses his bald head is perhaps more conspicuous than the colony of bees. I suggest to the veteran beekeeper that, if he wants to interest boys and girls in bees, he may make the subject far more attractive if he will tell them of these movements with special stress on the individual independence of each constituent insect. That will be better than to lay so much stress on the fact that they produce something that may be sold or is good to eat. Here is food for thought. The brain and heart are more valuable than the stomach or the pocketbook.

Arcadia, Sound Beach, Ct.

MOVING 250 COLONIES 210 MILES

BY J. L. BYER

Mention was made in the June 1st GLEANINGS about my plans to move a large apiary some 200 miles from my home; and in view of the fact that a number have written me asking how we got along, I am prompted to give a write-up of the trip, not with the intention of being able to say any thing original on the subject of moving bees, but rather with the thought that perhaps somebody may have similar work to do in the near future, and may be able to get some

slight help by reading about the experiences that naturally occur on a trip of this kind.

Briefly, the problem before us was something like this: 250 colonies of bees with about 500 supers of extracting-combs, storage-tanks, barrels, extractor, uncapping-cans, etc., situated 200 miles from home, all to be prepared for moving, hauled three miles to the station, for a trip of 260 miles by rail, and, in the end, to be hauled a mile and placed on stands in their new location.

The first thing to do was to formulate plans to carry out the work successfully. It is needless to say, considerable study was spent on the matter for a few weeks prior to the trip. Many of the bottom-boards were none too solid, so I had a number made at home and shipped down a week before I went myself with a man to help me. Then the question of ventilation had to be decided upon, as *ventilation* and *water* are the two prime requisites in order to insure good results in moving bees by ear lots in warm weather. As I had 90 screens on hand from last year's trip I utilized them; but for the rest I decided to use cotton on half-depth supers. Screens and cotton were shipped ahead with the bottom-boards.

We left home on the 14th of May, arriving at our destination about four in the afternoon.

A hasty glance was taken over the bees. I had not seen them since early last September. Then we started at once to nail on bottom-boards. We had crating-staples with us, but they did not make things secure enough to suit me, so we used four nails in each bottom-board, nailing right up into the hives—the very thin nails called “box nails” being used for this purpose. This kept us going all day, and it was the heaviest work of the job stooping over and turning the lives up—an awkward position that becomes tiresome after one has been at it for a long while. The next day it rained all the time; but we were not hindered at all, as we fastened the cotton on the supers, strips sent down with the screens being used for this purpose. The next day, Saturday, my assistant was put to work fastening on the screens and supers covered with cotton, while I helped a good farmer friend to prepare a rack to haul the supers to the station, and we started at the work at once.

Fig. 1 shows the rack as we prepared it for moving supers, and, needless to say, it was ideal for the purpose. This wagon also took a load of bees at night, 36 hives going in one tier. The supers were packed full of comb, a number then being left empty (full supers do not give any chance for the combs to drop out). With this big rack we

were able to haul nearly all the supplies in three loads, and it surely saved a lot of time and expense, as the stuff was more bulky than heavy, and it was a question of how much we could get on, not how much could be drawn. An obliging railway agent had ordered cars for me two days before I needed them, so we started to load the supplies on Saturday, intending, if all went well, to load the bees Monday evening. On Saturday evening, in company with my good farmer friend Mr. H. Kendrick, I asked a number of farmers to help me move the bees; and, although none were familiar with bees, every man I asked consented at once to help me. As there were no spring wagons in the community, I decided to get them to bring their hayracks, first placing rails or scantling around the sides about a foot higher than the sides, and then placing hay on the rack about 18 inches deep. Of course, when hives were on the hay it would settle down lower than the sides fastened on the rack. This arrangement proved first-class, and I really believe it is better than most spring wagons.

Two cars were procured—one an ordinary stock-car, and the other a double-decked one. All supplies were put above in the upper deck; and, while the plan worked well to save space, the cramped position one

A closer examination.

A swarm of bees can break down a tree (if the tree isn't too big and the swarm is large enough).

has to work in while loading will certainly put a crimp in his spine as quickly as any thing he can go at. I know from experience all about that part of it. Every thing was firmly fastened in this upper deck, as one always has to prepare for rough usage, even if he does not happen to get it.

All of this work was done by Monday at 4 o'clock P. M., and in the evening the real work of moving the bees was to start. Farmers were asked to be there by 7 P. M.; and before that hour a few of them had arrived. Strips of lath were all ready, one at each hive, so that, as soon as the bees stopped flying, the entrances could be closed. An inch nail at each end was used, and it was a short job to close entrances, one man doing it as fast as the loading was done. Wagons were brought as near the yard as possible, and I insisted that teams be removed while loading, a plan I have always followed when having help to move bees. Mr. Kendrick took charge of one wagon while I mounted another; and as the helpers carried the bees to us, we put them in place. Eight wagons took the whole outfit; and so nicely did every thing work that in less than an hour from starting we had the lot—241 colonies, to be exact—all on wagons ready for moving.

Then the trip started; and I regret that,

owing to its being dark, I could get no picture of the procession, as I never expect to see just the same scene again. The road to the station was fairly good, but a little rough, as most of it is on solid rock. I walked back and forward all the time from one wagon to another, but all arrived safely at the cars about 9:30. I stated that all supplies were put in that upper deck; but I forgot to say that a tier of full-depth supers filled with combs—about 160 of them—were placed on the bottom of the single-deck car, and then the bees were placed on them. They rode perfectly, thanks to R. F. Holtermann for the suggestion before I left home.

Just a word about how the bees were placed in the cars and the

provision made for watering them. At each end of the car about six inches of hay was packed between the first row of hives and the end; and as we loaded from both ends of the cars any space left at the center was also packed with hay. This is a splendid "buffer," and takes nearly all of the jolt from the hives. Of course the hives were loaded with the ends of the frames facing the ends of the cars. Last year I used 60-pound cans for carrying water, and ran out of this necessary article while on the road. It was a nerve-racking business getting water along the road, so no more of that for me on another trip. This time 60-gallon barrels were prepared by having a hole 10 inches in diameter cut in one end. These barrels were filled at the station pump, and, with lots of help, were lifted into the car after every thing else was in, standing right at the doorway. With a dipper one could reach any hive in the car quite easily, although a large veterinary's syringe, holding about a pint, had been provided for the double-deck car. It was not necessary, though, as even in that rather limited space a dipper worked to perfection. With a hole in the center of the barrel there was no splashing out of the water—in fact, I sat on top of the barrel on a cushion most of the time while on the trip.

The bees were all loaded without a single mishap about 10 P. M., and, needless to say, we were tired, even if not aware of it at the time.

No freight went from Bellamy to Smith's Falls till the next evening at 7, so we expected a weary wait all the next day before going that 17 miles that lay between us and the main line. But again fortune favored us; for when the bees were about loaded, my good friend the agent already referred to came around to the car and told me that he had been busy on the wire with the train despatcher and other officials, and they had ordered the fast express that went up at 7 A. M. to stop and pick us up. My suit case and the "grub" for the trip were back at New Dublin, and that meant that I must go back to get them that night. I went back with one of the teams, stayed there over night—i. e., what little of the night was left—arose at 4 A. M., and walked to the station, carrying my suitcase and box of provisions, weighing about ten pounds, I suppose, but really seeming more like 50 before I got there.

Sharp at 7 the next morning we pulled out on the express, and were soon in the yards at Smith's Falls. I promptly looked up the yardmaster, and he at once consented to place my cars on a switch where they would not be touched till ready to leave. Two trains left before noon; but as they were both to do some shunting along the way he advised me to wait for the fast freight that left at 1 o'clock. His advice proved good, as we passed the other freights before getting to the next divisional run at 7 that night. The cars were next to the engine—a very important item, as there the bees get handled much easier than back at the end of trains of 18 or 20 hundred tonnage, as all trains are on that line.

We pulled in at the first divisional point at 7, and the engineer insisted on placing those cars himself, and not allowing the yard engines to touch them. Forty miles from that line we had to leave the main line and go over 100 miles on a new line completed only last fall, and I learned that no train went up that branch line till one

FIG. 1.—A load of supers filled with combs on the way to the depot.

left our station at 6 the next morning. The night was cool; and as the bees were quiet we went with the agent at that place for the night, arranging for a call in the morning. The agent formerly lived near us, and it was another pleasant surprise to find him there and to have him help us. At 5 the next morning a messenger came to the house and asked if the man with the bees was there, and we were told that the train would be ready about 6:30.

After another pleasant trip that day we arrived at our destination at 7 that evening in a pouring rain, so the bees were not unloaded till the next day. The morning was cool and cloudy, so from start to finish we had nothing but the best of luck in every way. The engineers on both long runs were splendid fellows; and although I was more than willing to make it worth their while to handle the cars gently, they did not look for it like some who are always watching for tips. However, it pays to start on a trip like this with a dozen or so quarters in your pocket for judicious use along the way. As stated, we had our lunch with us; and although finger-bowls and table-napkins were not in evidence, we managed all right.

Just a word as to how the cotton served us for ventilation purposes. In my opinion it is away ahead of screens in every way; for, strange as it may seem, it actually gives more ventilation than the screens, and the bees are quieter. With the wire cloth they see too much light, and are all the time flying to the top and trying to get out, while with cotton they rarely fly up at all. As to

FIG. 2.—The apiary before the hives were prepared for shipment.

water, we struck fairly cool and moist weather, and did not use half of the supply, but that was better than not having half enough. Not a comb was broken nor a pint of bees lost, neither did any larvæ die, so far as we could see.

Picture number 2 shows part of the yard before the bees were prepared for shipment.

Fig. 3 shows the bees in their new location, four rows with 60 in each row. To the north of the two houses are 120 colonies that wintered on the spot—a few of the hives being seen in the distance. Every hive rests on broken rocks taken from ledge that shows in the distance.

Was I tired after the trip? Yes; and yet after all I can not say but that the work was pleasant, owing to every thing going so nicely; and while I am not looking for a steady job in moving bees by train, nevertheless I would not view with any great alarm the prospect of moving another car-load some time. It means a lot of careful planning and always being *sure* that all is right. In this job, above all others, it does not pay to trust too much to luck. With all our careful survey of hives to see that there were no holes for bees to escape, now and then a wormhole or other small opening would let out a bee or two. A roll of cotton batting at each wagon while loading, and, later on, in each car, was a ready and handy way of stopping up such leaks, and I do not think that a man outside of my assistant and myself was stung during all the work in the yard and at the cars.

Mt. Joy, Ont., Canada.

AUSTRALIAN NOTES

Kerosene-Cans Prohibited for Putting up Honey

BY F. R. BEUHNE

In endorsing the statement of Mr. W. Barnes, p. 705, Nov. 1, made in refutation of one by Mr. M. Shallard, p. 455, July 15, that "Practically the whole crop of Australian honey is put up in second-hand kerosene-cans," I wish to add that the use of any other than new honey-tins is prohibited in the State of Victoria by the Board of Health regulations gazetted Oct. 9, 1912. After the close of the present season this regulation will be strictly enforced.

QUEENS LAYING ABOVE THE BROOD-NEST.

Mr. M. Shallard, p. 798, Dec. 15, 1912, says that a good strain of Italians will not lay above the brood-nest. Well, I know a few good beekeepers in this part of Australia; and out of the lot I have heard of, there is only one other who wants the queen to be confined to one set of combs. I follow the example of most beekeepers by pinching the head of every queen which does not put brood into two stories in spring. One can not secure a strong enough worker force from one set of brood-combs (Langstroth) to get the best returns. In the apiaries giving the highest yield, hives are tiered up three and four stories high without a queen-excluder. In a letter received Feb. 1 from Mr. Ballinger, who is running an apiary on shares with me, the yield of one four-story hive for the month of January is given: Extracted, Jan. 7, 90

FIG. 3.—The apiary in the new location, four rows of 60 colonies each.

lbs.; Jan. 17, 120 lbs.; Jan. 24, 90 lbs.; Jan. 31, 90 lbs.; and still going strong. This total of 390 pounds for one month could not possibly have been gathered by the bees from one single brood-chamber. There is no need to restrict the queen; if her workers are as long-lived as they should be, there will soon be so many honey-carriers that they themselves will restrict the egg-laying by filling the cells with honey.

Since writing the above, my son, owing to a serious accident to Mr. Ballinger, has gone there to run the bees till Mr. B. has sufficiently recovered. My son writes that the yield of the eight best colonies from the beginning of January, when the flow commenced, to February 14, is as follows:

Hive No. 51, 600 lbs.; hive No. 260, 600 lbs.; hive No. 75, 480 lbs.; hive No. 18, 600 lbs.; hive No. 248, 540 lbs.; hive No. 205, 540 lbs.; hive No. 127, 540 lbs.; hive No. 256, 480 lbs. Total for 45 days, 4380 lbs.

The honey was not weighed but measured, being drawn straight from the extractor into 60-lb. cans.

These are, of course, the best colonies, and the general average for the 100 colonies in this apiary will be considerably lower; but it should also be stated that four-fifths of this yield came from one variety of eucalyptus—red gum (*Eucalyptus rostrata*), and that the bees are still going strong, now on white gum (*E. viminalis*) and messmate (*E. obliqua*). The figures, however, do not by any means establish a record. The season before last, one apiarist who is located about 40 miles south-

west from this spot obtained an average of 480 lbs. per colony for 220 colonies. Now, could a one-story queen produce sufficient bees to gather this amount of honey in the short space of 45 days, as in the case of my own apiary?

GIVING A COLONY HAVING A VIRGIN EGGS IN ORDER TO HASTEN HER EGG-LAYING.

I am greatly interested in this Miller versus Miller and Root controversy on pp. 788 and 796, Dec. 15. So far Mr. Arthur C. seems to have the best of the argument; but on second thought I am not so sure about it. For about ten years I have reared many of my queens in both nuclei and full-sized colonies with an aged queen laying continuously in the combs on which the young queen roams at large till she herself is laying. She is then removed, and after a week's interval another cell is given, and the process repeated throughout the season. Early in the spring I exchange queens between colonies having a three-year-old queen and nuclei with previous season's queens. Thus the young queens are made the best use of in the full colonies, reducing the swarming tendency at the same time, while the restriction of egg-laying produced by transferring the old queens to nuclei makes them last through the season. In fact, I have several now in their fourth year.

With an old queen still laying in a nucleus after a young laying queen is removed, and while another virgin is maturing, there is no need of giving either eggs or brood, as there is always a laying queen

Bee demonstration by the Ontario Department of Agriculture at the apiary of J. E. Fair, Haldimand Co., Ontario, Can. Photographed by R. F. Holtermann.

there. Now if, according to Mr. Arthur C., "The presence of eggs and larvæ bespeaks to the bees the presence of a laying queen, and probably conveys the same information to the virgin, and the normal reaction follows," what I should like to know is why the same result does not follow in the case of the nuclei with old queens; and why do bees frequently start queen-cells within 24

hours after the removal of the queen when (owing to the presence of eggs) they should not miss her for three days. Further, many of my queens are mated from upper stories with a laying queen below the excluder; and while taking care to leave each queen in her own compartment I frequently exchange combs between the two stories and yet my loss of virgin queens is only from

Mr. James Armstrong addressing the Ontario field meeting (Mr. Armstrong is standing with the frame in his hand. Mr. O. L. Hershiser and Mr. R. F. Holtermann are seated just at the left). Photographed by R. F. Holtermann.

FIG. 1.—Geo. Fetzer's work-shop and house apiary.

two to three per cent. Years ago it used to be much heavier; and after reading the "egg-giving controversy" I remembered that I used to give each nucleus or colony a comb of eggs and brood, not to induce the queen to lay sooner, but to see by the presence or absence of queen-cells whether the queen had been lost in mating when examining the nuclei for laying queens on the tenth or eleventh day. Well, this test proved a failure because I would often find cells started, and the virgin queen being chased about on the combs by the bees or balled. It did not occur to me at the time that the giving of brood might be the cause of the treatment of the queen. I merely abandoned the plan as unreliable.

After reading page 796, Dec. 15, 1912, I decided to make another test. I had ten queens which had hatched a week before. Eight of them I found were already fertilized, but two had not mated. Into both of these hives I put a comb of eggs and larvæ from which every bee had been brushed. Twenty-four hours later I found that one queen had disappeared, and that the other was being balled. I dispersed the ball of bees with smoke and removed the comb of brood, and four days later that queen was laying. Of course one swallow does not make a summer; but at the same

time this is the only case of balling a virgin out of 150 this season, and the only way in which I can reconcile it with the experience with the nuclei, old queens, and the virgins on combs of eggs and brood above the excluder but from the same hive, is that it is not the presence of eggs but the addition of eggs and larvæ with the odor of another colony which causes the trouble. But if one of the Millers tells me that the odor is conveyed just the same by a comb containing only older and sealed brood, and which does not cause trouble, then I'll withdraw that theory in favor of a more feasible one he may bring forth.

Tooborac, Victoria, Aus., Feb. 28.

BEEKEEPING IN A CITY OF 60,000 POPULATION

BY GEORGE REX, JR.

The subject of my sketch is George Fetzer, who lives in the city of Allentown, Lehigh Co., Pa. He is about 60 years of age, a retired florist, and at present is interested in real estate; and out of pure love for the little honey-gatherers he is a devoted beekeeper, having about 30 colonies on several city lots, less than 50 feet from a street, and only a short distance from an alley with rows of houses only a few hun-

FIG. 2.—Geo. Fetzer's apiary in Allentown, Pa., a city of 60,000 population.

dred feet away. He says that he never has any trouble with his neighbors about the bees. He has all his bees, except six or eight colonies (which he recently purchased cheap), in ten-frame Langstroth hives, as he is an advocate of large hives, hence large brood-chambers and early brood.

The pictures were taken Jan. 1, 1913, and Mr. Fetzer thought that some of his queens had begun laying already, owing to the warm open winter. Mr. Fetzer does much winter feeding to stimulate the bees and to urge early brood-rearing. Bees were flying when pictures were taken. Snow had fallen before Christmas, followed by sleighing; but on New Year's day the temperature was about 60 in the sun, with bees flying, and his yards suggested a summer scene.

Fig. 1 shows his work-shop and bee-shed combined. The front sides show a number of windows, inside of which he has a hive. In extremely cold weather he can close the windows, insuring warmth for his little friends.

Fig. 2 shows his outdoor bees. They have no shed for protection. The picture indicates plainly how he has them arranged and put up for winter. In the background we seen several rows of houses showing how near they are located to his apiary. Mr. Fetzer works both for comb and extracted

honey, and got a good crop from each for 1912. He finds ready sale at the various grocery stores in Allentown, getting 18 cts. for fancy white comb and 40 cts. a quart for extracted (wholesale).

While there taking the pictures, an old gentleman came to Mr. Fetzer for the rheumatism cure, and he accommodated him by letting three or four bees sting his rheumatic hand. Noticing that he had quite a number of discolored marks on his hand I inquired, and was told that he comes to be stung several times a week, and that it benefits him greatly.

Stettlersville, Pa.

BEEKEEPING FROM A SCHOOLTEACHER'S STANDPOINT

BY CLARENCE FOOTE

As a teacher in a rural village school and as a beekeeper I have found several advantages for those engaged in the teacher's profession in combining the two vocations, and will show how close a connection exists between them. The principal advantages in beekeeping as a side line, and those which interested me most are the financial returns, natural qualifications of a teacher

A rural teacher invariably makes a good Leekeeper.

for the work, the healthfulness of the work, and the knowledge derived, a source of enthusiasm to both teacher and pupil aiding the teacher in understanding his pupils.

In thinking of the teaching profession in the rural schools, I recall an address made by a certain normal-school principal not long ago in which he said he believed the old adage, "Teachers are born and not made," was not so in the original, and a fault of the typesetter, for such a saying has not been always true. He thought the saying should have read and probably did read, "Teachers are born and not *paid*," for then it would be true in a practical way.

The teacher is not only poorly paid, but in most cases his position lasts only eight months of the year. He must then take up some other line of work during the summer season. Beekeeping affords a lucrative employment for the summer vacation time as well as for Saturdays during the other parts of the year.

The teacher represents, as a class, one of the best mind forces of the country. With his natural tendencies toward science and experiment, the modern pedagog would surely not retard the rapid progress in apiculture. With the present-day curriculum in the schools the subject of nature study has become compulsory, and the bee must be studied to a certain extent. The economic value of the bee has also to be brought out in connection with the proper pollenization of fruit-trees. Then, too, their habits have

to be discussed. In this way considerable knowledge is required of the teacher about the honey-producing insects in order to give the proper work for the children under his care.

The teacher who has been in the school-room for eight months does not feel, from point of duty to himself and his schoolwork for another year, like taking up a position in an office during the summer, and in a large number of cases does not feel like hiring out to a farmer to do all of his hard work for him. What he wants and needs is the open air, and this he can get by owning a small apiary and by working his yard intensively. This would be much better than owning more bees, as it would pay better for the money invested.

By having his bee-house and work-shop below the colonies the honey could be easily wheeled to the extractor in small quantities without expending so much vital energy as would be the case without a wheelbarrow or hand cart.

Then, again, many teachers, among them myself, are afflicted to some extent with rheumatism. They are often cured by the stings of the bee. By this I do not infer that every case can be cured by the method given; but at any rate, from my own experience I have found that, when I am away teaching, I often have a touch of the disease; but on coming home on vacations or in the summer I am not troubled in that way at all. Further, on looking into the matter I find that the hospitals in the local

Drinking to the health of the bees and their hostess.

cities use the remedy for certain cases, with almost miraculous results.

Still another reason is that the thoughts of the teacher are taken completely away from the cares of teaching. This is brought about by the "bee fever," with thoughts only of "bee lore" filling his mind.

The knowledge derived from beekeeping can certainly be made a source of enthusiasm to both teacher and pupil if the same amount of tact is used in arousing interest as in the other subjects. In other words, it brings about better harmony in the school-room, with less effort on the part of the teacher. Thus the schoolmaster uses a valuable asset that counts toward success in his career.

One who has learned the principles of nature by a close observation of the inmates of the hive will be greatly aided in understanding the different traits of character exhibited in the children, and will be much more ready to cope with the many difficulties that are sure to come up for solution. This readiness is often important, as every teacher knows in school life.

My building in which I do all inside work is 16 x 20 ft., and a 1½-story structure. It is located in an apple orchard with slope toward the south. The lower floor is concrete to prevent rats, mice, or other rodents from destroying supplies.

I have my four-frame reversible extractor on a platform a foot higher than the concrete floor. The honey-tank is on the same

elevation for convenience in drawing the honey off in pails. The uncapping pan and melter is similar to the Peterson, now so popular with beemen, though much smaller. It is heated by means of a one-burner oil-stove.

I have 18 colonies, spring count, although by actual numbers I have more than that, made by artificial increase to prevent swarming. I wintered them in father's house cellar with excellent results. No feeding was done, as the fruit-trees were in bloom two weeks earlier than usual this year.

Delanson, N. Y.

BEEKEEPING A RESTFUL AVOCATION

"Bee Parties."

BY MRS. CHARLES STEWART

Having mastered the A B C of beekeeping I am now deep in the mysteries of X Y Z. After several unsuccessful attempts at queen-rearing the bees finally accepted the artificial cells in a manner exceeding my wildest expectations; but for some unaccountable reason they brought to maturity only one queen, and the bees in the mating-box put an end to her. This did not discourage me, however, as it was an improvement over all former attempts, and gave me experimental work with nursery cages, mating-boxes, etc., that must eventually result in success.

To my mind, scientific queen-rearing is the very acme of apiculture, and my joy will be complete if I can successfully work out this problem.

My apiary consists of 19 colonies. But few are in prime condition, and making surplus honey; but I am having lots of fun in the apiary studying and experimenting. As a recreative agency I must say apiculture is without a rival.

Work? Why, yes; even with an apiary of 19 colonies there is work connected with it, and some hard work; but as some one has said, "A change of occupation is the best sort of rest." "Push on, keep moving," is a prescribed and well-known cure for the heartache.

With the exception of chasing a swarm, perhaps the most exciting part is climbing to the top of a tall ladder, bringing the clustered mass down from the most nearly inaccessible branch of an apple tree; or, perchance, the queen may have absconded with part of a large swarm a quarter of a mile up the street, the larger part returning to the hive, as I had a swarm do the other day. I pocketed my pride, shouldered a step-ladder and basket, started in pursuit of her ladyship, and brought her back home. I clipped her wings, and will have no more trouble from her till I can replace her with another queen. Of course this swarming nuisance can be avoided largely by clipping the queen; but apart from all this I say there is no recreative occupation affording as large and satisfactory returns in health, real pleasure, and financial profit, as the keeping of bees.

In these days, when there is such a wild search for novel entertainment, the bees too afford a most unique and instructive source.

I have given several bee parties; and,

A few of the ladies of the mothers' section of the Alden Club (Franklin Woman's Club). Introducing a queen direct to a shaken swarm.

following a short informal talk, I find it great sport showing off in the apiary, watching the amazed expression on the faces of my friends, listening to their exclamations of wonder and admiration as, without protection of veil or gloves, I shake a swarm, introduce a queen direct, or do some other easy stunt which seems to the onlooker as quite impossible.

And then the joys of harvest time! You old stagers know the "feel" of it; but to the amateur, as she takes from the supers the well-filled sections of beautiful honey, the pleasure and pride of production is intensified a hundredfold.

To my sisters, the busy home-makers, nervous and worn with the never-ending

Admiring the finished product.

routine of housework, and to those who are devoting their spare time to the "frivolous work of polished idleness" I would recommend the study of bee life and the practical side of apiculture.

Personally I find nothing so restful as an occasional run out into the beeyard—the coziest, most alluring spot on our place, there to spend an hour with my pets. Invariably I return to my work indoors rested, and with renewed interest and energy, my heart singing the glad refrain:

Mine be a cot beside the hill,
A beehive's hum shall soothe my ear;
A willow brook that turns a mill
With many a fall shall linger near.

Franklin, Mass.

WHEN I BEGAN BEEKEEPING

BY EUGENE SECOR

When I married I was anxious to begin home-making in the right way. I had bought a little place in the edge of town (and, by the way, we still occupy it), and began developing it. My father had always kept bees, in box hives of course, back in old

York State, and I knew as much about them as the average farmer of those days. That knowledge was bounded by a few facts pricked and pounded into my head by experience and observation. I knew bees would sting, that they would swarm, and that they would *sometimes* store a little surplus honey in a rough box made of inch lumber on top the hive, the access to which was through a couple of auger-holes through the inch board nailed tight to the top of the brood-chamber.

You may be assured that such practice never secured any white or early honey. By the time buckwheat blossomed, the weather got warm enough and the colony strong enough to build comb in that upper chamber. So about all the honey we ever got was buckwheat.

That's all I knew about bees. But when the spirit of adventure seized me, and I came to Iowa, I was ready for advanced work in the A B C class.

While I was growing up, Langstroth and Quinby appeared above the horizon, shedding a flood of light on the beekeeping world. I had never read their books; but an occasional item in the *American Agriculturist* and other papers always attracted my attention; and when I bought my first colony I sent for Quinby's "Mysteries of Beekeeping Explained," and began studying the natural history of the bee. At that time Mr. Quinby illustrated and gave instructions as to the use of the box hive; but it happened that there lived in my neighborhood a carpenter beekeeper who was making his own hives with the Langstroth idea, but not the Langstroth frame. His hives were about 10 x 14 x 10 deep, as nearly as I remember, with the frames crosswise. I got him to make me one, paying him \$3.00 for it. It was a dandy. It had a cap of gothic architecture, with ventilators in the gables, all painted white, and looked like a bird-house. I gave \$10.00 for a prime swarm to put into it. The hive being small I had plenty of swarms and quite a good deal of comb honey also, for that period.

That was before the days of sections, and I used various styles of honey-boxes, the most satisfactory, probably, being a glass box with corner post grooved to hold the glass sides and ends, and held together by nails in each corner through the cover and bottom of thin boards. Bits of comb were used for starters.

I soon found that the hive I had started with was too small, and made others larger, but with frames crosswise of the hive, after the pattern of the first one. When sections came into general use I changed again to the

Langstroth eight-frame hive, which I have used mostly since. I have used the ten-frame, but not with signal success.

Like a good many other beekeepers I passed through an inventive period, but never had the disease so hard that recovery was long delayed. I made the first honey-extractor I ever used. A half-barrel with a simple home-made reel to hold the frames, two grooved wooden wheels, one about four times as large as the other, a hard twisted cord belt, an upright peg through the outer edge of the larger wheel for power, and a few small wires wound around the reel to hold the frames from flying off centrifugally, and the extractor was complete. And it worked. The chief objection was that, with heavy frames, the belt would slip, starting and stopping.

What changes time has wrought! From the box-hive days of my boyhood to the frame, section, foundation, extractor, smoker, Italian bee, queen-rearing, queen-clipper, etc., sounds like a fairy tale. From a haphazard avocation, a pastime, beekeeping has become an industry, a vocation requiring energy, skill, capital, forethought, and experience. The tinpan method has developed into an art to control and direct and outwit the "Spirit of the hive."

"HOW DOTH THE BUSY BEE?"

She "doth" the best she knows—
Which isn't very much, to be exact;
She rises with the lark, and goes
Skylarking through the countryside,
Trying to wake the drowsy flowers
Before they're through their nap; in fact,
She noses far and wide
Between the showers.

She'll never see her first birthday,
But keeps right on
As if she'd come to stay;
And, copying forbears gone before,
She does a lot of work for naught;
When balm o' Gileads bud, anon
She brings a store
Of gum she hadn't ought.

She likes a hollow tree
In spite of dovetailed hives;
And she'll sting you or me
Who feeds her just as she will sting a bear
That robs her nest through greed.
She isn't wise beyond compare,
But does know how to make a seed.
Forest City, Iowa.

HONEY A CURE FOR SICK HEADACHE

BY MRS. J. R. DARLING

When I was a child we lived in a small house on a large lot in a little village. The country was beautiful, and my thoughts have often turned to the woods, meadows, and streams of my childhood home. As

we children carelessly played in the woods we often kidnapped a bee from some flower. I remember just how they looked as they would crawl out of my closed hand. What might we not have done with a few hives of bees if we could only have realized the opportunity which was ours!

When very small I became subject to sick headache. Father often had it, and I supposed it was my lot by inheritance. We moved to Kansas, where I married a Kansas farmer. I raised some chickens and turkeys, wishing to add to our income, but those dreadful headaches soon became entirely too familiar.

Later we moved to Minnesota, where the sight of bees and acres of wild land covered with flowers awakened in me a desire to try stocking our table with honey. And now this big brave husband of mine, who had ridden all the wild bronchos that came through our part of Kansas, and had often boasted that he was afraid of nothing, made various excuses about not wanting bees on the place because of their tendency to sting.

Of course I gave up, but still I longed to try keeping bees.

One day I learned that a Swede neighbor living across the lake from us had bees, and I began to negotiate for a colony, which he promised me for two dollars. In order to secure the consent of my English husband I promised to care for the bees; and our neighbor said, "Leave them alone and they will leave you alone." I also promised never to sell a pound of honey which we could use ourselves. I gained his consent; but as it was then late in the season I did not get my bees until the middle of the next June.

The next morning after the colony was moved to its new home we were proud and happy to see the busy bees at work. Two days later, while hoeing in the strawberries in front of the hive, one of these dear little fellows stung my husband on the eye. This either cured him or else his terror was pretended, for he has never seemed to be very much afraid of them since. Nearly all of us were stung some time during that summer. We got no honey, and had to feed the bees in the fall.

The next spring I was anxious to save all the swarms, so I began early to fret and stew, and by May 10 I had two extra hives at my command. All summer those hives mocked me, for they remained empty, while the original colony laid up all of 24 pounds of honey. It was good, and I still hoped. My "better half" enjoyed teasing me better than he would have enjoyed eating any quantity of honey. In spite of it, I kept up hope, and the next year a fine swarm

came off and with great excitement was hived.

In the fall I found my credit column looking well; for the parent hive and the new swarm had given us an average of 65 sections each. We were now eating honey; and as the weeks went by I began to wonder where my sick headache had gone. No amount of eating seemed to bring on an attack. Our family is large, and the honey was gone before spring came. The headaches returned, and I awakened to the fact that I had the bees to thank for a cure for sick headache, which could never be valued in dollars and cents. On July 8, 1912, I took off my first section of last year's crop, and to this day I have not had another attack of sick headache. Last year we started with two colonies. They increased to 6 and gave us 226 sections of comb honey.

Lifting is no problem, as the children are always glad to assist in the summer, and my husband helps put them away for winter. That is, he carries in the hives and I go ahead to open the doors and clear the way. We keep little folks from the hives by using low woven-wire fencing. We have never had a swarm cluster high; and our experience so far has been only play; but we mean to stay in the business.

Aitkin, Minn.

WHY HONEYBEES DO NOT GATHER NECTAR FROM SWEET PEAS AND GARDEN PEAS

BY JOHN H. LOVELL

The relation of the honeybee to the garden pea seems to be a question of considerable interest, not only to beekeepers but to farmers and students of flowers. Last summer I looked into the matter carefully, and herewith submit for your consideration an account of the results. I also enclose a drawing of a flower of the pea family, as there are probably many who are not familiar with the general structure of these flowers. A very large number of honey plants belong to this family. While it is desirable to know what flowers are not pollinated by the honeybee, especially where they belong to cultivated plants, yet they are so few in number that they hardly affect the importance of these insects as pollinating agents.

The sweet pea is the most popular of cultivated flowers. The garden is rare indeed in which it is not found; and we have heard of one enthusiast who would cultivate nothing else, but he grew varieties of every color and form. To obtain the best results the seed must be sown in a different soil every two or three years. This is not so much

because some food element has been exhausted, for this could be easily resupplied in a prepared fertilizer, but because the roots excrete some substance which is injurious to the plants and prevents the roots themselves from properly doing their accustomed work. There are many who put up a permanent trellis and grow their sweet peas in the same location for a dozen or more years. They often complain of the want of vigor the vines exhibit, and of the scarcity of the blossoms. Let them sow the seed in a new place and note the results.

There is something wanting in the spiritual makeup of the person who does not experience pleasure in beholding the brave display made by these beautiful flowers. They exhibit every hue from white to purple, while the individual flowers are often variegated. The fragrance is strong and sweet, suggestive of honey. In form they are shaped like a butterfly. They contain nectar, and are produced in great profusion. Surely we should expect to find them swarming with bees.

But you may examine them day after day, and not find a single insect on the flowers. During the past summer there was a row of sweet peas within fifty feet of my

Fig. 1

Fig. 2

FIG. 1.—A flower of the pea family (*Papilionaceae*), after Gray. a, the standard, a large broad, high-colored petal to attract attention; b, b, the wings on which the bee stands; c, c, the keel, composed of two petals, containing the stamens and pistil.

FIG. 2.—A section lengthwise through the keel, showing the stamens and pistil in place, all the petals, except one, removed; ca, the calyx; an, the ten anthers; st, the stigma. Nine of the stamens form a tube (t), at the bottom of which lies the nectar; the tenth stamen (f) is free to permit the bee to insert its tongue inside the tube. When a bee, resting its head against the standard, pushes down the keel, the anthers and stigma protrude through its apex and touch the under side of the bee's body.

apiary, in a location where the bees were constantly flying over them. I repeatedly examined the flowers; but during many weeks not a single bee did I observe on them. Why was this? Put a honeybee on a sweet-pea blossom and you will at once see that it is neither large enough nor strong enough to depress the keel, and that, consequently, it can not obtain the nectar.

Neither can any of our Maine bumblebees depress the keel. One day in September I saw a large female bumblebee (*Bombus fervidus*) fly to the flowers, but she did not even make a pretense of trying to obtain the nectar in the legitimate way. Instead she stood sidewise on one of the wing petals, and, thrusting her tongue into a crevice between the standard and one of the wings, she succeeded in reaching the nectar. I watched her while she made twenty visits, and in every instance she obtained the nectar by robbing the flowers. Subsequently she made many additional visits. On another day I saw a worker of *Bombus consimilis* obtain the nectar in the same manner.

Until the summer of 1912 I did not suppose that there was a single species of our native bees which could properly pollinate the flowers. But on September 15 and 22 a female leaf-cutting bee (*Megachile latimanus*), a large and powerful insect, put in an appearance. She easily depressed the keel, thrust her tongue beneath the standard into the staminal tube, and sucked the nectar for a long time. The stigma projected far out of the apex of the keel, touching the brush of hairs on the under side of the bee's body. This brush was loaded with pollen. After she had finished sucking she rested on the flower for several minutes, and permitted me to stroke her with my finger.

But it will, perhaps, be asked, "How do the honeybees know that they can not get the nectar of the sweet peas if they never visit them occasionally. We are apt to forget that the half-hour we watch a flower is only a small part of the day. How much may happen when we are not present! On the morning of August 16 I placed sugar syrup on about ten flowers of the sweet pea. This syrup, as you all know, is colorless and odorless, so that the conditions remained practically unchanged—that is, to bees flying near, the flowers offered no greater allurements than before. They could not discover the sugar syrup unless they alighted on the flowers. In the afternoon I saw two worker bumblebees feeding on the syrup. On the afternoon of August 17 I found three honeybees gathering sugar

syrup, all of which they finally carried away. Thus the syrup served its purpose, which was to detain the bees until I had an opportunity to see them.

By September 22 the honey-flow from the goldenrod was about over, and the bees had more time to look about. On the afternoon of this day I repeatedly saw them alight on the flowers of the sweet pea. They made no attempt to push down the keel. One of them stood on the back of the standard, and probed diligently, but, of course, vainly, for nectar under the calyx lobes. None of them succeeded in finding the nectar through crevices as did the bumblebees.

Even if the honeybee could obtain the nectar, the sweet pea is not sufficiently abundant to be of much value as a honey-plant in most localities. But the garden pea (*Pisum sativum*) in the vicinity of large canning-factories is often cultivated by the hundred acres. Large areas are also devoted to the culture of the edible pea by the market gardeners in the suburbs of large cities. In the flowers I examined, there was nectar present, though it was meager in quantity. Whether it varies in abundance in different varieties I am unable to say, but probably there is not much difference.

Not once during the entire summer did I see a honeybee on the flowers, though they were flying across the garden by the hundred. Evidently they can not obtain the nectar. One day I saw them alight on the leaves for the purpose of obtaining water, which was still remaining there from a previous rain. Several times I saw a queen of *Bombus fervidus* visit the flowers in the legitimate way; but, as in each instance, she visited only three or four flowers, I concluded she found very little nectar. I have never once seen the honeybee obtain the nectar of the garden pea; and, so far as I can learn, in not a single instance is there an authentic record, either in Europe or America, of any one ever having seen honeybees actually sucking the nectar of the edible garden pea.

The garden pea as a honey-plant is, then, of no value. Almost invariably they are self-fertilized. It was, indeed, for this reason that Gregor Mendel selected them for his celebrated experiments in hybridization. He crossed a tall variety with a dwarf, and all the offspring of the first generation were tall. A cross between round peas and wrinkled peas gave in the first generation hybrids which produced only round peas; while a cross between white and colored flowers yielded hybrids with colored flowers alone. As he raised a great

number of plants which grew outdoors, his experiments would have been impossible had the flowers been frequently pollinated by insects. In his famous paper, which is now before me, he says that the risk of false impregnation is very slight. "Among more than 10,000 plants which were carefully examined, there were only a very few cases where an indubitable false impregnation had occurred."

Here are two kinds of flowers belonging to the same family, possessing form, structure, color, odor, and nectar, adaptations for insect pollination, and yet they are rarely visited by insects. It would be easy to draw hasty conclusions. But let us remember that these plants are growing far from their original home or habitat under greatly changed conditions. The sweet pea comes from Sicily. The garden pea is no longer known in the wild state, but is believed to have been introduced into Europe from Western Asia. It was cultivated by the ancient Greeks, and even in the prehistoric times of the bronze age, for the seeds have been found among the relics of the lake-dwellers of Switzerland. Though only occasionally cross-pollinated to-day, there is not a shadow of doubt that insects have played a most important part in the past history of these flowers, when, growing wild in some distant land, they were in the process of becoming what they are. Their utility to man and their existence in America depends upon the fact that they have retained the power of self-fertilization.

Though acclimatized strains of the sweet pea are fruitful in India, seed brought from and sown in the gardens of Calcutta produces plants with small leaves and a few sterile flowers. How mistaken would be the conclusion of a native of India who should form the opinion that the flowers are *never fruitful*! We who live in America would err to an equal extent if we should assert that insects had never been beneficial to the flowers of the garden pea (*Pisum sativum* L.), or to those of the sweet pea (*Lathyrus odoratus* L.).

Waldoboro, Maine.

BEES IN AN ATTIC IN A CITY OF 423,000 INHABITANTS

BY JOHN A. BRAME

In the spring of 1911 I purchased a colony of very gentle yellow bees for \$10.00, giving the price for the bees only, as I furnished my own hive, of which I had plenty. I had lost five colonies the previous fall because sickness had prevented my giving them the proper care.

Placing this hive in the center window of my attic was an experiment which, so far, is a success. This colony gave me 64 sections of clover honey during 1911, and cast a swarm late in August, which was prevented from leaving by a trap at the entrance for catching the queen.

The year 1912 was a banner one for me. The daughter of the original colony gave me 96 sections of clover honey.

Hive No. 2, which had contained the old queen, was queenless early in the spring; so I lost out there, as I did not discover it soon enough to get any surplus.

Hive No. 3 is a collection of swarms, or, rather, part of two swarms of which I could not get the queens. Part of one swarm is from a church chimney; the other is from a 40-foot pear tree. A friend in Beeville, Texas, in the bee and honey business, promised to mail me a queen. As luck happened, the queen came the day I captured part of the pear-tree swarm. I locked the bees in an observation hive for three days, with this queen caged, after which she began to lay. A few days later I got part of the chimney swarm. These I kept in a paste-board box in the cellar for three days, feeding them through a screen top; then I punctured a hole in the box and set it under the observation hive which they also made their home.

Previous to purchasing this \$10.00 colony I kept bees in my back yard; but I had a neighbor who thought more of cleanliness than godliness, and had the habit of beating rugs and carpets practically all day. Since I have had them in the attic the regular spring and fall carpet beating is sufficient. Being confined all day in the dust and dye-laden department store I find it a relief to work with my bees in the evenings and holidays. The \$10.00, I figure, was well spent; and if I ever want another colony I shall not hesitate to pay the same for it.

Buffalo, N. Y.

A Correction

In regard to the illustration, page 350, May 15, there was a slight error made in reproducing my sketch. The super should be shown with the end toward the reader, not the side. The great advantage in using such a device is the ease and quickness with which a super can be set on it without crushing bees, and with the knowledge that it will stay where you put it. The cover need not be removed from the super—just raise the super with the cover; puff in the smoke and lift the super on to the holder. I prefer the box arrangement, as it is handy for fuel for the smoker, bee-brush, and tools that are apt to be mislaid and must be hunted for when wanted.

Mystic, Ct., June 4.

ELMER E. WAITE.

Heads of Grain from Different Fields

A Peculiar Malady or Disease

Having a colony of bees whose case I do not understand, and can find nothing in my books and papers to explain, I take the liberty of writing you if, perchance, you may be able to give me help from your experience and knowledge of the experience of others.

During the day all seems to go well; but at night I notice a peculiar odor at the entrance, not unlike the odor of a colony when stirred up and angry, but stronger. It was a sort of combined odor of acid and bitter; and in the morning, before sunrise, I find a lot of bees in front of the hive apparently dead, though they nearly all revive when the sun warms them up. Indeed, they keep crawling out one or two at a time until the sun shines quite warmly. They come out with tongue extended and dragging, and keep clawing at the tongue, and, indeed, somewhat at head and antennæ with the fore feet, as though something tasted very bad. In a few minutes they cease to struggle, and lie on the alighting-board apparently dead until thoroughly warmed up, when many of them revive and fly away, though some die. When the warmth begins to revive them they first begin to move the legs; then the abdomen begins to move with respiration, and after a time they begin to buzz and tumble about in a drunken sort of way, and at last get on the wing and disappear. Most of those that do not recover revive somewhat, and crawl about for a time, but do not establish abdominal respiration, and finally give up.

There seems to be no noticeable alteration in shape, color, or condition, except the extension of the tongue, and perhaps drooping of the head, the most noticeable thing being the clawing at the mouth and especially the tongue.

I have noticed a few carrying in pollen of a deep purple color, and picked up one sick bee carrying a full load of it. The colony cast a strong swarm in May, and the hive is now well filled with bees. The queen seems to be laying now very nicely, as they have some brood in various stages, though I was not able to discover any until the last few days after I had given them a frame of brood, fearing their queen was lost. They have quite a quantity of newly stored unsealed honey, and are carrying lots of pollen every morning, and keep busily at work all day except that to-day they spent an hour or so buzzing about the entrance and vicinity of the hive, much as young bees do at first, though I am sure none have yet hatched from the young queen's eggs, and all the brood left by the old queen hatched, and the cells were all cleaned out long ago.

S. FRED WEBBER.

Colorado Springs, Colo., June 24.

[We have carefully read all you have to say, but are unable to decide what is the real cause. There are some symptoms that seem to indicate bee-paralysis. Other symptoms seem to point to poisoning. We can not understand, though, why the bees should apparently revive if poisoning is the source of trouble, when they begin to warm up in the morning. If any of our readers can offer a satisfactory explanation we should be glad to hear from them.—Ed.]

Freaks of Swarming

I should like to know if others have had the same experience with bees that I had this morning. My hives are marked A, B, C, etc. I saw that the bees were clustered on A and C. I went up to them, and a swarm came out of C and soon pitched on an apple-tree. As soon as they were settled I got things ready and shook them. They went into the hive all right; went back to the other hives and found the bees coming out of A with a rush. They whirled around in the air, and I waited for them to cluster,

but they did not, and soon I saw that they were going into C, where the swarm had just come out. There was no fighting nor disputing about it. I thought it was the same swarm that issued; but it was not. That swarm is in the hive they went into. The bees that were clustered on the alighting-board of A did not fly; and after the rush was over they went into the hive. They are flying at 2 P. M., while those in C act quite like a new swarm getting settled in new quarters.

Norridgewood, Me., June 27. MRS. ROSA WADE.

[Sometimes during the swarming season bees will act as if they were crazy. Instead of behaving themselves as bees should, or as laid down in the standard text-books, they will go contrary to all rules of procedure in the case of swarming, and leave their owner guessing just as they have done with you. There was nothing unusual in the case of the first swarm that came out and which you hived; but it was quite unusual for the other swarm to go out and to go into the hive where the first swarm came out. We don't know how to explain it other than to say it was a freak swarm. We should naturally expect that the swarm that went into C would come out again, because the cells left in C by the first swarm will soon start an after-swarm, providing the honey-flow continues.—Ed.]

How to Protect Combs from the Bee-moth

Please tell me how to keep combs of honey, and where to keep them to keep the moth from getting to them, and how to keep extracted combs. I should like to save some over for another year if I can do so. The moths are plentiful here.

REV. F. M. WELBORN.

Newcastle, N. C., June 24.

[Combs of honey or empty combs left on hives containing Italian bees or their crosses will be comparatively free from the wax-worm. After combs are removed from the hives they should be placed in a building that is bee-tight—that is, a building where neither the moth-miller nor any bees can get at them. If so protected there will be no eggs laid, and consequently no work of the wax-moth. If, however, the combs contain eggs from the wax-moth before they were put into a tight compartment, the wax-worms will develop later on. Where there is any trouble of this kind it is usually the rule to stack the combs in a series four or five high, place a saucer of carbon bisulphide on top of the combs, then cover the whole. The fumes of this stuff will settle down and destroy the eggs or any moth-millers that may be present. Sulphur may be used in a similar way. But, as a rule, apply the brimstone or sulphur in a room. Place a quantity of it in an iron kettle and ignite it. The room is then closed, and left for twenty-four hours. For full particulars on how to take care of such combs see "Bee-moths" in our A B C and X Y Z of Bee Culture.—Ed.]

"Honey-bound" Queens

In looking over the colonies this morning I find two without brood, one with only a little. One has the brood-chamber full of honey, but is beginning to work in the super, so I think they may take that up into the super. Had I better put a new queen into the two that show no brood? I could not find a queen in either colony, but they are working—one of them very well, the other not so well.

Lakewood, O., March 3. J. D. McCALMONT.

[It is not entirely clear to us whether the two colonies you mention are queenless or not. When there has been a heavy flow of honey a colony will get into a condition that we call "honey-bound," that is to say, every available cell is filled with

honey, so that the queen is crowded out absolutely. In that case she will shrink down so that she will not look much larger than an ordinary bee; but, as a general rule, when a hive is honey-bound there will be a few eggs and young brood which the queen will somehow manage to find room for. Taking every thing into consideration we are inclined to the opinion that the two colonies mentioned are queenless. To prove this, give them a frame of unsealed young brood. If cells are started, of course you will know that they are without a queen. If you wish to save time it would pay you to put a laying queen in each of the two colonies if they are queenless. If you would like the fun of raising queens you can raise your own.—Ed.]

Another Plan of Increase

I have been trying a new plan for artificial swarming which seems to prove a good one. The plan is as follows: Take a hive (one-story); fill it with brood-frames, and place it on a strong colony. The bees will soon begin to work in the frames, which should be above the old brood-nest, and the queen will begin to lay in it. When the brood is in all stages, smoke the bees at the entrance of the hive, then carefully take the new brood-nest and carry it to the new hive or place where you wish it to remain. In this way it leaves both hives strong. Care should be taken, however, or you will receive a severe stinging.

Waverly, N. Y., June 26. J. M. ELSBREE.

[The plan will work in most cases during warm or hot weather; but in early summer or spring there will be danger that some of the brood will be chilled or neglected on account of old flying bees going back to the old stand. The Alexander plan removes this difficulty, and in most instances the beginner will succeed better.—Ed.]

Small Queens; Variation in Markings

Would you please answer the following questions for me?

1. Do hybrids fly as far as the Italians do?
2. Did you ever know of a queen no larger than a worker bee? In clipping the wings of my queens I came to one hive where I could find none, but found unsealed queen-cells and also numerous worker eggs regularly deposited in worker-cells. They had not cast any swarm yet. The next day they swarmed; but the swarm returned after clustering in a tree-top. I found the queen in front of the hive as her wings were a little ragged, so she could not fly well; but she was the real queen, as I caged her and the bees would cling to the cage very persistently. Why do you suppose she was so unusually small? Do you think she would be as good as a normal-sized queen? She had a very populous hive.

3. Have not queens which produce a few black drones and workers been mated to a black drone of the ordinary common black or German bees?

Swea City, Iowa, June 30. ALBERT SWANSON.

[1. Hybrids fly as far as Italians. There is no reason why they should not.

2. Occasionally we find a queen not much bigger than a worker bee. They usually are not of much value, and are supposed to have been raised from a cell where the larva was too far developed. Such queens should be replaced. It is evident from the general description in your letter that she was not doing very well, because the bees were building cells and trying to replace her. There is a possibility, also, that the bee that you found was nothing more nor less than a laying worker. There will be several of them in the hive; but from your general description we should be inclined to believe that what you found was really a queen-bee but a very small one. It is proper to state in this connection that, after a queen has ceased laying in the fall of the year, she will shrink down so that she will be only slightly larger than a worker-bee; but in this particular case

it is evident that the queen was at her best, which was very poor.

3. Yes, a queen which has mated with a black drone will produce bees and drones of various markings. Sometimes the hybrids are uniformly marked as two-banded bees; but as a rule there will be three-banded bees, two-banded, one-banded, and black bees in a cross of this kind.—Ed.]

Is it a Disease or Something they Gather?

I notice in GLEANINGS, June 1, page 387, that Mr. B. L. Fisher tells us that his bees are troubled with paralysis. I was much interested in the article, because in some respects my bees are in a similar condition. I have worked considerably with professional beekeepers, but this is the first season I have had bees of my own. I have had ample opportunity to watch and study the actions of my bees, and feel inclined to believe that, at least in my case, it is not paralysis. While I have been watching, a bee from the field would alight in front of the hive, a guard would grab it by a leg or wing, and the guard would not attempt to sting the victim for quite a while. Then it seems as if the guard stings the other in the abdomen. The one that has been stung just hops about on the ground, not able to take flight again. Sometimes the would-be victim breaks away from the other and goes into the hive, and no other bees interfere with it. All my stands have plenty of honey; no robbing going on. All stands have the same trouble. It seems that there are no bees being killed inside the hives because there are none being carried out. It appears to me that the field bee loses its exact colony odor, or the guard mistakes its own colony odor. There are a great many acres of Himalaya blackberries that have been in bloom for two weeks, which has been the main source of honey and pollen. The blossoms are very fuzzy, and the bees wallow among the hairy stuff, one after the other; therefore I thought some of the bees might have taken up some of the odor of other colonies. I did not experience any of this trouble among the bees until the berries came in bloom. It keeps my colonies about at a standstill. I hope that some of the experienced beekeepers will give more light on the subject.

Watsonville, Cal., June 24. C. W. ARNETT.

[The fact that you say the trouble began after the bees began to work on the Himalaya blackberry rather suggests that this plant may be indirectly the cause. It is possible that some hairy substance, or the pollen itself, perhaps, besmeares the bees in such a way as to make them unwelcome to their former comrades. If any of our subscribers have had a similar experience we should be glad to hear from them.—Ed.]

Propolis on Hoffman Frames

I am using Madary's ten-frame hive, which is 16 inches wide, and I find that, after the Hoffman frames have been handled a few times, enough propolis gets stuck in between them to make it impractical to use the full ten frames. I have been asking several beekeepers how it would do to use nine frames and a follower; but they all say that a follower is a bad thing, as it gets stuck in the hive by brace-combs. What would you do under the circumstances?

Modesto, Cal., Feb. 5.

SUBSCRIBER.

[The use of a follower is largely a matter of personal opinion. Some beekeepers will not use them—can not be hired to use them—while others prefer them every time. It is true that it is often difficult to get a follower out without breaking it. Possibly those who will not use a follower could be induced to do so if the construction were much more substantial than it is now.

Under the circumstances, since your hives are not quite wide enough for the ten frames we would certainly use nine and a follower.—Ed.]

Our Homes

A. I. Root

In his law doth he meditate day and night.—
PSALM 1:2.

I have made another "discovery," and I rather think it is a *great* discovery. Suppose you try it and see. First let me say that it seems to me that the older I grow the busier I become—that is, there are more things I want to do than I can get around to. There are more of God's gifts I wish to "investigate;" and for years past I have been feeling that I could not waste a minute of time. Mrs. Root often asks me to go visiting among the neighbors. Well, if said neighbors are like myself, and are exploring God's gifts in the way of bees or chickens or the garden, I am glad to visit them; but I do not want to sit down on the porch and talk about this, that, and the other. I want to be *doing* something.

My good friend Prof. Holden, in one of his "corn talks," spoke of pulling up some of the stalks that did not have any ears, and using them for fodder, giving the rest a better chance. He said a boy in his audience once suggested that these drones among the corn were just standing around all summer long, "doin' nothin'." Now, there are people in this world—yes, a good lot of them, standing around with their hands in their pockets during this beautiful month of June doing nothing, like the useless cornstalks. I could not stand that way of living. It would kill me. I have to be busy. I want my life to produce *ears of corn* or something equivalent, that is good for humanity. When it ceases doing that I hope the great Father will "pull me up" so as to give "others a better chance." Now for my discovery.

For fully forty years I have objected to being obliged to sit still and do nothing. Yes, before I was among the church people I objected to seeing great audiences sitting still until services begin—that is, if they happen to come early. I used to tell Mrs. Root I did not want to go to church until things got under way; but she very much objects to being late at any public meeting; and as each one of us stuck to our respective point there did not seem to be any "common ground" other than being right on the mark when meeting opened; and of late we have tried to come to an agreement that way. An electric automobile is a wonderful help in that respect. I can read my *Sunday School Times* until within three minutes of church time; and even if our bungalow is a little more than half a mile from the church we can be there promptly—that is, with the aid of the electric auto.

I have been calling this beautiful "spry" little auto one of God's gifts; but some of you may insist that this is a gift from the ingenious brain and skill of mankind. Well, you can have it that way if you choose, for God gave the wonderful brain and astonishing skill of our best mechanics of this present age. Do you ask why I do not put the *Sunday School Times* in my pocket and read it after I get to church, provided I get there before services are started? Well, I have done that, both in Florida and Medina. It has always been a question in my mind whether one ought to be seen reading a paper or, say, a letter while in church. It is not exactly common, and I am not sure that it ought to be. If everybody knew I was reading the *Sunday School Times* instead of a daily paper (or a Sunday-morning paper), it might be better. Keep in mind that I am always in front as close to the good minister as I can get, principally on account of my deafness, but also because I have all my life wanted to get up in close touch with the teacher, preacher, or the boss; and I am sure I have been benefited by so doing. I have no patience with people who crowd in on the back seats as far from the speaker as they can get. Our own pastor has urged and exhorted people to come up and fill the front seats first, and leave the back seats for the timid ones or strangers; but not half a dozen people, unless they were deaf like myself, heeded the pastor's request. Mrs. Root would come up well to the front were it not that she is a fresh-air advocate. Sometimes I am inclined to call her a fresh-air *fiend*; but the word "fiend" does not fit her in any respect whatever. I might call her a fresh-air angel, but she would object to that title as much as to the other.

Well, now we are getting close to my discovery. My conscience has always troubled me when I sat up in front reading the *Sunday School Times* or even that bright little Sunday-school paper we have down in Florida at our Presbyterian Sunday-school called *Forward*. I have for years past carried a good-sized Bible, with coarse print, that I can read easily. Bro. Rood, the superintendent of our Florida Sunday-school, asks every morning, "How many of you have brought a Bible?" Well, I have always felt ashamed when I have had no Bible to hold up. One Sunday I picked up an old rusty Bible that I found on the seats, and asked him if that would not do. He shook his head while the audience smiled. He said he wanted everybody to bring his own copy

of the Bible. I tried to excuse myself one Sunday morning by saying, "Mrs. Root forgot to bring ours." But the superintendent would not accept that as a good excuse; and when I was obliged to see there was no other way I carried my own Bible every time.

Well, my good pastor of the Congregational Church here in Medina is following Bro. Rood. May be, however, he is ahead of him. As soon as he came to Medina he commenced building up our prayer-meeting—yes, "building up" is the word; and just as soon as the meeting was opened on Thursday night he would say, just as Bro. Rood does, "How many of you have your Bibles in hand? Hold them up."

Now, although it is not a part of the discovery I am going to relate, I want to say right here that our Medina prayer-meeting has been built up from a dozen or so (perhaps more in good weather) to over 100. We recently had 127 out to our week-day prayer-meeting. Yes, they were "mostly women," as you may guess; but may God be praised for the women. They are going to vote pretty soon here in Ohio, and then you will see whether or not they will "count," and count for righteousness.

Well, since I have opened the way pretty thoroughly, as you will probably all agree, I now want to announce my discovery. Nobody thinks of objecting—surely not the pastor of the church—if you open the Bible you have been carrying under your arm and read it at every opportunity when one minute seems going to waste. If I get there early I read my Bible; and while they are singing—at least while the choir is singing*—I read my Bible. And while they are taking up the collection I read my Bible. I began with Genesis and have read it to myself in church, clear up into Exodus. During our Sunday-school lessons in Genesis I read many parts of that book over and over; and it has not only been a great help but a great blessing as well. Of course, I do not think of reading even the Bible when our pastor is speaking or when they are singing, and the audience is expected

to join in. I try not to be so rude as to read while anybody is talking—that is, when he is talking about any thing I am expected to hear.

Now, if you want to test my discovery and decide for yourself whether it is a great discovery or not, take your Bible—the one you are used to and are familiar with, to Sunday-school, prayer-meeting, Christian Endeavor meeting, to the Y. M. C. A., or to the Men's Brotherhood. When the Bible or something from the Bible is touched on, you want to be able to put your finger on it quick. I am getting to be quite an expert, if you will excuse so much boasting, in turning to any passage quickly that may be inquired about or called for; and you do not know how happy I feel over it. Now ask your pastor and Sunday-school superintendent or any other good authority if anybody can think of objecting to your having a Bible with you, especially on Sunday, and reading it at every spare moment. Does God's word indorse my discovery in that beautiful first Psalm—"in his law doth he meditate day and night"? Of course, all people do not look at the Bible and regard it as I do; but I think I may safely say that it does not make any difference who you are or what you believe, it will richly repay you to become conversant with that book. If you are a skeptic or an infidel, and will continue to read the Bible as I have been reading it year in and year out, it will do you a vast lot of good. I think I may safely say it will be money in your pocket, although I dislike to speak of the Scriptures in that way. Let me tell you a little story I have told before. It fits in exceedingly well right here.

My good friend Irving Keek, who occasionally writes for these pages, was a well-to-do banker, and started off with his wife and family to locate in Southern Florida. In order to reach their destination they were obliged to take a long drive through a large piece of woods, without any human habitations on the way. Their route took them over a road that had been very much injured by floods. When out in the woods, miles from any dwelling, their wagon was overturned; and while the good wife was not much injured, their year-old baby was killed. There was no other way than to bury the little darling of the household in that lonely spot—at least for the time being. The mother was a professing Christian, but the father was not. At that date (years ago), it was not customary or "fashionable" for bankers to be professing Christians. I wonder if there has not been a change for the better since that time. Well, before that sad household had fixed up to

* Years ago, even before I was a Christian, I made the discovery that I could enjoy a good book or a good story, for that matter, very much better when listening to music. When my two sisters were playing together on what we called a melodeon in those days I would many times get a favorite book and get enthusiasm and inspiration from the book and music together; and throughout all my life, if I want to enjoy looking at a beautiful picture or painting, or even a piece of statuary, I sometimes have a craving for music for an accompaniment. Now, then, while the choir were singing some beautiful anthem I would turn over and read the story of Joseph; and with the inspiration of the music, and, I may say also, with the sense of the presence of the Holy Spirit, I could comprehend God's dealings with mankind in a way that would be almost impossible without the stimulus of inspiring music.

go on their lonely drive, Mrs. Keek insisted on some sort of funeral service over that little new-made grave, and they read something from the Bible, or friend Keek did, and then during those brief sad rites she asked Mr. Keek to give her his promise that he would read at least a little something out of that Bible, God's holy word, every day, for one year, in memory of the death of the little one so suddenly snatched away. What father, under such circumstances, could refuse such a request? Of course he gave his promise; and being a banker, and a successful one, he kept his promise sacredly. What do you suppose was the outcome? I hardly need tell you. Before a year was up, perhaps long before—I can not quite remember—that daily Bible-reading made him a humble follower

of the Lamb of God who taketh away the sin of the world; and he has ever since been not only a professing Christian but a working one. So much for keeping a promise to read the Bible every day. This was long before, mind you, the Endeavor Society was established with its "iron-clad" rules including the one commencing, "I promise to read my Bible every day."

Now, friends, how many are there who will give me a like promise to read the Bible every day—that is, where and when circumstances will permit? And if you will give me that promise and send it to me on a postal card, I am sure you will find the other part of that second verse of the first Psalm is also true—"But his delight is in the law of the Lord."

High-pressure Gardening

FLORIDA AND OHIO CONTRASTED.

One reason why I like to make garden in Florida is because the soil moves so easily, or at least in the greater part of Florida. It is a sort of sand or light sandy loam; and even if you are old and feeble, you can, with a very light hoe, move the soil and do a lot of work without very much fatiguing exertion. And it is the same way in spading up the ground. If you do not want to bother with a horse, by taking it easy you can take out great shovelfuls; and if there is any trash on top you can turn it under. Now, after working in that sort of soil all winter it is something of a jar on one's nerves to attempt to make garden here in this stiff yellow clay of Medina Co., Ohio—at least the greater part of this county is that way. After the great floods, of course the ground had settled down hard and was uninviting to look at. Although there is an abundance of underdrains under my quarter-acre, the ground was about as hard as a brickyard. We covered it pretty well with manure and waited for it to dry off. But the young people got in such a hurry to have their garden plowed that they could not wait to have theirs dry, and I reluctantly permitted our teamster to plow my garden also. Had it been ridged up in the fall with good deep ditches between the ridges, so the frost could work it up, it would have been very much better; but this was neglected. We had it plowed and harrowed, and worked with a disk as well as we could. And then we planted our potatoes, corn, beans, etc.; and as the weather grew warmer (or at least it ought to have been warmer), we put in our lima beans,

Hubbard squashes, melons, etc. Well, here in Ohio we had, first, a remarkably cold wet May. Finally the rains let up, but it was so cold that we had a little touch of frost on the 8th and 9th of June. Then it stopped raining for about a month. Most of the potatoes came up; but the first planting of corn, even the Golden Bantam, only about a half of it came up. In order to get a stand of corn where it failed on account of the cold and wet, we planted it over *four times* in all; and then when we found a hill was an entire failure we put in string beans. Of course I am speaking of sweet corn. The Golden Bantam stood it the best of any; but the regular sweet corn, or the biggest part of it, could not stand the cold clods, for our whole garden (until almost the first of July) was little but clods, thus presenting a great contrast to our Florida soil.

Oh! I forgot to say there are no gravel stones in Florida. In digging ditches or making garden one never finds a pebble of any size. That is one reason why we have to purchase grit for chickens. There are no gravel stones—at least not in our locality.

THE DASHEEN IN OHIO.

I brought with me from Florida, about the middle of April, fifty or sixty dasheen bulbs. Then I got a big sheet-iron wheelbarrow, almost as soon as I arrived here, and filled it with rich garden soil and old manure, about half and half. As it was too cool to put these tropical tubers in the ground I planted them in that wheelbarrow. I wheeled them out when the sun shone, and wheeled them back in the basement at

night! and to boost them along I put them near the gas-burner that burns all night to give hot water as well as cold. They had begun to sprout when I left Florida; but they did not seem to take kindly to the existing conditions here in Ohio. When I planted them out in the open ground along in May I felt a good deal discouraged. Only two or three had begun to grow and put out their white rootlets. However, I stirred the ground around them, and a few of them ventured to peep out through the soil; but I had to cover these few to save them from the frost. It was along the first week in June before I began to have any hope of my dasheens. When I saw, however, that about half of the number* had begun to start I dug away the soil around the whole of them clear down so I could see the little white roots. Then I put around in this cavity a mulching of old well-rotted manure and covered it with soil. When the warm weather came on the last of June they began to send out rootlets into that rich compost; and whenever we had a warm spell they began to grow. But the dry spell came on, and that did not suit, because they are what I might call half aquatic in their habits. I got out my garden hose and gave them a thorough soaking. But the fierce hot sun was up to 100 degrees the last of June, and this great heat baked the soil and made the leaves curl up. That did not suit me. I told our teamster to get me a big load of well-rotted manure and haul it up near the dasheens. Then I mellowed up the soil and mulched the whole surface of the ground and around and between the dasheens. Then I gave the whole batch a thorough soaking with the garden hose. I made it wet clear down, and kept wetting it every other night just about sundown. Then I began to get my reward. That suited the dasheens to a dot; and, by the way, it also suited the rows of corn and potatoes on either side, because I kept stirring up the clay soil with the chunks of manure. The lumps that were left in plowing began to slacken up; and to-day, July 9, I have a nice mellow soil that works about as easily as the Florida sand. Not only are the

dasheens booming, but the rows of corn and potatoes on each side of the dasheens have got track of the rich food, and are sending their roots over into that manure compost. To see how fast the corn grew I stretched up a leaf one morning, and found that it reached to my hip pocket, and it kept growing about two inches a day until we had a big thunder-shower, or a succession of them; and when I could get out to measure my corn leaf it was higher than my head; and what a beautiful dark green those hills of sweet corn did put on! And the rows of potatoes on the other side that had, during drouth, almost given up, just put on "new life."

Now, if you wish to know what I am driving at, it is this. You can do high-pressure gardening if you are willing to work, in the most forbidding soil, and no matter whether it rains or not, if you have arrangements to furnish good old stable manure and plenty of water. With all the discouragements and stumbling-blocks we have had this queer season, we have about the finest garden—at least where I applied the water—I ever had. As there was some manure left after treating the dasheens I gave some to some cantaloupe melons and Hubbard squashes. The way I did it was to take away the soil clear down until I exposed the tender white roots. Then I filled this cavity with old black manure and covered it with fine soil, first soaking the manure thoroughly with water, pouring on water several times until the dry thirsty earth was saturated. The Hubbard squashes got over their discouraged look, and "sat up nights" to put out big leaves and send out big runners. A drenching thunder-shower is rather better with its moist atmosphere than artificial watering; but the water is very important when we have a long dry spell.

Some of you may suggest that it does not pay to go to all this fuss for a little garden spot—better buy your green stuff at the grocery. But I tell you, friends, it pays in two ways. First, you have fresh vegetables, better than can be bought anywhere—at least as a rule. Second, and most important, you have the satisfaction of demonstrating that you are boss of the elements. In other words, you can get a crop in spite of frost, drouth, too much wet, or any of these hindrances. It hurts me mentally, physically, and spiritually to undertake a job and make a failure of it. So far as I know I have the first dasheens planted in Ohio; and if I succeed in demonstrating that these delicious vegetables can be grown here as well as in Florida I shall have ac-

* I am glad to tell you that every single one of the dasheen tubers came up sooner or later; and in some hills where they were so badly dried and wilted that I put in two, thinking that possibly one might live, both came up. Now, here is another matter: In several places I carefully dug out one of the tubers and transplanted it. Of course they had quite a few of these young white roots and rootlets; and every one grew, and I think I may safely say it is a very easy vegetable to transplant. This is a matter of considerable moment, for probably the only way to raise them here in the North—that is, to get a good crop—is to start them in a greenhouse; then after they have some little leaves and a lot of rootlets, put them out as you do cabbage, tomatoes, etc.

complied something that can scarcely be computed in dollars and cents.

There is one thing I almost forgot in contrasting Ohio with Florida. The stable manure that I have been describing costs here 75 cents a load. In Florida it is \$3.00, and I doubt if you can get any old manure there, such as I have described, at any price. It is all taken up from the livery stable about as fast as it is made. Another thing, this heavy application of manure here in our soil will benefit that piece of ground for several years. Down in Florida the tremendous rainfalls (one inch a day is reported just now) take the strength from the manure by leaching it so that it is good for vegetation for only one season, or the greater part of it. Most people are greatly disappointed when they undertake to make garden in Florida because of the absolute need for a constant and repeated supply of fertilizer of some kind. Coarse stable manure furnishes humus that holds the water; and this is very important both in Florida and Ohio. Old worn-out farms are usually worn out because the humus has been exhausted by repeated cropping, and no putting back.

MORE ABOUT THE DASHEEN, "THE TUBER THAT MADE BROOKSVILLE FAMOUS."

We clip the following from the *Florida Grower*:

But it is not of the beauties of the hammock nor the rolling lands nor the view from the court-house over the surrounding country, worthy of an artist's brush, that Brooksville's fame rests, but upon the dasheen. It's "The tuber that made Brooksville famous," for here it grows to perfection. They cultivate it, cook it, eat it, talk it, and dream of the dasheen. You can't be in Brooksville five minutes and commence to remark upon its beauties and possibilities without some one asking, "Have you ever eaten a dasheen?" And you will be told that your education has been neglected if you have not tasted of this delicacy.

Dasheens do not do well on dry sandy soils, needing a moist soil thoroughly drained, though they can stand flooding once in a while, and seem to do better where this is resorted to occasionally. A low moist sandy soil, well fertilized, capable of irrigation, will produce dasheens; but the yield will be less than that on the hammocks with a clay or limestone subsoil. It is related to the well-known elephant ear (*Caladium*), so common in all our gardens, and any soil that will grow elephant-ears well will do the same for the dasheen.

A few days ago, while our teamster was cultivating the garden, he came up alongside of my two rows of dasheens and stopped his team and looked at me in a sort of puzzled way and remarked, "Why, Mr. Root, what in the world are you doing with those 'splatter docks' growing here in your garden?"

In the fresh-water lakes along close to the shore there are frequently found patches of what we call water-lilies; but the com-

mon people, especially the fishermen, have been in the habit of calling them "splatter docks;" and I remember now that they used to bother us a good many times in trying to get our boats through them. The finest black bass are found hiding along these splatter docks. I have scarcely seen them since my boyhood days, but I remember them as a rank luxuriant vegetation; and when they obstructed the passage of the boat there were often a good many complaints of "them pesky splatter docks." And as these dasheens, when about a foot high, do look very much like splatter docks, it occurs that, like the "elephant-ears," they need lots of water. Mine are doing very much better since I gave them water as well as lots of old well-rotted manure unstintedly. I expect to give soon a picture of them as they grow here in Ohio.

DASHEEN BULBS FOR PLANTING.

When I saw Crenshaw Brother's advertisement of dasheens for planting I wrote them, asking them how they succeeded in keeping the bulbs, say during the summer months. Their reply would indicate that the bulbs can be kept for planting at different seasons of the year very much as we keep Irish potatoes; and this is certainly another thing in their favor. See the following:

Your inquiry in regard to keeping dasheens is at hand. We would say that we have a few bushels that are sound, and are in first-class condition. These bulbs were gathered last fall. We have met with excellent results in keeping these, also small seed Irish potatoes, by making frames with the bottoms out of slats, spacing them by stacking them on top of one another, which leaves plenty of room for the air to circulate. About once a month we have a man to go through them to see if any are faulty. We find that they can be kept at very small expense.

CRENSHAW BROS. SEED CO..

Tampa, Fla., July 11.

Later.—Dr. E. F. Phillips, Apicultural Expert in the Bureau of Entomology, Washington, D. C., has just been looking over the dasheens in our garden, and he remarked that on a recent visit to Porto Rico he found they were there a staple article of food, and he himself is very fond of them. He gave me one important pointer right here. He says they are grown largely on the margin of running water. On each side of a little rivulet, so close to the water that the roots of the dasheen can get right over into it, the rankest specimens are growing. I believe it is known in Hawaii by the name of "taro." Now, in our effort to reproduce it here in our own country, let us remember it needs lots of water.

Dr. Phillips says this vegetable was the principal article of food of the natives before the missionaries commenced their work in the Sandwich Islands, as it was then call-

ed; and he says that, furthermore, even now a large part of the inhabitants, especially the natives, make the dasheen their principal article of food.

On a recent visit to the Philippine Islands he found there also the dasheen or something similar to it, and it was there considered an important article of food.

THE DASHEENS DOWN IN FLORIDA AT THE MIDDLE OF JULY.

My colored man, who is looking after them, writes me as follows:

The dasheens are getting along finely. The younger ones are larger than the older ones. They are a pretty sight to behold.

Manatee, Fla., July 12.

WESLEY WELCH.

Temperance

"WHAT SHALL THE HARVEST BE?"

Whoso shall offend one of these little ones which believe in me, it were better for him that a millstone were hanged about his neck, and that he were drowned in the depth of the sea.—MATT. 18:6.

On page 360, May 15, you may remember that one of the friends replied to a question of mine as follows: "No, I do not keep bees. I keep *busy*." I there explained that the above was from L. H. Horton, of Spokane, Washington. It now transpires that friend H. is District Superintendent of the Antisaloon League of Washington, and a pusher; and I am going to tell you *how* he "pushes" things, by giving you three pictures and the printed matter that goes over and under these pictures. Here they are.

Let us look into this matter a little. The picture of that bright boy might be that of your boy or mine. There are thousands like him all over the world. He is innocent and unsuspecting. You can see it in his face. Is there any punishment too severe for the man (or woman) who would deliberately plan that boy's ruin? Such a boy is ready to listen to anybody. If his father and mother are not around, it would not be a difficult matter to coax him into almost any thing. He is too young to discriminate. If he were allowed to pass that second picture, the factory(?) (and may God help us in our warfare against such "factories"), his curiosity would be aroused, and, if invited to taste the stuff they have for sale, many such boys would not even hesitate. The proprietors of that kind of factory are just after the nickels and dimes. "Whisky, ten cents a drink!" You need not say this picture was gotten up for effect. It is a photo of what actually exists. Go into almost any big city and see if I am not right. I agree with you that it is a burning shame that such a thing

should exist anywhere on the face of the earth. O God, help us in our conflict against this terrible agency of Satan.

Now, friends, look at the finished product. You know this is true. Probably there are not as many such as there are samples like the boy. One reason is that they fill drunkards' graves before they get to be as old as this poor sot. Now, in view of all this, with these pictures right before you, with the memory of them in your mind, will your conscience permit you to consider for an instant, voting for saloons, breweries, and such things?

Friend Horton informs us that over a million copies of a poster containing these

THE RAW MATERIAL.

pictures have been printed and sent out to date.

AMEN TO THE DECISION OF THE UNITED BRETHREN. ARE THE OTHER DENOMINATIONS READY TO FOLLOW?

Read the following, which we clip from the first page of the *American Issue* for July 5. Is it too strong or too severe? It is taken from the Bishop's quadrennial address at the General Conference of United Brethren, Dayton, Ohio, May, 1913.

A FACTORY.

What would our Town be like if Every Man Drank as much as the Liquor Dealers would like to have Him Drink?

THE FINISHED PRODUCT.

THE CURSE OF CURSES.

We reiterate, with increased emphasis, our relentless opposition to the liquor traffic. We hold that it can not be legalized without sin. Its only argument is an appeal to greed and appetite. It is in collusion with the white-slave traffic and other forms of evil. Its fruits are cruelty, debauchery, conspiracy, and murder. It is the wholesale despoiler of the race, and is "intoxicated with the blood of the multiplied thousands it has slain." As a rising flood it sweeps away life, property, and fortune. It is in a death-struggle for mastery in politics, government, and society. The church of God dare not yield an iota to its murderous march against humanity. It has no rightful place in our modern civilization. It is doomed. The forces that oppose this gigantic evil are in accord as never before. The saloon must be driven out of business. In the name of God, the church, and humanity, let the next final step be a nation-wide movement to outlaw this traffic in a holy crusade for a saloonless nation and liberated humanity under a constitutional amendment of national prohibition.

TRUMBULL CO., O., DRY.

We clip the following from a letter just received from Supt. Wayne B. Wheeler:

Trumbull Co. doubled her dry majority last Saturday. This was done in spite of the fact that more than a thousand voters had come into the county since the last election, and from Warren to Hubbard the valley

is filled with factories, furnaces, and steel mills, which was a tremendous factor.

W. B. WHEELER.

Later.—From the *American Issue* for July 5 I clip the following in regard to the election in Trumbull Co.:

WETS ASKED PERMISSION TO REOPEN SALOONS, AND BY A DRY MAJORITY OF NEARLY TWO THOUSAND THE DRY MAJORITY OF FOUR AND A HALF YEARS AGO DOUBLED.

The wets have had their eyes on Trumbull for some time. The Youngstown and Cleveland brewers have been urging the local booze-boosters to start trouble. They noted Trumbull's prosperity. They saw that in the four and a half years without saloons the county has grown in population and in material wealth. They noted that business is good, that bank deposits have increased, and that men are spending their money on their homes and families instead of piling up the dollars for the brewers and saloon-keepers.

The wets wanted a share of this prosperity. They said to Trumbull County voters: "Here is our proposition: Let us open saloons, and we will trade some of our dirty dollars for your boys and girls. We will give you revenue, and all we ask is the chance at your wage-earners, and at the young fellows who want to put in a crop of wild oats." And back of these Trumbull County wets stood the outside brewers, their greedy fingers twitching at the very thought of getting into the pockets of the men and boys of the county.

"THE FIRST PLACE A POLICEMAN LOOKS FOR CRIME, AND THE LAST PLACE HE WOULD LOOK FOR VIRTUE."

We clip the following from Mr. Bryan's *Commoner*. What do you think of it?

ON THE WALLS OF A SALOON.

A card bearing the following was posted on the walls of saloons in some of the larger towns in Ohio during the late campaign:

"W. J. BRYAN ON THE SALOON."

"From his speech before the general assembly of the Presbyterian church:

"The saloon is a nuisance. The evil can no more be confined to the building in which it exists than the odor of a slaughter house to the block in which it is located.

"I know, and you know, that they are in league with every form of evil in society. As a rule, if you let the liquor-dealer have his way he will have a disorderly house upstairs, he will have a gambling-den in his back room, and his place will be the center of every sort of evil.

"The saloon is the bureau of information for every sort of crime. It is the first place that a policeman looks for crime, and the last place he would go to look for virtue."

THE WOMEN OF FRANCE—A PLEA IN THEIR BEHALF.

Dear Mr. Root:—You are like the Bible—full of contradictions. On page 707 and in Special Notices you say you plead against invectives and for a more Christianlike spirit; but on page 713 you are proud to give print to your grandson's insults against French women. Surely there are awful women in Paris, and there are awful men, too; and there are both kinds in New York also. I guess there are some in Medina too; but this should not allow your grandson to say that French women are awful. If you knew Paris, Mr. Root, you would know that more money is spent there on vice by foreigners than by French people. Cook's Agency pours by the

carload its tourists into the small and dirty theaters of Montmartre; and those rude old maids, respectable matrons, religious and moral English-speaking people, they go there where no decent French woman would show herself, and at the same time help in supporting vice. Please ask your grandson where he has been in Paris.

Is it Christianlike to insult even the poor women who make a living from vice, from men's vice, when the actual society does not permit them to get decent wages by honest work? They have been thrown into that life either by ignorance or necessity, or lack of education, and for their sins why should scores of innocent men, women, and children perish? If your God, Mr. Root, permits it to happen, then your God is not Christianlike, and I am proud to be—

A FRENCH HEATHEN.

I wish you would print my protest in your paper, but I do not expect you to do so.

Palmarito de Cauto, Nov. 9.

My good friend, I thank you for your kind criticism; but I do not agree with your closing remarks, for I am sure you are not "a heathen" in any sense of the word. Perhaps my grandson was a little too sweeping in his statement, as young people are apt to be, and perhaps it is also true that he had not investigated very much in regard to the state of affairs in our great cities here in America. I am sure he did not intend to say that *all* French women are after the fashion of those he happened to get a glimpse of during his brief trip; and I am glad you have called attention to the fact that the bad state of morals is largely due to visitors, many from our own nation. I suppose you are aware that a great reform is now under way in the United States along the line of the white-slave traffic, and I believe this promises to be world-wide.

We are going to print your letter, and it would have been in print earlier but for the fact that it came here during my absence in Florida. May God help us in our efforts to raise up and Christianize abandoned women in every land.

One more word in regard to your concluding sentence. It is true that none of us can fully explain why God in his infinite love and mercy permits many things to happen, as you express it. He permitted Joseph's wicked brothers to cast him into a pit. God permitted them also to sell him into slavery; and in spite of his good behavior and his faith in God, he was permitted to go down into the dungeon just because he held fast to his integrity; and God also permitted him to stay in that dungeon two or more years, while he, poor Joseph, got no glimpse of what was then before him. Is it not possible that God permits the awful liquor-traffic to curse humanity that the good and capable might learn important lessons that could never have been taught them otherwise? Did you ever think of that?

Editorial

THE *Western Beekeeper*, edited by Geo. L. Emerson, has, we believe, come to stay. It is certainly representing the Western producer.

THE MAN WHO INTRODUCED THE FENCE SYSTEM.

ON page 576 of this issue will be found a breezy article by S. A. Niver. He is the man who introduced to the editor the fence system and sections, as used by his brother-in-law, the late Miles Morton, of York State. There is a sparkle of good humor in Mr. Niver's makeup. We are delighted to know that he is now back to his old love, the bees.

THE EDITOR OF THE AMERICAN BEE JOURNAL ON A TRIP THROUGH EUROPE.

MR. C. P. DADANT, of Dadant & Son, editor of the *American Bee Journal*, is now making a tour through Europe to study European beekeeping and the various races of bees. There is, perhaps, no man in the United States who is better qualified to make this kind of investigation. As the French language is his native tongue, and French is universal throughout all Europe, he will be able to make his way everywhere understandingly. The result of his findings will be given later on in the *American Bee Journal*. There is no man better qualified to bridge American and European beekeeping than Mr. Dadant, and our congratulations are extended to our contemporary.

OUR COVER PICTURE.

TAKING the country as a whole, in the localities where sweet clover grows, we think there has never been such a luxuriant growth as there has been this year. The bloom began early, encouraged by frequent rains, and the bees took advantage of it at once. It is probable that there is no great amount of nectar at any one time in the sweet-clover blossoms; for very often, in spite of the abundant growth, the bees do not get very much surplus. In some localities, on the other hand, it yields quite a crop. The chief value of the plant is in supplying enough nectar to keep up brood-

rearing at a time when there is little else the bees can get.

Our cover picture for this issue shows the luxuriant growth of sweet clover along the bank of Rocky River at our "Waterworks" yard, about three miles east of Medina. When all the States become educated to the value of sweet clover, as a few have done, it will no longer be known anywhere as a noxious weed, and beekeepers will reap some of the benefit.

A POST-GRADUATE COURSE IN BEEKEEPING.

J. E. CRANE says, "Inspecting is as good as a post-graduate course in beekeeping," and Crane is right. We have been helping our State Foul-brood Inspector, carrying him about in a machine from place to place. We have learned something about bees and a good deal more about farmer beekeepers that we did not know before. We have seen some of the queer things that bees will do when the owner neglects them and gives them a ramshackled box in place of a good hive. Incidentally we have learned something about human nature, and more about a combination of beekeeping and farming. Sometimes they do not go well together, and at other times they make a splendid combination, providing the women and children take care of the bees while the "man of the house" is in the field. We have run across some delightful farmer beekeepers—some that are clear up to date. They read every thing that is going on with bees; they have all the honey they can eat, and a good deal to sell.

If some of the old-timers think they know it all, let them go out a day or two with their State Inspector, and see if they do not learn something new about bees.

ENORMOUS DEMAND FOR BEES AND QUEENS.

A LARGE number of complaints have come in concerning various queen-breeders, because they have not been able to make prompt delivery on queens. One customer went so far as to say that he wanted Mr. — (one of the most reliable queen-breeders) "shown up." As nearly as we can

ascertain, all queen-breeders in the country have been behind. Some of them are already oversold, and some have declined to take any more orders. The weather this last spring was unfavorable for rearing early queens. It started out in the Northern States unusually favorable. Queen-rearing was nicely started, then there came on a cold spell, chilling the cells and stopping queen-rearing almost entirely.

Another common complaint is that the queens look small and dark on arrival. It is a well-known fact that, when a queen has been deprived of her opportunity to lay eggs, and is shut up in a little cage, and bumped around in the mail-sacks for one or more days, she will shrink up and look very inferior. If a customer will have patience he will find that such queens will, after they get to laying, improve in size and appearance.

INTRODUCING WITH SMOKE; THE PLAN ADVOCATED BY ARTHUR C. MILLER INDORSED BY OUR APIARISTS.

MR. M. T. PRITCHARD, who has charge of our basswood queen-rearing yard, came into our office one day saying he had tried out Miller's smoke method of introducing, and was very much pleased with it. We said to him, "Mell, suppose you write that up." He did so, and here it is:

The article by Arthur C. Miller, on introducing queens, page 370, I consider the most valuable contribution to GLEANINGS that has appeared for many a month. Since reading it I have tried smoking in queens several times under the most difficult conditions for introducing, and found it worked successfully in every instance.

A very strong colony made up entirely of bees that returned after moving several colonies had twice baffled my attempts at introducing a queen by the cage plan. But a queen smoked in at the entrance on Saturday evening was found to have eggs on three frames on the following Tuesday. Had she been successfully introduced by the cage plan she would hardly have been out of the cage by this time. I have introduced into colonies that had been queenless more than 30 days, and in one instance where there were fertile workers. To be able to introduce a queen at any time under any conditions without having to bother with cages and cage candy is an accomplishment worth knowing how.

Medina, Ohio, July 28. M. T. PRITCHARD.

Our Mr. Marchant, who has charge of some 500 colonies in six apiaries, learning of Mr. Pritchard's success, began trying the method. He, likewise, was so well pleased with it that we asked him to tell his experience.

I should like to say I have tried a good many ways of introducing queens, but find none to equal this. I have tried this method on colonies that had queens just removed, up to colonies that had laying workers, and in every case it worked to perfection. I am sure we introduce more queens than any one else, and I expect to use this method entirely.

Medina, Ohio. J. E. MARCHANT.

We have generally recommended the cage method of introducing because it is handy, and beginners are usually successful with it. The veterans will, of course, practice the plan that will give them the best results.

FRAME-TONGS; WHEN THEY MAY BE A NECESSITY.

On pages 573 and '4 we have illustrated two styles of hive-pliers. Those shown on page 574 are very similar to those sold for many years by T. G. Newman & Son during the 70's and 80's. While it is true, as stated in our footnote, they have never been regarded very favorably by practical honey-producers, there are times when they can be used to great advantage. For example, the foul-brood inspector runs across all kinds of hives and brood-frames. Even if he encounters a modern hive with modern frames, there is a possibility that *that* hive has not been opened for several years. In any case, the inspector has a "job;" and sometimes he feels that nothing short of a crowbar and cold-chisel and a hatchet will make the brood-nest available for inspection. An ordinary pair of fingers will fail to remove any brood frame that has been gummed up in the brood-nest for the past five or six years, and a good steel hive-tool is not "in it." A pair of frame-tongs, as shown in this issue on page 574, would, undoubtedly, be of great assistance in affording a more secure grip on a refractory frame.

Of course, if the combs are built cross-wise, as they often are, nothing but a cold-chisel and a butcher-knife can be used; and even then a sledge-hammer or a crowbar might be more serviceable, not to overlook, of course, the always useful and indispensable bee-smoker.

CONVENTIONS FOR THIS WINTER.

If the National Beekeepers' Association could arrange dates for conventions, both State and local, it would make it possible for more speakers to attend. For instance, the editor of GLEANINGS would be glad to take in more of the meetings if the dates did not run so close together. In some cases the meetings are on the same day. Sometimes manufacturers are willing to make exhibits at these conventions. If these exhibits could be sent from point to point, one convention after another in rotation, it would save expense, both in the time of the man, railroad fare, and freight. We wish, therefore, to offer the suggestion that the secretaries of the various associations in the United States place all dates before the secretary or president of the National Bee-

keepers' Association. We feel sure that either one would be willing to arrange a scheme of dating that would accommodate every one.

Aside from the convenience of the manufacturers and editors of the various bee-papers, it would make it possible for Dr. E. F. Phillips, of the Bureau of Entomology, to be able to attend many more conventions than he is now able to do. His superiors would doubtless be glad to send him to a number of important meetings if the expense could be divided up between several conventions.

During the past year Dr. Phillips has gathered a great deal of valuable information; and if some of our important State conventions could secure his presence they would thereby materially increase the attendance. Under the present no-system haphazard scheme the editors of the various bee-papers can attend only a limited number of conventions. We respectfully suggest that President Gates, of the National Beekeepers' Association, take this matter under consideration.

Later.—Just as we go to press we have received a letter indorsing the plan. We will publish it in our next issue.

PROBABLE 50-PER-CENT REDUCTION IN THE TARIFF ON HONEY.

SEVERAL have been asking of late what the proposed duty is to be on honey in the new tariff bill now pending in Congress. We wrote to our Senator, Hon. Theodore E. Burton, and below is his reply:

My dear Mr. Root:—This is to acknowledge receipt of your letter of the 23d inst. with reference to the duty on honey. Under the so-called Payne-Aldrich law the duty was twenty cents per gallon. Under the bill now pending in Congress the duty is placed at ten cents per gallon. I think, from present indications, that the bill will go through practically in its present shape, and thus the duty will be reduced, as you say, 50 per cent.

With cordial regards I am

Yours very truly,

T. E. BURTON.

So far we have refrained from any discussion as to the probable effect the fifty-per-cent reduction would have on domestic honey as it would be difficult to make a forecast. We have not felt nor do we now believe that the proposed reduction is going to affect materially the sale of honey in this country. The West India product is all extracted, and much of it of an inferior quality. It is very clear that neither American comb honey nor table extracted would be affected. The only thing that might happen would be a reduction in the price of American honey for manufacturing purposes; but the production in this country, of this grade, is so enormous that we do not

see how it would suffer by way of competition with honey from the West Indies of the same grade. And even if it did, it will have the protection of probably a cent a pound, which, in our opinion, will be sufficient to protect our American producers.

WIRE FENCES FOR PRODUCING FANCY COMB HONEY.

It will be remembered that Mr. S. D. House, of Camillus, N. Y., has been advocating the Betsinger wire fence or separators for the production of comb honey, claiming that he gets better filling, and practically all the honey fancy. We had some supers made up on the Betsinger plan, and turned them over to our neighbor Vernon Burt, of Mallet Creek, about two years ago. Well, he tested them out, but, strangely enough, his bees built the combs against the wire and all through it. The honey was spoiled. The next year the results were not much better. But this year he told us he had some of the prettiest comb honey he ever produced. He showed two supers produced by the Betsinger wire separators, and it was about the prettiest honey we ever saw—all fancy, and every section perfect.

There is a great difference in bees. Some strains will build burr and brace combs in their brood-nests galore, and others will build very few. The former will build their nice comb honey up against the fences. One beekeeper remarked, "The best way to treat such bees as that is to pinch the head of their queen."

Well, it is possibly true that, when Mr. Burt tried out the Betsinger plan the first time, he was using bees that had a fondness for building burr and brace combs. The last time, he used a strain that is free from it, and he has secured beautiful comb honey.

A RETROSPECT; THE EDITOR WHO KNEW IT ALL.

WE have been furnishing editorial matter for this journal since 1885—28 long years; and yet we are glad to say that every day we find something new to learn, especially when we rub up against the bees constantly.

Some 25 years ago the editor of one of our bee papers, inclosing an editorial just before he discontinued the publication of his paper, made a statement to the effect that the art of keeping bees had reached its zenith. There was nothing more to learn, no improvements to make; and therefore he was about to discontinue the publication of his paper.

Those of our readers who have taken a bee journal for the last 25 years will probably take issue with the now defunct journal. No wonder it died. Let us see what has happened since that time:

The evolution of the large power honey-extractor; automatic reversing of combs; the steam uncapping-knife; the melting of cappings as fast as they come from the knife, and the separation of the wax automatically; the honey-pump; simplified and improved appliances for the production of comb honey; cut comb honey; bulk or chunk comb honey; the bee-escape; queen-excluders; new and better methods of dealing with the swarming problem; specialist beekeeping—that is, where one man is owner and proprietor of from five hundred to several thousand colonies; syndicated beekeeping, where great corporations in the tropics are producing honey almost by the shipload; the development of new bee territory; migratory beekeeping; shipping bees without combs; bee-disease laws in two-thirds of the States; apicultural stations; government apicultural work; back-lot beekeeping; pure honey in nearly every State in the Union, backed by federal and State pure-food laws, and last, but not least, millions and millions of dollars' worth of honey produced annually where only thousands were produced when that editor who knew it all said we had reached the zenith of honey production.

THE VENTILATED BEE-ESCAPE BOARD.

WE would call attention to an article by Mr. Arthur F. Hodgson, in this issue, page 577, on the subject of ventilated bee-escape boards. While the idea is not new (see GLEANINGS for 1892 and 1893), it is, nevertheless, good. There are two important advantages in the ventilated escape-board. One is the elimination of all possibility of the bees suffocating, and melting down the honey; and the other, having the honey warmed for the extractor as well as free from bees. In regard to the first named, a solid board escape, if it should clog up during hot weather, may kill all the bees above the super; and the intense heat developed by the suffocating bees will melt down the honey. The use of the wire cloth, as shown in this issue, permits free ventilation; and should the escape fail to operate for any reason, no harm would be done, either to the colony or to the bees.

The second reason, warm combs for the extractor, is very important, as every practical extracted-honey producer will recognize. Cold combs in cool weather are very hard to extract clean. In fact, it is almost impossible to get them clean. But combs

that have the heat of the cluster of bees, 98 Fah., will extract very readily.

A great many have objected to the use of bee-escapes on the ground that, after the supers are deserted, the combs are cold; and this would be true of solid board escapes. For that reason many large honey-producers have preferred to brush or shake the combs. If new honey is coming in at the time, shaking will scatter much of it on the ground and on the bees. Nor is this all. The bees crawl all over the ground, get under the trousers, and, of course, the operator is stung more or less. If the honey-flow ceases, there is danger of robbing; and last, but not least important, the bee-escape saves all interruption to the colony. Shaking or brushing stops work, and some little time will elapse before the bees get down to normal again. From every point of view the bee-escape method of freeing the bees from the comb is greatly to be preferred, providing the objections to such methods can be eliminated, and the Hodgson plan, as shown in this issue, does it.

HONEY-CROP CONDITIONS AND PRICES.

THE mass of reports that have been received from the central States shows that it has been unquestionably a good year for the production of clover honey. The peak of the yield seems to have centered down through the Ohio Valley, including Indiana and northward into southern Michigan and southern Ontario. Generally speaking, the yield decreases from that area, either east or west, north or south; but there are exceptions, for even in favored portions of the clover districts there have been almost complete failures; and in regions where the clover yield has been light, there has been an occasional record-breaking crop. In most of the New England States the season has been, perhaps, below the normal. In Eastern New York, Pennsylvania, and New Jersey the yield has been fair to poor. In parts of Illinois there have been good and poor yields. The same is true of Minnesota. In eastern Wisconsin the season has been good, and in the western part poor. Iowa seems to have had a fair yield in most places.

Taking it all in all, the aggregate production of clover will be above normal, for there have been record-breaking yields in favored localities. The price of clover extracted will perhaps be somewhat easier; but on fancy and No. 1 comb the prices ought to be up to normal, for we have never yet seen either too much fancy or No. 1 clover comb honey.

Very little basswood honey has been re-

ported anywhere in the clover belt, or elsewhere for that matter. This means that the clover this year will be all clover.

Our Mr. L. W. Boyden has just been making a trip through the West, looking up the honey situation. His report, in brief, is as follows:

My trip through the West was made in rather of a hurry, as it was necessary that I return here at an early date. At the same time, I visited quite a number of the larger producers in the Middle and Western States, and I am of the opinion that the honey crop will be larger in Colorado, Wyoming, Idaho, and Nevada than it has been for two or three years past.

Nevada and Idaho had heavy rains during July, which is unusual for that territory; but since then the weather has become very hot, thus insuring a heavy honey-flow.

The writer visited a number of very good localities in the West which are not at present being used by beekeepers; and if any one is considering moving westward, and desires information with reference to certain localities, I shall be pleased to give him what little information I have.

There are several new government projects which will be opened in the near future. This will give additional acreage for bees. Many ranches in certain sections are raising seed from alfalfa, alsike, and sweet clover. If one is fortunate in getting near one of these places he will be assured of a continuous honey-flow throughout the summer season.

The Ontario Beekeepers' Association has sent out a very complete report of honey-crop conditions. The average crop is 63 lbs. per colony, largely in the southwestern counties. The eastern counties have practically no honey; but the total yield so far reported is 1,618,000 lbs. from 543 beekeepers out of 700. In the matter of crop reports, our neighbors across the line have it down to a fine science.

The season in Southern California has been poor. In the northern and central portions of the State, conditions have been better. In Northern California there will be about half a crop. In the Mesilla Valley, New Mexico, the year has been a poor one. Taking it all in all, the failure of the crop in California and New Mexico, and in some parts of the Western States, will make Western honey, perhaps, a little scarcer than usual; and this shortage will have a tendency to make prices on Eastern honey more stable. Just what the real effect is going to be, remains to be determined. But certain it is that the Western beekeepers should make an effort to sell west of the Mississippi as far as possible.

There will be danger this year that a large number of beekeepers will dump their honey on the market all at one time. A concerted action would avert this trouble, and the large producers would do well to get in touch with other large producers and associations to avoid a congestion of the market in any one point.

TELEGRAPHIC REPORTS FROM COLORADO.

We have made arrangements with Mr. Frank Rauchfuss, Manager of the Colorado Honey-producers' Association, to furnish crop reports by wire on the 9th and 24th of each month. Mr. Rauchfuss is in the heart of the alfalfa country, and has unusual facilities for getting at the facts. His first report is as follows:

On the eastern slope of this State conditions have improved the past two weeks; flow has been from fair to good in most localities; quality of honey fine; excessive swarming will cut down yield; western slope reports similar crop conditions.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION,
Frank Rauchfuss, Manager.

Denver, Aug. 9.

THE IMPORTANCE OF ACCURACY IN MARKET REPORTS; PRICES FOR THIS YEAR.

ELSEWHERE in this issue we endeavor to give an unbiased and accurate report of crop conditions based on reports of our men in the field, and on letters received from our correspondents and customers all over the United States and Canada. Our facilities for obtaining this information are the best in the country. We have proceeded on the assumption that *exact conditions* must be stated. If, for example, the yield has been heavy in certain localities, that fact should be presented. To hold it back or ignore it with the view of keeping up the market would be a serious mistake. The effect could be only temporary at best. In the end, as soon as the honey began to be dumped in the great centers, the market would begin to tumble, and the momentum thus acquired in the tumble would follow with a crash. It is much better to have the market a little easier, *and hold it at that point*, than to have it take a sudden drop. At present we do not think that prices, except on clover extracted, and possibly on alfalfa extracted, should be below normal; and even these honeys in the liquid form should sell for nearly if not quite what they sold for last year. In view of the partial failure of honey in the South and Southwest, in California and the eastern tier of States clear up into New England, and the fact, too, that clover this year is strictly clover, and not a clover and basswood mixed, should have a tendency to hold prices up. A pure clover will always bring a better price than clover and basswood mixed.

SOME REMARKABLE TESTIMONY SHOWING THE VALUE OF BEES IN FERTILIZING THE BLOSSOMS OF FRUIT-TREES.

In the *Country Gentleman* for May 24 appears an article by William Harper Dean telling of the remarkable success of three

brothers in growing and storing and marketing their fruit. The story is as interesting as the Arabian Nights, and the feats accomplished quite as wonderful; but this story, unlike the Arabian Nights, is true, as it relates *actual* performances. Mr. Dean goes on to recite the early struggles of the father of the three brothers who have built on the splendid foundation he laid; of how this father in his younger days had a vision of growing fruit on a large scale; of the heroic struggle he made; of how he began and failed; lost every cent he had; of how he worked out to make more money, and started again and failed. Most men would have been discouraged and given up the job, feeling that he was a miserable failure; but not so with John Repp. He went at it again.

In the mean time he was raising a family of three boys, and was lucky enough to have a wife who had the same kind of pluck he had. Of course these boys were brought up right; that is, they learned how to work. They profited by their father's early experience, by his repeated failures and occasional successes. The father struggled on; and just as he was on the point of realizing the vision of his early days he died. Had it not been for the indomitable courage that appears to have been bred into the boys, this story as it appears in the *Country Gentleman* would never have been written. But the boys were made of the same stuff as their father. That dearly bought experience that spelled apparent failure for the old gentleman did not come amiss. At all events, the boys are now proprietors of an 800-acre fruit farm, mammoth cold-storage plant, where ten thousand bushels of fruit can be stored and kept till the market is right, and an office where the records and the business of the concern are taken care of.

Albert Repp is the grower who is on the job from sunrise to sunset. Charles Repp is the man who keeps the fruit in that 10,000-barrel storage-plant. Joseph Repp, in Philadelphia, is the merchant who sells the stuff. All three make up what is known as the Repp Brothers, located in Gloucester Co., N. J., and a splendid working team they are.

Well, what has all this to do with bee-keeping? Read the following extracts from the interview Mr. Dean had with Albert Repp, the grower:

I had walked the mile or so from Pitman to seek out this Albert Repp who grows the things for Repp Brothers, and found him returning to his home from overlooking the spraying of certain blocks of trees in the orchards.

"Too windy," he remarked snappily. "We'll stop

spraying until the air steadies a bit. Yep, spraying is no fool's job—it's got to be done right or not at all. We're spraying for peach scab now, and have already been after the codling moth in the apples. Look at the bloom on those pears. Isn't it a dandy?"

It was. I looked through a fairyland of blossoms on correctly pruned trees, in a weedless, grassless, thoroughly worked soil covered with shedding blossoms like confetti after a carnival. It was good for the heart to see such a sight.

MUST HAVE BEES IN AN ORCHARD.

"And if crying would do any good," mused Albert Repp, seeming to forget business for a moment as he, too, gazed at the sight, "I'd cry an hour to bring out the sun so the bees could get to work. It's too cool for them to-day."

"You have an apiary in connection with your farm?" I ventured.

He looked astounded at my question. "Of course! Couldn't do without them. I never take a pound of their honey. All I want them to do is to pollinate the blossoms. I'd as soon think of managing this orchard without a single spray-pump as to be without bees. I've got fifty colonies now, and am building up the apiary each year. There they are—look at them!"

The hives stood in perfect rows, as white as the blossoms above them. But there seemed to be a superabundance of bees, I thought. I mentioned this.

"Not with 450 acres of orchard," he explained: "You see we've got bearing orchards of apples, peaches, and pears, with many varieties of each. Now when you've got a new variety of one of these blooming while others are just budding, it gives the bees and the spray gangs all they can do to keep up with them."

Beekeepers would do well to cut this out and paste it in their honey-houses, or at least put it where they can bring it to the attention of farmers and fruit-growers in their vicinity. Those who have a scheme of outyards should hunt up the fruit-growers, and see if they can not make some arrangement whereby the fruit-growers will ask to have the bees put on their places rather than compel the beekeeper to *pay* for the privilege. For example, at one of our outyards a few behind-the-times grape-growers have made a protest that our bees will damage their grapes. If these fellows could know what these Repp brothers (and we will see that they do) are doing it might change their opinion.

This article is so interesting that we suggest that the readers of this journal hunt up a copy of the *Country Gentleman* for May 24, from which we have made the above extract; and if you can not find one you had better send to the Curtis Publishing Co., Philadelphia, inclosing ten cents for a copy. You had better get it, even if it costs a dollar. It is worth any man's while to read the early struggles of John Repp, and see how when what appeared to be failures spelled the biggest kind of success for the boys who took hold of the plow-handles when the father, possibly worn out, was stricken by death. Such a story should be an inspiration to any young man, especially if he has met with some reverses.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

BEE sugar has its certificate of character, p. 398, but I'd feel surer about it if the *British Bee Journal* would endorse that certificate.

P. C. CHADWICK, your head's level on the sugar question, p. 404. I suspect there's many a beekeeper thinks he's making money by feeding sugar when he's losing.

HONEY-PLANTS luxuriant this year. Plenty of white-clover blossoms an inch in diameter, with stems more than a foot long, and one dandelion stem I measured was 30½ inches long.

LET me endorse the use of dummies recommended by G. M. Doolittle, p. 442. I have some just such as he describes. Others, instead of being an inch thick, are ¾ thick. These I like better, although it requires a few more of them. They are easier to handle if an inch shorter than the frames, and seem to work just as well.

MR. EDITOR, likely enough you are right, p. 481, that in grading section honey more than two different weights are needed. For the sake of illustration, let us suppose that the three weights needed are 12, 13, and 14 ounces. My idea is that there must be three different scales—not one pair of scales capable of weighing all three weights, but three separate scales, one weighing 12 ounces and nothing else; another 13 ounces, and another 14 ounces. The simplest possible arrangement will answer—just a bar with a weight on one end and something to lay a section on at the other end. You see it would take too much time to have scales that would have to be changed every time a different weight was needed. And surely a balance weighing only one single weight could be made for less than one weighing different weights. [Having three scales would be more expensive and more complicated than having one pair of scales that would instantly record 12, 13, 14 ounces, or any other weight at a mere glance. We do not believe there are any scales on the market such as you have in mind; and the demand for them would be so limited that the cost would be prohibitive. The only thing to do is to take what is already on the market and make the best of it.—ED.]

MR. EDITOR, let's see if we can not come to terms about that winter-nest business. You ask, p. 482, that I shall not confuse outdoor and indoor wintering. I recognize that outdoor wintering is under discussion, and not only outdoor but Canada outdoor; for if you go far enough south, where is the difference between outdoor and my cellar?

All the same, if a cluster of bees in cellar can hang below bottom-bars, what reason is there that they can't do the same outdoors? You are entirely right in thinking that solid slabs of honey allowing layers of bees only ¼ inch thick will not do. Even in cellar I should expect ¼-inch layers to perish. But a 2-inch layer is another story. With a 2-inch space under the bottom-bars (a deeper space might be better), allowing the bees to cluster clear down to the bottom-board, there ought to be no trouble about their keeping one another warm. I wonder if you've thought of this: Solid slabs, allowing ¼-inch layers of bees *only*, are bad; empty combs are bad after the same kind, but much less in degree; the ideal is a solid cluster of bees with nothing interposing, directly under a solid mass of honey. And this refers to the severest climate outdoors. [When we speak of outdoor wintering it would, perhaps, be well to bear in mind that it means all degrees of temperature—high winds, no wind, wet snow, and light snow. We do not believe it would be practicable for a cluster to winter under the frames for outdoor wintering. Even a winter with a temperature of only 50 degrees would drive the bees up between the frames. And when it got down to zero or even below, a cluster in front of the entrance on a level with the bottom-board would freeze to death. On the other hand, in a cellar temperature anywhere from 40 to 60 degrees, at either extreme a cluster could be maintained below the frames. A winter nest for cellar wintering is not important; but we believe it is vital in outdoor wintering. We should expect, in our locality at least, that a cluster of bees would not stay in the space between the bottom-bars and bottom-boards in outdoor wintering, but would move up three or four inches on the combs. As the winter progresses, the winter nest would move upward with the bees; then move backward to the back end of the hive. That is precisely what takes place in our outdoor-wintered colonies. The writer has opened up hundreds of colonies at all times during mid-winter; but we have never yet found a cluster below the frames. We should like to know if there was ever a case recorded of that kind.]

In early fall it may be practicable to give a colony nothing but solid combs; but let that colony have its own sweet will and it will soon make up a winter nest just over the entrance and about two inches above it, in our locality. This would be during November and December.—ED.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

The honey crop in this section will be light, owing to severe drouth. I hope it may be better in other parts of the State.

* * *

This year I have used one-piece sections for the first time. Their only fault so far has been that most of those filled with honey appear to be a little diamond-shaped, or not quite square.

* * *

"Once you have foul brood you always have it," says E. D. Townsend in the *Review*. Yes and no. If you are a shiftless, thriftless beekeeper, yes; and if you are a worker and pusher, and you have a fairly good foul-brood law, I say no.

* * *

Mr. Chadwick, of California, on p. 250, April 15, refers to the ignorance of beekeepers. Inspecting is as good as a post-graduate course in beekeeping, and I think it is better. The inspector will learn a great many things not found in the books or journals.

* * *

In Mr. E. S. Miles' article on feeding back extracted honey for finishing sections, p. 415, June 15, he says that in two or three weeks' time between clover and heartsease he usually gets from 15 to 25 supers finished per colony. This would be more than a super a day. Is not there some mistake about this?

* * *

Dr. Miller, you say, p. 418, June 15, that if you find a colony needing treatment, if you wish to prevent swarming you remove the queen and kill all the queen-cells, and again in ten days kill all queen-cells and introduce a laying queen. Now, don't you sometimes get a young queen hatched in ten days that will make you trouble?

* * *

It is undoubtedly true, as Mr. Doolittle says, p. 405, June 15, that in an exceptionally good flow of honey there would be a waste of wax where foundation is furnished so as to fill sections with it, with the result that the foundation would not all be drawn out. But in practice I find such occasions very rare, while the necessity for full sheets of foundation in the sections in order to get them well filled with combs and honey is a constant factor in the successful production of comb honey.

* * *

Mr. Byer refers on p. 412 to the pussy willow as credited with not yielding honey.

In this locality at least, this is not true, as it produces its seed on its pistillate plants, which produce no pollen, and must be visited by bees after having visited staminate flowers in order to carry the pollen. Honey would be necessary to attract the bees to these flowers. Mr. Doolittle may have noticed bees working on the staminate flowers, and have drawn his conclusions from the fact that the bees got no honey from them, and failed to notice them when at work on the pistillate flowers.

* * *

IS ALFALFA POLLINATED BY BEES?

"Is alfalfa pollinated by bees?" is asked on p. 267, April 15, with facts given in answer to the question. A year ago, while in Washington, I became very much interested in the experimental work of the Department of Agriculture in the introduction and also the production of new varieties by hybridization of colonies. The superintendent, whom I looked up, said that I might make some inquiries, gave me to understand that honeybees are of little or no value in the fertilization of alfalfa, as they are unable to "trip" the flowers. He showed me a large number of hybrids, one of which is likely to prove of great value to the farmers of the country. He told me of varieties that are likely to prove hardy even in the climate of North Dakota.

* * *

I found a beekeeper two years ago among whose bees there was some disease; but it was too late to treat them. I went again last spring, and with him opened every hive and showed him all about how to treat the disease. Again, this spring, I tried to find him to look over the yard; but when he found I wanted him he slipped away. His yard was one of the most slipshod I ever saw, and I could not blame him. Well, nearly half of his hives contained disease.

I went to visit another beekeeper who had a badly diseased yard two years ago. He met me, his face beaming like the rising sun. "I want you to come out to see my yard of bees," said he. "I have got the prettiest yard of bees in the county," and I want you to look at it." The hives were all painted, and every thing was neat and trim.

"Got any foul brood yet?" I inquired.

"No," said he; "I have gotten rid of all of it."

Of course he had. It doesn't stay with *such beekeepers.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

Some feeding has already begun in a small way, but will not open up in earnest for a few weeks.

* * *

Pickled (or sac) brood seems to have had quite an inning this season. Many reports have reached me of the prevalence of this disease over most of the southern part of the State.

* * *

I have lost several letters containing stamps for reply, among which was one from a gentleman in Nebraska, another from a lady in Washington or Oregon, and another from a lady in Banning, Cal. These parties will do me a favor by writing again, and I will try to give them the desired information.

* * *

July 26, fog and cold is the program at this writing, with some rain in the foot hills and mountain regions. I have never seen a season before with so much fog and cloudy weather in midsummer. To-day the temperature has been 69 at the highest and 59 at the lowest. Last week we had a rain, and for the past two weeks we have had regular winter weather while we were reading daily of the heat prostrations in the East. I believe that, if the season had been moist enough to produce a honey crop, there would have been some *beekeepers* prostrated because of the time that would have been lost by the bees on account of the cold cloudy summer.

* * *

I have had more trouble this season introducing queens than at any former time within my memory. Last year I removed the old queen and placed the introducing-cage with the new queen in the hive at one operation, letting the bees release her at will, and I did not lose a queen. But this season I found that the only safe plan has been to make the colony queenless until the cells are well advanced, then to cut off the cells and give to the colony the cage containing the new queen, to be released by the bees. I am completely at sea as to the reason for the failure of the first plan, conditions being almost identical with the conditions of last year at introducing time. Some queer things happen at times in this line. Last spring, while working at the apiary with Mr. Byron Crawford, my helper, in some way we lost a queen out of one of the many hives we had handled. There was a question as to what to do with her. Crawford wanted to roll her in honey and put

her in a fertile-worker colony, so I consented, and he did so, with the result that she was cleaned up and went to work.

* * *

In reading the reports of crop conditions in the July 15th issue I notice that in some places the honey crop was cut short by two or three weeks of dry weather in the white-clover belt, and I know full well what that means to the eastern beekeeper from past experience of my own. In this part of California, if we have had a heavy rainfall through the winter and up to the middle of April we pay no attention to two or three weeks or that many months of dry weather. The last rain we had in 1905 came the first of May, yet every thing yielded in its season. We extracted 30 cases from 110 colonies September 12. They filled full again before winter; and the way they came out the next spring with hives full of bees was pleasing indeed. Give us plenty of rain in the winter and we would, but for the cold foggy weather when the honey-flow is on, be ready to join the "Don't Worry Club" for a while.

* * *

Recently I made a trip into the edge of the mountains to visit a friend. During my stay I discovered a new-style "let-alone hive." It was, as I remember, a soap-box into which the bees had been dumped with some thin boards covered over the top, on which was a rock of some size. The entrance was two auger-holes, but most of the bees were going in and out under the cover boards. I concluded to make an examination, so I approached the hive as I would one in my own yard. I had reached a point about six feet from the hive when I decided to make a hasty retreat. I turned my head in time to get my eyes out of the way, but the back of my head was about as full of bees as my hair would hold. I let them alone, and have been wishing ever since that I had them where I could spend about fifteen minutes every day smoking them. There is no question in my mind but that bees get used to having people around. I have hives within 15 feet of my back door-steps, around which my children play day after day, and they rarely get stung. If I bring in a colony from the apiary at any time, it is always necessary to caution the family to go easy around them until they get used to seeing us pass to and fro. This hive I have just spoken of was in a remote place on the farm, and the only thing in the bee line to be found.

Beekkeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

A "FIGHT" FOR NET-WEIGHT PACKAGES.

Much honey is being sent to market just now in receptacles that do not hold the stipulated weight as given on the shipping-tags and as indicated on the invoices sent by the producer to the buyer. I question whether this is right in the first place, and whether it is a safe plan to follow. It must be only a matter of time when the law governing the proper weight of the contents of a package will be looked after by the pure-food authorities, and it seems to me that it would be better if beekeepers would remedy this matter before any trouble comes.

One element of unfairness is that some of the larger producers are required to put up their honey in net-weight packages, while others do not do so. The extra weight over the short weights of many of the smaller producers is a big item to us who ship from 70,000 to 100,000 pounds. While it is easy enough to find buyers for a small lot of honey here and there to take care of quite a number of these short-weight lots, yet it is a much greater item to dispose of big amounts of honey direct to a few large buyers who maintain that they must require full-weight packages.

I am aware of the fact that a few shippers do oppose our "fight," as they term it, for net-weight packages. We have been assured by several of them that they agree with us that we are right in our efforts, and that they will immediately step in line when the change to net-weight packages is obtained. In a joking way it was asserted that I was bringing a great hardship on the numerous beekeepers who were making a practice of shipping short-weight packages year after year. But to be fair in the matter, the only remedy would be to settle upon a full net-weight package all around. And it is to be hoped that this trouble will be remedied once for all time when our next year's honey-shipping season opens. Let's have a fair and square deal all around.

* * *

BEEKEEPERS, GET TOGETHER MORE!

Never before has there been the necessity of beekeepers getting closer together for the discussion of their welfare, crop results, and marketing, than this year. There seems to be very little effort on the part of the great number of beekeepers to strive to ascertain the crop conditions and the price at which honey should be sold, early in the season, so that the crop may not be sold too low. There is no reason at all, in my mind, why the Texas honey crop should not have brought at least half a cent per pound more

than it has brought. The entire Texas crop is a short one, and the demand has been most excellent. Besides this, the quality of the honey was better, as a rule, than last year. All in all, it should have brought a little better price than last year, because it was worth more, and the demand for it at the higher price was there. I know this from the simple fact that I could have sold any quantity of honey at the higher price if I had had it, and that, too, in spite of the lower prices that were maintained by others who market a great deal of honey.

The unfairness of selling lower than the price that ought to reign is very annoying to the beekeeper who is striving to maintain good prices, when some of his customers complain that his price is half a cent or a cent higher than the price at which somebody else is now offering his honey. Especially is this annoying when such a customer has already placed his orders for the year, and more so if this customer has been one of long standing, buying a great deal of honey year after year. In a few instances I have been required to cancel the orders, as I have made it a rule not to come down with the price that I found, through careful study and investigation, was the fair and proper one to be maintained.

Of course, it is hard to give up an old customer, and it is brought about only by the beekeeper who not only fails to recognize the price that ought to be maintained, but who is only too ready to plunk his crop on the market at a lower price in order to get rid of it. The jobber and the retailer get the benefit of this lower price, we have found, in that the retail price is about the same whether the beekeepers get half a cent more or that much less than the general market price. The loss to the beekeepers of Texas, on the other hand, is enormous. Half a cent per pound added to the price of all the honey that is sold throughout a single honey season amounts to a great deal. And this loss is occasioned by no other reason than the lower level set by the careless and the ignorant beekeeper.

Therefore it is high time that the beekeepers should get together and discuss these matters. It is not actually necessary to organize the beekeepers into a selling organization at the start, but frequent meetings, or even visits, among the beekeepers of every beekeeping center, for the discussion of crop conditions, and the prices that ought to be maintained, in accordance with the prevailing crop conditions and the market, would help a great deal.

Conversations with Doolittle

At Borodino, New York.

QUESTIONS ANSWERED.

A correspondent writes, "Did you read on page 503, GLEANINGS for July 15, that the first queen-cell is 'likely to hatch on the ninth day from the time the prime swarm issues'? Is that correct? From my observation I find that, as a rule, the prime swarm issues with the sealing of the first cell, and also that, as a rule, all queens emerge from their cells in from seven to seven and one-half days after the cells are sealed over. Also that, when every thing is favorable, the second swarm, or first after-swarm, issues on the ninth day after the first or prime swarm. What has been your experience?"

If I am correct, it was Moses Quinby who gave the rule that three days after the egg is laid in the queen-cell this egg hatches into a minute larva. It is fed by the nurse bees for six days, when the cell is sealed over. Seven days after the sealing of the cell the queen emerges; and two days later, when every thing is favorable, and an after-swarm is desired by the bees, the first of the after-swarms issues. That is to say, where the prime swarm issues with the capping of the first queen-cell the first of the after-swarms will issue nine days later. In the development of brood, and in all of this swarming matter, cool, rainy, bad weather, retards; and hot pleasant weather, with a good nectar yield, accelerates. But the data given will be found accurate enough for all practical purposes. And my forty-five years of experience has corroborated and proved that Quinby was correct. Of course, in my later years of work with the bees very few colonies have been allowed to have their own way in this matter of swarming; but the few that have thus been allowed have proven that bees swarm very much in this twentieth century, as they did half a century ago, when Quinby was conducting his experiments and observations.

QUESTION NO. 2.

"A swarm came out one day, clustered, and was hived. In the afternoon the bees came out in a straggling swarm and went back to the parent hive, leaving a bunch of bees about as large as a teacup. These remained a day or two, when they swarmed out and clustered. I found the queen with them. Why did most of the bees leave their queen and go back?"

The above is one of those perplexing occurrences which occasionally take place in a large apiary where natural swarming is allowed. The general cause is, that a few

strange bees attach themselves, cluster with the swarm, or go in with the swarm when the bees are being put in the new hive. And because of the presence of the strange bees, the bees of the swarm, or a small portion of them, ball the queen either for safe keeping or for some other purpose. When the queen of the newly hived swarm is thus balled, the bees seem to think that they have lost their queen; and after vain attempts to find her in or about the hive they begin returning to the parent hive, going a few at a time. It sometimes takes the larger part of an hour for all the dissatisfied ones to return. But there are always left from half a pint to a quart of those in the ball, and those near enough to realize that their queen is there which do not return. At about this stage of the proceedings, good common sense seems to take possession of those which remain, and the queen is allowed her liberty, when, if nectar is coming in, they go on and do the best they can at making a colony; or if a bad spell of weather follows, and they are likely to starve, they will swarm out. If, after they begin to return, they are stopped from going home, they will try to go into other hives.

In this way I used to find that a large proportion of them were killed. Finally I learned how to keep them in the hive where I had put them. When I found a newly hived swarm in agitation about the entrance, with a few bees returning to the parent hive, I would open the hive containing the swarm, and, finding the ball of bees, smoke them till they released the queen. She was then placed in a long wire-cloth cage which would reach clear across the frames. After closing the hive, an old bag or cloth of some kind was thrown over the top of the cage and frames as a temporary affair. A hum of contentment was always the result. As the bees had access to the queen between every frame-range they all settled down to quiet and work, the same as if the queen had never been balled. The next morning I would release the queen, remove the cage, put on the supers, and all would go well. At first, when hunting the queen I would put her into a common small cage and hang this cage by means of a wire down in the center of the hive, where no combs or frames of full foundation were used; but in about half the time this would not satisfy the bees. They would show their dislike by balling the cage so that the desired results would not be attained.

General Correspondence

IMPRESSIONS AFTER ONE YEAR'S EXPERIENCE IN BEEKEEPING

BY ANDREW J. MONTGOMERY

Through no plan or preference of my own I became a beekeeper in a small way. Some months before, inflammatory rheumatism had sent me to the hospital. There the "hot air" treatment was successfully given; and when I returned the rheumatism was gone, for the time being at least. That fall two men in my congregation (I am the pastor of a suburban church) made me a present of a colony of bees. Antecedently I had no more use for bees than for rattlesnakes, and would have given both the equal courtesy of keeping at a safe distance. But with a hive located on one's own back lot he is confronted with a condition, not a theory. Fortunately, winter was at hand, and that gave time to make the necessary mental readjustments. Several times during the early winter I observed the bees taking a flight, but it was done in the same manner Moses saw the land of promise—afar off. When spring came, one of the donors opened the hive and initiated me into the mysteries of caring for the colony of bees. The first year was successful. I have three colonies now, and secured 72 sections of honey. That is good enough for a beginner.

The first year taught a good many lessons. Some of these, no doubt, will be modified to a greater or less extent with more real experience. But there is a vividness about first impressions which rarely ceases. It is said that, if a man gets printer's ink well rubbed into his hands, he is never able to wash it off. Is not the same true of beekeeping? Can propolis ever be removed from the hands, especially if one has been inoculated, in a generous fashion, with the virus of bee-stings? There is a quality of fatalism about the business. Whoever would not be a beekeeper had better never allow himself any experiments with the art. The disease of melissitis (peace to the shade of Noah Webster) is in most cases incurable.

For the ordinary professional man the care of bees ought not to be despised as a form of health insurance. The mental relaxation, the employment of a different set of brain cells, and the attempt to solve the hundred and one different and also difficult problems which arise during the brood and honey season are a perfect God-send to the man the greater part of whose working hours is spent in the office. I have some

friends who are physicians who sniff when the sting cure for rheumatism is mentioned. May be they are right. But since I have been stung generously by the bees there has been no recurrence of the dreaded rheumatism. I notice that many of my beekeeping friends are in the habit of saying that a nervous person ought not to go near bees, nor should such a person ever try to take care of them. It occurs to me that the nervous man is the very person who should learn to handle bees. He is most likely to learn his lost art of deliberateness, which is the secret, very largely, of self-control.

The mode of life of a colony of bees is a first-hand experiment in socialism. They have the social sense developed to the last degree. They have the community sense in an exaggerated form, so that the self sense is altogether lost. Therefore I was intensely interested last fall in watching the outworking of some of their socialistic principles. First, I saw young husky workers drag out bees that had grown gray in the service, figuratively; summarily eject them from the community, and leave them to their fate, which was death. Then I noticed the fate of the drones. A small worker like a little tugboat would appear on the landing-board, hitched to the wing of a big drone, and headed out. Well, that is not the spirit of Tennyson's "Crossing the Bar." The bees have relentlessly followed socialism to its logical outcome; and that is, the destruction of the non-producers. After my first summer's experience with the bees I am less inclined toward socialistic measures than ever before. If our chief aim in life is to produce producers only, then the elimination of the non-producer is, of course, required. That may be the implication of theoretical socialism, but it is not the spirit of Christianity.

The perennial freshness of the interest in the keeping of bees is, I fancy, largely due to life and mystery. A hive bursting out with bees is a sight to gladden the heart of any one. There is life abounding, exuberant. The ancient Egyptians used the bee as a hieroglyphic sign to indicate royalty.

As the Egyptians used their bees
To express their ancient Pharaohs.

—Hudibras.

Incidentally, no doubt this is the origin of that odd expression, the "king bee." The bee was the royal symbol, we are told, because the king had honey to give as a reward, and a sting as punishment to the unworthy. But it seems to me that the real reason why this insect was chosen as the

royal emblem is that it is a symbol of life. The glory of a king is the swarming multitudes over which he reigns. And the populousness of the hive must have suggested itself as a fitting emblem of the king, the head of their national life.

Then add the fascination of mystery to the interest which we all have in life in its varied forms. After all the light which we possess is gathered together, the mystery of the things which we do not yet know about bees is very great. There are many things about the habits and life-history of the bee for which light is sought. And the problems of bee culture are elusive, because, as it seems to a beginner, there are so many things which are known only in a practical way and not scientifically. For example, Albin Platz says, page 23, Jan. 1, "Don't practice stimulative feeding in the spring." My single colony came through the winter weak. I am satisfied I should have received little or no surplus honey without stimulative feeding. I used the Opfer feeder, which will take only five ounces of sweetened water at a time. Almost immediately the reaction under this stimulus was visible. The queen got busy. With the number of sections of comb honey already indicated, with one nucleus taken off and a brood-frame taken out to strengthen another weak nucleus, I feel that stimulative feeding is a good thing. But this is simply matching experience against experience. If the Department of Agriculture would permanently maintain a great experimental apiary, and employ the laboratory methods of modern science, light might be gained on some of the really great problems of bee culture. I do not now refer, of course, to stimulative feeding, which is not so vital as many other problems.

Oak Park, Ill.

LECTURES ON BEES IN BAVARIA

BY J. A. HEBERLE

The organization of beekeepers of Markt Oberdorf and the surrounding country arranged for a short course of instruction in beekeeping free, not only to the members of the organization, but outsiders also were invited. Mr. C. Hofmann, Munich, in charge of apiculture in Bavaria, conducted the course. Being so late in the season, practical work in the apiary had to be omitted. First was given a talk on the history of beekeeping in general, and especially in Bavaria.

IMPORTANCE OF BEEKEEPING.

The value of colonies, wax, and honey, based on the number of colonies in 1907,

was estimated at two and a half million of dollars—quite a sum for so small a country. For this reason the government encourages and fosters beekeeping in every way. The service bees render to agriculture by fertilizing the flora is great. Some one has ventured to estimate the value per colony at \$20.00. He thought, probably, he would rather lose the game by playing a card too many, as Sancho Panza said. The flowers secrete nectar so the bees and other insects will visit them and bring and carry away the needed pollen. The nectar is usually within, at the base of the flower; and while the bee or other insect endeavors to get to the sweet, the pollen sticks to the hairy garment of the bee; and when she touches the pistil of the flower a few of the fine grains of pollen do the work. The "Wiesen Salbei," a salvia, has a peculiar construction. In order to get to the nectar the bee has to push the short end of a lever. On the long end is the stamen. The bee pushes the button and does the rest. We see how wise it is that the bee, while gathering nectar or pollen, visits but one variety of flower or blossoms, otherwise the probability of bringing the needed pollen to the right place would be greatly lessened.

BEES IN HOT-HOUSES TO POLLENIZE APRICOT BLOSSOMS.

The lecturer mentioned a very interesting case. The city of Nuernberg has a number of hot-houses in which apricots are raised. These hot-houses are rented to a gardener. This gardener, with his assistants, used to fertilize the blossoms with brushes, but they had only moderate success. Once, through a broken pane of glass, some bees got into one of the hot-houses. It was found that in this house where the bees had fertilized the blossoms the trees had set much more fruit than the trees that were artificially fertilized. After that, bees were kept in the hot-houses during blossoming time. The bees do the job cheaper and much better—in fact, too well, as too much fruit sets. It was further found that the time of blossoming was much shortened. This is a decided advantage, because the weather and the various enemies have less chance to do damage. It is known that, after the fertilization is complete, flowers and blossoms soon cease to secrete nectar, and insects are no longer needed. The plant makes use of the sap (its blood) for the ultimate purpose—the production of seed, etc.

ANATOMY.

The *chitin skelet*, as well as the interior organs, were thoroughly discussed. Drawings on the black-board, charts, and a model, helped to elucidate the subject. The

anatomy and physiology of the bee is very interesting and complicated. The antennæ alone have many thousands of organs of sense. The tongue is part of a complicated suction apparatus. The legs show a marvelous adaptability for walking on the ceiling or on glass. They can hold a great weight, as is shown when bees collect pollen in the basket to carry it home to the babies. The stinging apparatus is wonderfully made. The novice will readily conceive that it is fearfully made.

VARIOUS RACES COMPARED.

Of the many varieties of bees, the Italian, Carniolan, and the common black bee were mentioned, and the character of each described. The Italian begins too early to rear brood. We have here much bad weather in spring, even in late spring. The extensive brood-nest entices the bees to untimely errands for water and pollen; and many, owing to the inclemency of the weather, will not be able to return; consequently much energy is wasted, and the colonies at the beginning of the honey-flow are not as populous as they ought to be, and the result is a deficiency of the surplus. It is also alleged that the Italians do not winter well. I have not been able to test these claims. I have imported several queens at different times from the United States, but the queens seem to have suffered so much by the long confinement and the hardships of the voyage that they were not qualified for any thing. However, I think the descendants might be all right. Only one queen survived the winter. The trial would have to be made by testing from four to six at one time, and early enough in the season to raise some queens to replace those which seem unable to pass the winter.

The Carniolans stand the winter very well; are very gentle and industrious; but owing to their swarming propensity they often fail to give surplus when the common black bees do. This is particularly noticeable in poor seasons. The common black bees seem best adapted to this climate. They moderate or stop brood-rearing very promptly according to weather and season. They make their surplus more by judicious economy than zeal in gathering—at least it seems that the Carniolan is just as industrious. So far as I know, there is not one Italian colony for many miles around here—say not one in ten thousand. In other parts of Bavaria or Germany there are some, but not many. Here we have blacks and Carniolans, mostly mixed breed of the two. The principal disadvantage of the mixed breed, I think, is that they do not transmit their good qualities to their progeny as well as pure-bred varieties. Of

course this law of heredity is as true of the higher animals, if not more so.

In this report I have given an outline of the topics that were treated more or less fully by the instructor.

The metamorphosis from the egg to the grown insect was illustrated, and to the practical bearings special attention was called under the head of "How bees should be handled; the stinging of bees, and protection against it; convenient way to feed bees, and when to feed; preparation of hive and comb for moving; the various hives and frames in common use; bee-houses (bees are kept here in bee-houses, just as the reverse is true in the United States); utensils and apparatus were shown and explained; combs and frames (the wiring of frames was shown); how to manage the bees at different seasons in order to obtain the best possible results; the selection of colonies for breeding; queen-rearing; diseases of bees, especially foul brood; and, last, the enemies of bees.

This short course was a success. Mr. Hofmann was congratulated from all sides. He is well qualified and well equipped to hold such courses. Next spring we shall have two days of practical work in the apiary and in queen-rearing.

Markt Oberdorf, Bavaria.

GETTING SLUMGUM FROM THE SOLAR WAX-EXTRACTOR

BY R. F. HOLTERMANN

For years it has been a puzzle to me how to clean out the refuse which is left in the wire-cloth basket in the solar wax-extractor. This has been particularly puzzling to me since the yield from the out-apiaries has been on the increase. As a result we have often been away when this refuse was still warm from the sun. Or if we were not away, we had returned from a day's work somewhere else, and wanted to eat our supper. After a good day's work I did not feel like asking or making any one attend to this matter. I may say that I have never been an advocate of long hours in work. To work fairly rapidly with an average of ten hours' work a day, or even a little less, is ample.

This year I hit upon the idea of heating the wire-cloth basket with the contained refuse over a fairly hot fire—a minute or two will do it. The matter softens first next to the wire, and comes off in a solid cake, and I do not believe there is a better way of cleaning the basket. Try it, and I believe you will think the same.

Brantford, Canada.

FLORIDA APIARY OF W. J. DRUMWRIGHT

BY M. L. BREWER

Each year we spend our vacation in Florida, about twelve miles below where A.I. Root has his winter home. While there it is always a pleasure to meet the beekeepers of that section. One that I met in the winter of 1910, Mr. W.J. Drumwright, is one of the veterans. It is a pleasure to talk with him. Mr. Drumwright went to Florida a little more than thirty years ago with his family, himself broken in health. He selected a spot on Phillip Creek, about eight miles below Sarasota, when Tampa was his nearest market. He built his home there among the oaks and palms, and cleared and planted his citrus groves, and twenty-eight years ago he started in with bees. He has made them a specialty since that time.

In 1910, with 64 colonies, spring count, Mr. Drumwright harvested 400 gallons of extracted honey; 800 pounds of comb honey in sections, and 80 pounds of wax.

Mr. Drumwright is now about 77 years old, and very rugged for one of his years. He says that he has seen hardly a sick day since going to Florida.

No. 1 shows his old home where he reared his family, who are now all married and gone from home. The wife of his joys and younger days has been called to the other world, and now he is left with his bees for companions. The old place was too large

Home of W. J. Drumwright, near Sarasota, Fla.

for his needs, so at the time of our visit we found him moving on up the creek about half a mile. He had sold the old place. The bees were then nearly all transferred to the new locality, and we noted that they were in modern hives, painted white and fresh, and systematically set in regular order.

The new place is a twelve-acre tract with a nice young grove just coming into bearing. The honey-house was built, and at the time of our visit the foundation for the home of the faithful horse was being laid, and the house was to follow.

No. 2 shows a portion of the creek and the honey-house, so built that loading and unloading from the launch could be done with ease. The apiary is located just beyond the honey-house.

No. 3 shows a portion of the apiary with Mr. Drumwright sitting on one of the hives. A small portion of the creek is visible through the palms.

The honey-house on the creek.

Mr. Drumwright in his apiary.

Mr. Drumwright himself, his horse, and his bees, seemed to be the sole occupants of the place. May they live many more years to enjoy their work together.

Philo, Ill.

HOW I BECAME INTERESTED IN BEES

BY BRYAN STRUBE

One morning in May, 1912, as I was passing a schoolhouse I saw something hanging on a limb. A terrible humming sound met my ear. I knew then that it must be bees, although I had never seen so many bees before. I had heard my father talk about them, however, but he had never kept any since I could remember. I hurried home to tell my father. He took a barrel and put in two cross-pieces about six inches from the top, in order to keep the combs from falling. As soon as he looked at the bees he said that they were Italians, and that it was the largest swarm he had ever seen. We sawed off the limb and let it down to the ground easily, a distance of about fifteen feet. We set the barrel over it, and drummed on it until they started in. We then went home to wait until evening before trying to move the bees. After dark we started, taking with us a sheet and a tub. We found that the bees were all in the barrel. We spread the sheet over the tub, set the barrel down in the tub, and tied it up

like a washing of clothes, then put the barrel in the buggy and carried the bees home safely, a distance of about a mile. The next morning they were flying around, and soon began to work in their new home.

Later I ordered two Danzenbaker hives. We transferred them about the middle of August. We took about a gallon and a half of honey from the old barrel. In transferring them they swarmed out on two different limbs. We hived them in two hives. In half an hour they were all in one hive. We then supposed there was but one queen. They filled the brood-chamber and made four sections of surplus.

Ever since I have been reading all I could get on bees. I am sixteen years old, and think that beekeeping for pleasure, profit, and recreation is hard to beat.

Oak Grove, Ky.

HIVE-PLIERS

A New Tool which Saves 25 per cent of Stings and Does 25 per cent More Work

BY JOSEPH GRAY

A good laugh does no one harm, and I surely had a good one at the idea of using "sugar-tongs," yet 25 per cent less stings and 25 per cent more work caused me to change my views. So from jest I turned to earnest consideration of their use, and at

Joseph Gray's combined hive-tool, frame, tongs, pry, scraper, etc.

last produced the tool shown in one of the illustrations. I have, however, given it the more dignified name of "hive-pliers."

The one thing that arrested my attention most was the firm grasp of a comb single-handed, leaving the left hand free to use the smoker, bee-brush, etc. The frames are pried apart, then grasped with the pliers,

one hand only being required to handle them, allowing the free hand full use of the smoker. When using the brush, the comb is grasped by the pliers, dropped on the front of the super sufficient to jar off the bulk of the bees, the remainder being brushed off. These tools are not laid down, hence the gain in time.

During a rush of honey the comb is just pulled over the edge of the super, and the bees brushed off.

The pry forces the nut and bolt to fasten the two jaws together, the reverse-nut end being used for a hammer.

It is self-evident that the pliers save stings. The hands do not come in such close contact with the bees; yet greater is their importance and value in handling diseased colonies. The hands do not touch the comb, only the plier jaws, and these are easily disinfected by burying them in the hot barrel of the smoker.

The first use of the pliers is awkward because one wants to lay them down and use his fingers; but after one thousand frames have been handled by them the experienced apiarist will have learned their use and their value.

Wasco, Cal.

[Hive-pliers or tongs have been suggested by a number of beekeepers, several of the suggestions having appeared in these columns before; but extensive producers

The tool in operation.

usually do not use them, for the reason that they can get along just as well (or better) by using their fingers alone.

Another idea for frame-pliers, sent us by Wm. Grams, of Sturgis, S. D., is shown herewith. Perhaps the latter tool permits of a rather firmer grip on the top-bar, with less tendency of the frame to tip if not grasped exactly in the center.—Ed.]

BEEKEEPING A FAVORITE SPORT

BY HENRY A. SHAEFER

Keeping a few colonies of bees is my favorite sport. I have hunted, fished, played ball, and used a camera. I soon tired of all these, but not so with my bees.

My father is a farmer, and I work on his farm. I care for my bees at noon, and nail up frames and get supers ready in the evening. We live in a rather hilly country where white clover is the principal honey-plant. It is everywhere, and the honey-flow begins about June 10, and usually ends the latter part of July.

The first half-hour that I spent with the bees was a very pleasant one. I had bought a colony of bees during fruit bloom, when it happened that the weather was too cold for the bees to fly. I could hardly restrain my impatience until a warm day came. When it did come I put on my home-made veil (my bee supplies had not come yet), and without smoker or gloves I went to open the hive. I expected to get stung many times before I closed it again, but not a bee dared to be so forward.

I looked for the queen, for I wanted to see if all the talk about her being so large

was true. Three or four times I thought that I had her, only to find that it was a worker distended with honey. It would go into a cell with honey in, and I thought that surely a queen would not lay an egg in a cell half full of honey. At last I found the queen. She was much larger than the bees I had mistaken for her. I took the frame with the queen on it and proudly showed her to the folks, then took the frame back to the hive and carefully closed it, satisfied that I had seen a queen bee.

Every time after that, when I looked into the hive I saw or learned something new. That was and still is my pleasure. The work connected with keeping a few colonies is light, pleasant, and also different from all other work on the farm.

Colfax, Wis.

HONORABLE O. C. SKINNER

BY WESLEY FOSTER

The keeping of bees attracts in all probability more people in varied walks of life than any other line of work with perhaps the exception of poultry-raising and farming. The latter rural pursuits have drawn many business and professional men to their ranks from the city during the past few years.

But bee culture embraces in its list of devotees people from all ranks of life—men, women, and children. Editors and newspaper men generally seem to be drawn toward beekeeping because, no doubt, of the opportunity for outdoor work, without the physical demands that many phases of farming require.

Mr. Skinner is an old newspaper man, who is now a member of the Colorado legislature, and a beekeeper on the side. He owns something like 200 colonies of bees that he has leased to another party. But 20 colonies placed on the roof of a shed at the rear of his home place in Montrose are cared for by himself. I am showing a picture of this shed-roof apiary. Mr. Skinner tells me it is a great improvement over placing the hives on the ground, because of the greater safety to passersby. The disadvantage is that, when walking on the shed roof, all the hives are jarred more or less, which angers the bees. But the flight of the bees being above that of traffic on the street more than balances this disadvantage.

During the spring of 1911 I met Mr. Skinner for the first time. I asked him to introduce a bill in the House relative to apiary protection which had been drawn up by the committee on legislation of the Col-

Shed-roof apiary of Hon. O. C. Skinner, Montrose, Col. Mr. Skinner is speaker of the Colorado House of Representatives in the 19th General Assembly. Robert E. Foster and E. D. Nichols are standing by the ladder. Mr. Skinner is very indistinctly shown close to the barn roof.

S. A. Niver's arrangement for heating honey as it runs from the extractor so that it may be easily strained through cheese-cloth.

orado State Beekeepers' Association. This law passed the Houses, and was signed by the Governor, who, however, cut the appropriation down two-thirds.

Mr. Skinner is a small man, but correspondingly active. He is reputed to be a progressive among progressives, and has lived up to the name pretty well. The bee-men could not hope for a better helper in the legislature in securing recognition for the beekeeping industry of Colorado.

At our 1912 spring convention in Montrose, Mr. Skinner gave us many valuable points on the proper methods of procedure in order to secure apicultural legislation. We used his suggestions this winter. He is a very "likable" man.

Boulder, Col.

A DEVICE FOR STRAINING HONEY AT THE TIME IT IS EXTRACTED

BY S. A. NIVER

I was interested in the April issue of *GLEANINGS* to note that the extracted-honey producers are waking up to the need of some way to strain honey through a cloth fine enough to make it fit for table use. As it comes from the extractor, it is too thick to strain without heating. If run into the five-gallon cans, and the cans set in hot water, part of the honey gets too hot; and, besides, that takes a lot of work and bother, so they let it go, as a general rule.

Then the salesman who repacks for the retail trade has all that to do, and dislikes it, for he must carry quite an outfit, which

must be taken from town to town. He must find a room suitable to work in, spend his time heating, straining, and bottling, all of which means extra cost to the consumer.

Now that I have "reformed," and quit the road work and gone back to my first love (producing extracted honey), my thought naturally turned to some kind of invention that would heat the honey as it left the extractor sufficiently to strain through ten-cent cheese-cloth. I enclose a picture of the device we made for that purpose, and I will only say that it "gits thar," even with our California honey, which the editor has had some experience with in past years.

It consists of a tank or trough 8 feet long, 6 inches high, 8 inches wide, full of water, with two conductor pipes 3 inches wide by 2 inches deep, placed inside, entering the end under the extractor faucet an inch from the top, leaving the end next to the storage-tank an inch from the bottom.

This incline of the pipes, running through 8 feet of hot water, allows the honey to heat until it is thin enough; and as soon as it is thin enough, and not before, it hikes along to the strainer, which is placed above the storage-tank. The two oil-burners will heat the water in the trough in a few minutes; then we turn one burner out entirely, and turn the flame to half speed in the other. The water is then about right to keep the honey out of our way, even when two "lightning operators" are on the job. I had to take the device out of the basement, where it is suspended from the ceiling (as we extract on a floor above), for the light

was bad for photographing; but it is so simple that I presume all will see through the scheme easily.

Allow me, Mr. Editor, to call your attention to a mistake or two in your recent editorial comments.

You said, "If not mistaken, Morton invented the telescope swarm-catcher." Nope! "I seed it first." Then you think that Canuck, Holtermann, has the biggest extractor. Nit! only 12 frames. Our merry-go-round throws 16 at a time, reverses like a Cowan, and I can take it to pieces by taking out a few bolts, screws, turn-buckles, and unhooking wires; nest the whole thing into a small space, take it to an outyard, and set it up again.

This county is three times as large as the whole State of Rhode Island, and contains (so they say) 360 beekeepers. They elected me president of their beekeepers' club, but I have met only 6 of those 360 so far. Jamesburg, Cal.

HOW TWO SWARMS OF BEES WERE CARRIED HOME

BY J. W. STINE

I am enclosing a picture of "a good catch" in the way of two swarms which I captured five miles east of Salem while out on an inspection tour. One swarm is in the nail-keg in the seat by my side, and the other I put in a sack and hung it on the side of the buggy. Both swarms are doing fine work in the supers now. They were captured the first week in June. I thought possibly this might be a new way of carrying bees.

Salem, Iowa.

Carrying two swarms, one in a keg and the other in a sack.

WIRE CLOTH AS A SUBSTITUTE FOR WOOD IN BEE-ESCAPE BOARDS

BY ARTHUR F. HODGSON

During the past season I did considerable experimenting with the bee-escape boards with gratifying success. I think that the result of these experiments would be of

value, especially to large producers of extracted honey. So far as I know, bee-escape boards have been made of wood, the idea being to make a complete separation (except one way through the bee-escape) between the super or supers to be removed and the hive below.

In queen-rearing operations I have noticed the peculiar effect of wire cloth as a partial separation between bees, and this led me to construct a bee-escape board entirely of this material (except for the necessary rim and cross-piece containing the bee-escapes). In a twelve-frame hive I think that the two escapes are a decided advantage.

The enclosed drawing will illustrate the idea. The advantages are that the supers are very rapidly freed from bees, and the deserted combs are not shut off from the heat of the hive. In cool weather this is a decided advantage where combs are to be extracted, and in hot weather it is equally advantageous, as the bees do not feel their contracted quarters as much, considerable heat being taken up by the beeless combs above.

It may be argued that bees separated by wire cloth would pass honey through to their fellows below (even during the few hours there are bees on both sides of the

A GLIMPSE OF OUR DASHEENS AT MEDINA.

The above picture was taken about ten days ago; and to-day, July 30, owing to a very warm spell of weather, accompanied with abundant summer showers, they are almost twice as high; in fact, some of them, if they keep on at this rate, will soon be as high as my head; and the Evergreen sweet corn, right back of the dasheens, is all tasseled out and higher than I can reach. In fact, it is about the finest-looking sweet corn I ever saw. Do you catch on? It is the heavy mulching of stable manure that was put around the dasheens. You can see the fragments of cornstalks in the manure that were used for bedding. You can just get a glimpse of the potatoes further on at the end of the dasheen rows. They not only cover the ground, but some of the vines stretch up higher than my head, although early potatoes. You see the potatoes, Hubbard squashes, and every thing else, "got wind" of the generous feed, and commenced sending out their white rootlets all over into the dasheen patch to get "inspiration." The Solomon's Island gourd or "guado bean," in the middle of the row does not show in the picture; but it would show if taken to-day. It grew about a foot and a half while I was absent in Michigan. A letter just received from my nearest neighbor, C. L. Harrison, reads as follows: "Some of my dasheen is 62 inches high, and the leaves are 26 inches long, 21½ inches wide. I have used some of the small shoots for greens. They are excellent now, July 24. —C. L. HARRISON, Bradentown, Fla."

screen), and thus deplete the combs. After careful observation I failed to notice such a result. My experience goes to show that, if honey is passed through the screen, it is up rather than down. For example, a super fitted with wire-cloth bottom (nuclei for queen-rearing) placed above a strong colony will become clogged with honey from the colony below.

I feel quite confident that, with these rapid escape-boards and my eight-frame power extractor, I can handle alone a probable ten-ton crop this season.

In using these bee-escapes there is no back-aching job shaking and brushing individual combs to free them from bees with the consequent killing and injuring of hundreds of the season's best workers, to say

nothing of the return in stings, and the danger of robbing is reduced to a minimum.

After carefully trying frames with both one and two escapes I am satisfied that there is an advantage (in length of time required) with the frame having two escapes; but this advantage is not important as regards freeing the super of bees. However, when I considered the small extra cost with two escapes it seemed practical to use them; for if, for any reason, one did not operate, the other would. I have never had a Porter escape that did not work beautifully; but I do not wish to take any unnecessary chances confining bees, as confined bees will very rapidly raise the temperature, and this would be disastrous, besides not accomplishing the desired results.

As for the time required, I find that, at the close of the honey-flow, when combs are almost capped, that 24 hours is quite practical. I have put the escapes on early in the morning and found the combs free of bees by evening. As a colony requires seven or eight hours to realize its queenlessness, just so a few hours must elapse before the bees in the super feel their separation. Then the escape works rapidly.

The peculiar adaptation of the screen occurred to me while using a screen frame in connection with cell-getting. I advise the use of galvanized wire cloth on account of its durability.

To give you what I consider the supreme test of this wire-cloth-escape frame, please note: Through some carelessness in manipulating, a queen had possession of two twelve-frame supers in a powerful colony; and as I did not wish to take the time to shake the bees off the combs, and thinking it would be a most rigid test, I put an escape frame in the place of the queen-excluder. Thirty-six hours later I found the queen among a lot of newly hatched workers, and, of course, the drones. I have fifty of these escape frames in use, and I intend making fifty more for next season. I am running 225 colonies, twelve-frame Langstroth hives, entirely for extracted honey.

Jarvis, Ont., Canada.

[See editorial.—ED.]

BUILDING COMBS OUTSIDE OF THE HIVE

BY A. I. ROOT

One of our men who has been out buying honey reports that he found a beekeeper near Columbus Grove, Putnam Co., Ohio, who had over 100 colonies; but he was so "busy with something else" that he had not had time to look after his bees, and the result was they filled all their supers, then clustered outside of the hive, and there built combs and stored honey. The well-filled and capped sections had been left on the hive until they were so travel-stained that the honey was any thing but first-class.

The above incident reminds me of something that happened years ago. A beekeeper with toward a hundred colonies lived three or four miles from Medina. I sold him some modern hives and fixtures, including an extractor; and one season when we were having our great flood of honey I thought I would run over and see what Mr. Pratt was doing. He had not used the extractor at all, although his hives and upper stories were crammed full of honey. He gave as an excuse that his farmwork

was so crowding that he had not had time to "fuss with bees." I asked him what farmwork. He said his corn had to be cultivated. I told him the honey he had lost was worth twice over the produce of his whole cornfield, even if he had a big crop. He could not believe it. Then I showed him what we had extracted from about the same number of hives. Finally he said, "Why, would you advise me to let the cornfield grow up to weeds?"

"Certainly," said I.

"Why, what would the neighbors think and say?"

"Mr. Pratt, I would not care a cent what the neighbors say; and, besides, when those same neighbors saw you taking a couple of tons of beautiful honey they might not say any very bad things after all."

The moral to the above is, what is the use of being a beekeeper if you do not "have your dish right side up when it rains porridge"?

STRAY SWARMS SHOULD BE HIVED ON STARTERS

Danger of Foul Brood

BY A. H. SNOWBERGER

I wish to give a word of caution to beekeepers about a matter that has given me much concern and uneasiness during the last few months; and that is, hiving stray swarms.

Late last season a very small stray swarm clustered on a neighbor's hay-loader while he was at the barn unloading hay. I was sent for, post haste. I was glad to have the bees, as my apiary was much reduced by the previous winter's loss. There was not over a quart of bees, and I supposed it was a very late after-swarm with a virgin queen. I hived them on empty combs, and gave them a comb of hatching brood; but I soon found that they had a laying queen and not a virgin. By feeding and giving another comb of brood later, I built them up into a fair-sized colony, and wintered them; but as soon as they commenced brood-rearing in the spring I noticed something wrong with the brood. I kept them under observation, thinking that they would soon be all right. But instead, they got worse.

I had never seen foul brood; but from descriptions I had read I diagnosed it as foul brood, and a bad case at that. The queen seemed to be a moderately prolific layer; but so much brood died that the increase was slow. Finally I shook the bees into a clean hive, having only half-inch starters, and burned their combs, frames, and brood, and disinfected the hive. At the

same time, I sent a sample of their brood to the Bureau of Entomology, Washington, and soon had an answer from Dr. Phillips, stating that the trouble was American foul brood. He also reported the case to our State Entomologist at Indianapolis, who immediately wrote to me for further particulars. I answered at once, and arrangements were made for an inspector to call on me soon. The inspector made a thorough examination of my apiary of 37 colonies, but could find no foul brood. Even the colony that had been infected he pronounced all right, but said they undoubtedly must have had it, or Dr. Phillips would not have said so after seeing the sample. He gave me a clean bill of health.

I now see danger in having these stray swarms, although I hived three this season which are doing well. If I hive any more I think I will hive them on narrow starters instead of empty combs, then the honey they carry with them will be consumed before they have any brood to feed.

This swarm that I hived last season, and that caused all my trouble, was evidently not an after-swarm, but an old colony so reduced by foul brood that they had deserted their old home, and I hived them to my disadvantage. There are but few bees kept in the neighborhood, and there is no disease among them, so far as I know. The infected bees might have come from a tree in the woods. I was fortunate in discovering the trouble so soon.

Huntington, Ind.

HOW I CHOOSE A BREEDER

BY MAJOR SHALLARD

I was at one of my branch farms lately, where they were extracting. My son asked me to choose a queen to breed from, as he wanted to raise some new queens to replace some mongrels. I had no time to go through any hives, as I had to get away to extract at another farm; but I walked through and chose half a dozen by external signs.

The first two I came to were hanging out. I passed them by, as bees that hang out, in my opinion, are no good. I came to a four-story hive. This looked good because the bees on this farm had only combs they could occupy; and where most of the hives were two and three story, the possession of four showed honey-gathering qualities. I then had a look at the bees at the flight-hole.

They were all evenly marked with three bands. They had a fair number of bees fanning, and they were working steadily. What I mean is that there was a steady stream of

bees going in and out. Some bees make a great show at the flight-hole. They fly about a lot, hover over the flight-board before they alight, and fuss about on coming out before they finally leave for the fields. These bees were not doing that. They flew straight at the flight-hole, dropped on the board, and ran right in. The bees that fuss a lot never get much honey—at least that is my experience.

Having satisfied myself that the queen was pure, and that her bees were good workers, the next point was how much honey they had. I put my hand under the back of the bottom-board and tipped the hive. It required an effort to raise it at all, and it was apparently full of honey. I picked out five more hives with the same characteristics. They were all four-story hives. I said to my son, "Go through these six hives and pick out the one with the minimum amount of honey and the maximum amount of brood in the bottom story. Choose a queen that is large and long. It does not matter if she is a bit black toward the tail; but the black must be solid, and gradually merge into the yellow, or the yellow into the black, whichever way you like to put it; but there must be no suspicion of any black ring. She should lay a good plump egg, and all at the same angle, or as nearly as possible, and the brood should be in solid sheets. The bottom-board should be clean; and if she has these other qualities it will be; and, above all, her bees *must* be good honey-gatherers. Without the latter qualifications all the others go for naught."

In comparing these six queens one will show more of these desirable qualities than the others, and that is the one, so far as can be told at this stage, to breed from.

The next step is to breed from her, and see if she reproduces herself in appearance and honey-gathering qualities in her daughters. If she passes the second test she is good enough to breed from until another queen is found which has all her good qualities, and will get more honey.

South Woodburn, N. S. W., Australia.

When to Introduce Virgin Queens

With reference to waiting three days after taking a laying queen from a mating-box before giving a cell or virgin queen, as advocated on p. 466, July 1, I would say that I put in virgin queens immediately after taking out the laying queens. I use the smoke plan. I noticed one that I introduced July 5, at three o'clock. I examined them at four o'clock, and she had mated in one hour after I had introduced her.

I have tried the smoke plan on requeening strong colonies, but I do not have good success.

Brook Park, Minn., July 11. HARRY BELL.

Heads of Grain from Different Fields

How doth the little busy bee
Delight to bark and bite,
Making honey all the day
To eat it up at night!

Trouble from Mating-nuclei Swarming Out

I want to know how to keep my nuclei from swarming out and leaving their hive. They will leave honey, young larvae, eggs, and hatching bees, and swarm out. My honey crop is almost an entire failure this year.

Jellico, Tenn., July 14.

CURD WALKER.

[We could answer you a little more satisfactorily if we knew what size or kind of nuclei you are using. If you are using the small Pratt baby nuclei you will have considerable difficulty about their swarming out in spite of any thing you can do. If, however, you use the larger size, the twin-mating nuclei, you will have comparatively little trouble providing you put enough bees in each side. The little combs should be well covered with bees; and in order to make this start it is better to get the bees from some outside location. Shake them into a large box; then dip them up by dipperfuls and pour them into the boxes. If you keep these bees strong enough and the queen long enough so that they can keep the frames filled with brood there will be very little swarming out. At certain times, however, we advise the use of perforated zinc with which the nuclei are supplied. Queens must not be kept longer than enough to lay eggs in the frames, or there will be danger of the bees swarming out.]

If, on the other hand, you are using the larger nuclei, employing standard frames, there should be no trouble about their swarming out. In any case, you will, of course, recognize the importance of keeping nuclei supplied with food. If they do not have honey or stores in their combs they should be fed of course.—ED.]

Why the Queens Died in the Cages

Five queens were bought of a New Jersey breeder and mailed about 20 miles on July 4. On the 5th at 9 o'clock the queens were killed in five colonies to make room for the new stock, and one queen-cage placed in each just below the top-bar with the combs squeezed against the cage to hold it in place with the wire-cloth side down and the thin cardboard removed from the candy end. At 3 o'clock P. M. on the 7th an examination showed the queen and all the bees dead in four of the cages, and the fifth apparently all right except that the candy had not been eaten out. A hole was punched in the candy, and the queen released and accepted. The candy was hardly touched in the four cages. No bees were dead in the fifth cage. The queen candy seemed a little dry, but not enough to make it seem impossible for the bees to use it without difficulty. The breeder says all were treated alike. Have you any clue to the trouble?

E. G. CARE, Bee Inspector.

New Egypt, N. J., July 8.

[There are two causes that might account for the death of the queens. One is the kind of wire-cloth used on the cages, and the other the condition of the candy. Referring to the first mentioned, bees are sometimes poisoned by the paint used on the cloth. If it is green we have known of instances where the queens have died. But usually they will arrive in rather bad condition. It is hard to explain why the bees should arrive in fair order, and then die after they were introduced. Taking every thing into consideration, it is our opinion that the real cause was the condition of the candy—that is to say, it was too dry. It was moist enough to get the bees through to their destination, but the bees and queens were probably in a weakened condition at the time they were introduced. The dryness of the candy did not enable

them to survive long. The condition of the candy may be explained by saying that four of the cages had poor candy while the one cage had candy that was a little more moist. The great problem of sending queens by mail is getting the candy just right—not too sticky or moist, and not too dry on the other hand. You state that the candy seemed a little dry, but you think not enough to make it impossible for the bees to appropriate it. Our opinion is that, if you will take these cages where the bees died and put some fresh bees in them, you will find that they will not live more than 24 or 48 hours at the most. If you will put a like number of bees in the other cage where the queen did not die we think you will find a difference in results.—ED.]

Can we get Alfalfa Growers to Cut their Alfalfa Later?

How am I to persuade the people of this section to cut their alfalfa at the right stage? They cut it, to my notion, before it goes to bloom. There is a fine future at this place, providing I can get them to cut it at the right stage. I never in all of my life saw the like of wild bees on the mountain sides. This is what they call Round Valley, containing about 10,000 acres; and as I am only a beginner I should like advice on the subject.

Covelo, Cal., July 5.

F. F. TURNER.

[We suggest that you correspond with Dr. A. J. Cook, Horticultural Commissioner, Sacramento, Cal. He might be able to advise you on this matter. We might say, however, that there has been a tendency on the part of alfalfa-growers to cut their alfalfa just about or a little before it comes into bloom. Some of them have asserted that it makes a little better quality of hay. On the other hand, we have heard that statement contradicted by those who claim to know; but this is, nevertheless, the fact, that the alfalfa-growers are a little behind on their schedule anyhow in cutting their hay, and in most cases they are not able to cut it until it is well into bloom.]

Generally speaking it would be pretty hard for a beekeeper to convince an alfalfa-grower that it would be to his advantage to cut his hay a little later in order to accommodate him, the beekeeper. It looks too much like a case of an ax to grind. If, however, you can get hold of some literature that would show that this early cutting is a mistake it will help materially.—ED.]

Experiences with Bees in a City Apiary

Owing to the comparatively mild winter of 1912 the bees of my suburban apiary came through unusually strong, with no loss, and as pollen was carried in as early as March 12, colonies were soon filled to overflowing with bees. Heretofore I had run exclusively for extracted honey; and in order to give more room it has been my custom, in adding another story, to put in two frames of brood and fill out with empty combs. This spring, however, I had an exceptionally strong colony almost filling two stories; and as it was necessary to add a third one I decided to deviate from my usual custom in giving more storage room. I accordingly prepared a third story and placed it between the other two.

What I most wanted to avoid (swarming) turned out just the other way. I reasoned that the queen now had plenty of room for laying; also that there was sufficient room for storage; but it seems that the bees in that upper story, having been removed from their companions by having a full-depth super placed beneath them concluded they were queenless. They promptly started a fine batch of queen-cells before I was aware what they were up to, and cast a monster swarm. While they were clustered I cut out every queen-cell and shook the bees from every comb, and then returned the bees to their

hive. Hereafter I think I will adhere to my old methods of tiering up.

I run exclusively for extracted honey; however, I tried one hive for comb honey this spring, but with disappointing results. Just before locust bloom I put a super of sections and bait combs on this colony; and as they had every available cell in the brood-chamber full of brood and honey I concluded it was in ideal shape to work in the sections. They started to draw out the foundation in good shape, and then promptly swarmed. As the queen was clipped they naturally returned; but a few days later she disappeared, and now the bees are starting a second batch of fine peanut-sized cells. Such proceedings disgust me with the production of comb honey, and I think this excessive swarming is the chief reason why so many prefer to produce only extracted. As I receive 20 cts. per lb. for the latter it would scarcely pay me to bother with comb honey.

Several months ago I purchased a straw skep, and am having lots of fun with it. I built up a nucleus until it was pretty strong, and then made it swarm, hiving the bees in the skep. They are filling it with comb in great shape, and this old-fashioned hive of by-gone days is a subject of interest to all who visit my home.

Cincinnati, O., June 4.

ALBIN PLATZ.

To Get Rid of Ants

On page 118 of the A B C and X Y Z of Bee Culture you show a method of piling up honey-supers filled with honey to prevent getting sour. How do you manage to keep out the large black ants found in the honey-house? As soon as I put a filled super in the honey-house I am sure to get at least five or six large black ants in there; and unless I pile the supers tightly on top of each other, and something almost air-tight (wire screening is no good) on top of that, the ants get in. They then manage to perforate the comb (only here and there) enough so they leak out, so I can not sell them as perfect ones. What would you advise?

Butler, N. J.

MRS. A. HENDERSON.

[If you are troubled with ants of any sort the plan mentioned would not work. The first thing to do is to locate the ants' nests wherever they may be. If they can be found, pour about half a pint of bisulphide of carbon into a hole made in the center of each nest with a crowbar. After pouring in the liquid stop the hole up with earth and you will find shortly after that the entire nest, eggs and all, will be destroyed. If you are unable to locate the ants' nests you can still employ the same method described in GLEANINGS by placing the pile of supers crosswise upon a board or table. The table legs should stand in tin cans of water or grease. For this purpose the table should be low down and large enough to take up several tiers of supers, providing you have very much comb honey to pile up in this way.—ED.]

Bees Dying Just Before They Hatch

Gentlemen:—Yours of the 16th is received with the booklet, "Bee Diseases," which I have read carefully, but find nothing that corresponds exactly with my trouble, as the bees appear to die when three-fourths developed, as you will see by enclosed, while many that mature and cut out of cell apparently perfect, can not fly, are undersized, and weak. There is no odor, nor sign of paralysis.

Wilkinsburg, Pa.

W. D. KEYES.

[The cage of dead bees has been received. The bees show very clearly that they are undeveloped young bees that have been picked out of cells of combs. It would be my opinion that this brood had been chilled or overheated at some time. A comb that is allowed to stand in the sun for a very short time on a hot day would become so hot that it would kill the brood, or at least a large part of it. In the same way, a cold chilling wind or a frosty atmos-

phere will destroy brood, resulting in young bees hatching out that are imperfect or dead. One is apt to gather the impression that it is pickled brood, foul brood, or some other brood disease. Brood dead from these diseases does not look like the specimens of dead bees received. In fact, they never attack bees almost ready to hatch. Brood may die in this way that has never been exposed to the sun. Sometimes the entrance is closed up temporarily, allowing the colony to become so heated that the brood will be affected.—ED.]

A Handy Hive-scraper

I am sending you a description of a hive-scraper that I have had in use for about 25 years. It is nearly the shape of a letter A, only the top of the scraper is $3\frac{1}{2}$ inches wide, 5 inches each side, and $7\frac{1}{2}$ across the bottom. When using the scraper I hold the top edge with one or both hands. This

scraper is made from a piece of old crosscut saw. The long side or bottom is always kept filed off square. This makes a good implement for scraping off propolis and other refuse about the hive.

Lakeville, Ind.

C. A. BUNCH.

Learning by Costly Experience

When I first began beekeeping I knew in a vague way that a queen, drones, and workers compose a swarm, and that the workers gather the honey. That was practically all I did know until I began to read up on the subject of bees.

I had a colony of bees (in a store box) which I had caught the previous summer, so I transferred them into two home-made hives which I bought. I took out about 75 lbs. of honey. I bought two Italian queens, but lost one in introduction, and the other in the spring through robbing. Those bees were very cross; but I think now that they had good reason to be so, as a man who has never seen bees handled has to learn a good deal by experience, no matter how much he may have read.

Well, I bought two more colonies from a farmer, and became accustomed to being stung quite regularly by them. I secured a fair amount of honey also. Then when the craze for Caucasians came I got some queens and introduced with very good success in the early part of the season, but lost two out of three in the fall when I thought I knew all about introducing. Those bees did very well, and I raised a few queens by the nucleus plan, but got most of them misnamed, and could distinguish them from the blacks only by handling. I had by this time seen drone-laying queens, and had laying workers.

About four years ago I bought five colonies cheap from a neighbor, and transferred in the early spring to Danzenbaker frames. I got a fair crop of clover and milkweed honey; but in August I noticed something wrong. The bees were not working well, were greatly reduced in numbers, and there was a decidedly sour smell on opening a hive. So I began buying Italian queens, destroyed some of the worst combs, and doubled up some weak ones. I lost two

in the winter, and started with six good colonies in the spring with hardly a sign of foul brood in the hive. Although in this county a good many small beekeepers have lost all their bees, I have not noticed a sign of disease in two years.

I have never seen an expert handle bees, nor have I done any thing original; but I have transferred bees for men who had kept them long before I thought of it. I have raised some good queens; have divided bees, and have introduced queens for beginners. I have tried to increase the interest in beekeeping among the small beekeepers in this neighborhood.

Waynefield, Pa., Feb. 17. WM. ROSEMERGEY.

The Striking Appearance of the Cocoons in Combs Melted by the Sun's Heat

I have recently had some old brood-comb exposed to the sun in such a manner that it has become disintegrated in such a way as to be very interesting. Since seeing this I have wondered if it is generally known how that each individual cell is made complete and united with the adjoining cells, and also to the central walls, by a substance of a different consistency from that of which they are composed. If information along these lines, together with photographs which might be taken illustrating such structure, would be of interest to your readers, I should be glad to furnish such.

Duluth, Minn., July 21. S. GEO. STEVENS.

[What you describe in your letter has been observed by all those who melt their combs in solar wax-extractors. The same condition will very often appear when combs are melted by artificial heat in hot water. What you observe are the cocoons left by the bees from brood-rearing. When their combs are melted by the sun or in such a way that the structure of the cocoons is not disturbed, the appearance is quite striking and remarkable to one who has never seen any thing like it. There have been numerous photographs of it. Indeed, it is quite a common sight to one who has any thing to do with melting up old combs. New combs when melted up will show nothing of this kind, because there will be no cocoons left as a residue.—Ed.]

Where to Keep Honey

What kind of place is the best to keep honey fresh? What should the temperature be?

New Lenox, Ill., June 26. M. J. SIMMER.

[The best place to keep comb honey is in a warm or hot dry room. A cellar, refrigerator, or cold room is the very worst place. When we say hot dry room we mean a room where the temperature may go up to 80 or 90 degrees in hot weather, and where it will never go below 70 degrees in cold weather. Extracted honey, however, may be kept in a colder room, but it will granulate. If the honey is in bottles it should be kept in a warm dry room the same as comb honey. Otherwise it will granulate, especially if the temperature is inclined to go down to freezing, then go up to ordinary living temperature.—Ed.]

Bees' Turnstile

Please mail me copy of GLEANINGS containing the following clipping, which was printed in Newark, N. J., *Morning Star* July 8, 1913.

Elizabethtown, N. J. ELMER E. GUY.

A novel and ingenious device known as a bee meter, which serves much the same purpose as the turnstile at an amusement park, is in use by a western beekeeper. The bee, in passing through an entrance or exit, deflects a thin delicate spring. To this spring is attached a wire, and the deflection of the spring causes the wire to hook over a tooth on the rim of a paper counting-dial. As the spring returns to its normal position the dial is rotated slight-

ly, and counts one unit. A lug on the unit operates the ten-unit dial, as in the ordinary counting-machine, and this system is continued to include a 1000-unit dial capable of registering 20,000. The spring is so shaped to prevent a bee from going out through an entrance or entering through an exit. This device renders it easy to estimate the activity of a colony, and to determine the number of bees that go out but fail to return.—*Popular Mechanics*.

[The clipping did not appear in GLEANINGS. We doubt very much whether the thing was ever done, although we concede that it would be possible, perhaps, but decidedly improbable. There is such a thing known as a bee-escape. This has two sensitive springs between which the bees pass, but, so far as we know, no recording-device was ever used in connection therewith.—Ed.]

Why a Queen Sometimes Lays in the Sections

My colonies all succumbed but one, and that is the strongest one I have. It is boiling over with bees all the time; but the queen in this colony has been laying eggs up in the sections. The first super I took off had drone brood in some of the sections. The next had bees and a queen-cell. I should like to know the cause of this, and the remedy. This colony has made at least 150 lbs. of honey, which would all have been perfect sections had it not been for this brood. The upper part of the section would be honey and the lower part brood. Twelve of my colonies have averaged 100 lbs. of honey each.

Shelby, Ohio, July 21.

SARA A. KERR.

[As a general rule, in the production of comb honey queens will not lay in the sections. Occasionally, however, we find one that has a tendency to go above. In such cases it is advisable to use a queen-excluder; but while such devices are commonly used in the production of extracted honey they are rarely used in the production of comb.

It sometimes happens that a queen will lay in the sections for the simple reason that there is no drone comb in the brood-nest below. When only starters are used as sections the combs built below will very often and generally be drone. If there are no drone-cells in the brood-nest the queen is quite inclined to go above and lay in these cells. Usually there will be enough drone-cells in the brood-nest to satisfy all reasonable demands of the queen.

Rather than destroy the queen that you have, your better way is to put a perforated zinc honey-board over her next year.—Ed.]

Start in Beekeeping Made by Capture of a Swarm of Bees

One day the last of June, several years ago, a swarm of bees clustered in a tree near our house. Mother saw them and called father and myself. It was the first swarm I had ever seen, and father had never seen a swarm hived. We borrowed from a neighbor an old-style chaff hive, and, putting it in a buggy, we ran it under the swarm—father with his stockings over his pants, a rain-proof coat, a pair of mittens tied over his coat-sleeves, and a veil made of a bag and mosquito-bar. He shook the bees into the top of the hive, and put on the cover.

Father gave me his share of the bees, and a few nights later I set them on the ground and took the buggy away. The bees acted lost for about a day.

The neighbor from whom I had borrowed the hive told me to put a newspaper over the frames, and not to put any sections on, for the bees wouldn't make more than enough to winter them.

In a few days the bees had gnawed the paper full of holes, and were carrying it out. I piled on more paper.

Next I visited an old beekeeper who told me to use oil-cloth instead of paper, and to put on some

sections. He also lent me the A B C of Bee Culture and some copies of GLEANINGS.

After putting on the sections I got about thirty pounds of dark honey. This interested me, and in the spring I bought enough bees so that I had ten good colonies and two nuclei. From these I secured 700 pounds of honey, and increased to 24 colonies. The best colony gave me 130 pounds. We now have about 100 colonies. The best one last year gave 180 pounds of comb honey. I have had a colony of black bees for five years that has never swarmed, and which has made about 100 pounds each season for four years out of the five. The other year this colony made about 80 pounds. This is by far the best average of any colony I have ever owned.

Lottsville, Pa., Feb. 7.

EDWARD CARR.

Bees and Chickens

The frequent articles in GLEANINGS regarding the action of poultry toward bees led me to report my own observations. I have so planned my building for housing a few chickens in the city that my half-dozen colonies of bees can be wintered in the same building. The entrances are placed about 2½ feet from the ground. Although the alighting-boards are higher than a tall fowl can reach, yet several of the young cockerels in some manner acquired the habit of jumping up and catching bees while flying. The hens seemed to pay little attention to the bees, although I observe that a bee flying too near a hen is pretty sure to be caught.

This season I have been troubled with bees attacking chicks only a few days old. They would often fasten themselves in the down upon the wings and back, and would at times keep the mother hen busy picking them off, which she was able to do with great dexterity. In some cases I found the chicks suffering, and on examination I would find stings in the feet. As a last straw before deciding to remove all bees from the building, I found a chick four or five days old in convulsions, and deserted by the mother hen. The chick was determined to tie its neck into a knot, and seemed to be doomed. On opening its mouth, a bee-sting was found in the tip of the tongue. The sting was removed, but the convulsions continued for three or four hours, when the chick completely recovered. I believe that the chick had swallowed a live bee, which, without doubt, was raving about in its crop. I think the experience shows that bees are apt to be worse for chickens than chickens are for bees. Although none of the chicks were killed, I feel sure that several were severely stung.

Ypsilanti, Mich.

F. R. GORTON.

Light-colored Hives Cooler than Dark-colored Ones

I have just read with keen interest the friendly "scrap" between our genial friend Dr. Miller and his alert and keen adversary, the editor; and if the latter will be so kind as to give these few lines space I should like to state a few experiences and observations in my own little apiary of 14 colonies. I have my hives painted in three colors—light gray, dark red, and dark olive green. To-day, June 21, the weather is hot, partly cloudy, and sultry—90 in the shade at 1 P. M. Walking among the hives I notice that the bees in the gray hives are working busily—probably ten bees ventilating on the outside on an average. Those in the red hives seem to feel the heat more, and there are at least twice as many fanning, and as many more walking back and forth on the alighting-boards, doing nothing.

Coming to the dark-green hives I notice about a quart of bees covering the fronts of the hives above the entrance, and several knots of them hanging below the entrances besides. These bees seem to feel the heat the most, and there are several rows of bees extending at least six inches from the entrances, al-

most fanning themselves off their feet in an endeavor to keep their habitation properly ventilated. I also find that the covers of the latter are by far the hottest.

It is evident that our worthy editor is entirely right in maintaining that bees do better in a hive painted white or light gray than those in dark-colored hives, as the latter absorb the heat, while the former repel it. For the same reason light colors in clothing, shoes, etc., are much cooler in hot weather than black. I intend to paint all of my hives white next fall.

Cincinnati, O., June 21.

ALBIN PLATZ

Bees Building Comb to Fences

I had my first experience in taking honey. Having noticed, some days ago, that the boxes were being filled, I removed the super to-day and replaced it with an empty one. Although nearly every box was filled with superb honey I found, much to my chagrin, that the honey in nearly every box was attached to the three-panel fence, and I got only about half a dozen salable boxes. Now I am writing to know what hive I can use to avoid this difficulty. I am contemplating going into the bee business to a small extent, but this, my first experience, is disheartening. Surely there are hives in which honey can be produced without running such risks.

Angola, N. Y., July 21.

C. S. PALMER.

[Occasionally we run across a queen whose bees will build the comb up against the slats and posts of fences, but cases of this kind are not common. You would have no trouble with such a queen by using what is known as the old-style slotted sections and separators. Your difficulty can be avoided, however, to some extent by giving the bees more room while they are filling. In other words, give them an extra super on top while they are filling the lower one. Sometimes it is advisable to put the extra super under while they are working on the upper one. As the season draws to a close, take away the partly filled super and allow the bees to finish up the work in the supers nearly completed.—Ed.]

Bees Confused by the Moving of a House that Stood Close to the Hives

I have my bees in my backyard about 20 feet from the house. I moved the house back to build in front. We began moving the house back without having changed the position of the bees. When we had moved it back about 16 feet we noticed that the air was full of flying bees; but we never thought of any trouble until one of the men was stung.

I knew then that there was something wrong; so I watched them a while and soon found the trouble. I picked up one of the hives and moved it about the same distance from the house that it had been in the first place. The bees all settled down again, so I carried the two other hives to the new location, and in a few minutes the bees were as quiet as ever.

Horse Cave, Ky., May 26.

C. S. RHEA.

Do the Northern bees that have been bred to withstand the winter cold thrive in the far South where they may be busy every month of the year?

Dawes, Ala., July 10.

E. M. DOWNER.

[There is no difference, so far as we know, between Northern and Southern bees. They will work just as well in one locality as another, providing there is honey to be gathered. Some strains of bees, notably the darker ones, it is thought, will stand the cold winters in the North better than the extra-yellow bees from the tropics, but the difference is very slight if any.—Ed.]

Our Homes

A. I. Root

I have been young, and now am old; yet I have not seen the righteous forsaken, nor his seed begging bread.—PSALM 37:25.

His leaf also shall not wither; and whatsoever he doeth shall prosper.—PSALM 1:3.

I want to talk to the younger ones, and perhaps some of the older ones also, in regard to the matter of "good luck." On another page I speak about lucky stones. So many people still continue to believe in that sort of good luck that *over a hundred* testimonials are given. Of course, I do not know whether the testimonials are genuine or not; but I *do* know that quite a number of good people carry senseless things in their pockets or on their watch-fob, to bring good luck. Our older readers, at least, have heard about its being a lucky thing to find a horseshoe. Well, if you have a horse lacking a shoe, and the shoe you find just fits, it may be what is called good luck; and I do not know but it is true that the man who is picking up and saving horseshoes, or any thing else lying around loose, may be more "lucky," as the world expresses it, than the man who lets valuable property and material lie about loose here and there. It has always been my fashion, especially around our own premises, to pick up and put away horseshoes, pieces of iron piping, bits of wire, both iron and insulated copper wire such as the electricians scatter about; and I have a faculty of remembering where I put these things. Pieces of iron wire I hang on the fence near the gate; and then when a bit of wire is needed in an emergency I can almost always lay my hand on it quickly. Such a habit, without question, *brings* good luck.

Years ago, when lotteries were permitted to flourish in our land, there was much said about lucky numbers; and we were told that some people were always lucky in investing in lotteries. My feeling has always been, however, that the person who secures prizes by investing in a lottery is really the unlucky one. Money that comes in that way, or without hard earnest labor, often proves a curse rather than a blessing. Captain Rand, in advertising his lucky pebbles, says that one who has one of those pebbles in his pocket will always prosper, no matter what he invests in or goes into. He does not exactly quote scripture to prove it, but what he states is something like one of the texts I have chosen—"Whatsoever he doeth shall prosper." And, my good friends, both young and old, I am glad to be able to tell you this bright summer morning *how* to be lucky and prosperous in all you undertake. That beautiful first Psalm, which

I have often quoted, and which, it seems to me, must have been written when David was comparatively young, sounds boyish in its bright hopefulness. Now, then, what are we to do and how are we to live so that all our undertakings will be prosperous? May be you had better get your Bible and look over that first Psalm with me. First, you are to keep out of bad company. You are not to walk with them, nor stand still in a bad crowd; and you certainly will not be lucky if you sit down and visit with those who pick at the faults of Christians, and make fun of God's holy word.

Years ago our boy Ernest had a playmate who lived near by. One day his mother heard Ernest using bad words. She asked where he had learned them. When he told her she told him he would have to stop playing with Edson if Edson persisted in such talk. Edson came around pretty soon and asked why Ernest would not come out and play any more. Ernest told him of the trouble; and after a while Edson was induced to give up his bad talk, because he found out that Ernest would go straight home when he used swear words. Later on, an acquaintance of mine was apparently thoroughly converted; he gave up drinking, and promised to lead a new life. But after a time, however, he was seen among his old comrades. When we remonstrated, he replied that it was pretty tough to know that he could not see his old friends, and sit down and talk with them. He said some of them might be made better men. Accordingly he would go into a saloon and sit down and talk with his old boon companions. I hardly need tell you how it turned out. It transpired, as we have it in that first Psalm, that it is exceedingly dangerous to "sit in the seat of the scornful."

The next verse tells us what a man ought to do to be lucky. It says, "His delight is in the law of the Lord." The law of the Lord is this precious book that I am now holding in my hand. And we are further told of this prosperous man that "in his law doth he meditate day and night." There you have it, friends. If you wish to be prosperous, if you are striving for good luck in your undertakings, just make this book your lucky stone. Use it as the iron-clad pledge of the Endeavor Society reads, "I promise to read my Bible every day." Not only are you to read it every day, but you are to make it your constant study "both day and night." If you do this you will eventually grow like a tree "planted by the rivers of water." I thought of it

when Dr. E. F. Phillips told me the dasheens grew in those far-off islands of the sea with their little white roots reaching over into a rivulet of water. "His leaf also shall not wither." How many times we feel blue and troubled when it does not rain, and the leaves of our crops begin to wither and turn yellow! When there is plenty of rain, however, as we have had this season (throughout Ohio and Michigan at least), there is no withering of the foliage. It is like my garden and the beautiful dasheens with their leaves a foot and a half across, on this last day of July, 1913. Then David goes on to say, "The ungodly are not so." They may prosper for a time, but sooner or later they are gone, and their memory is forgotten, "like the chaff which the wind driveth away."

As I come nearer to my 74th birthday, and look back over the record of my friends and acquaintances, those who ridiculed God's holy laws are gone and forgotten. Not so with those who labored for righteousness and the good of humanity. Their memory still lives, and their work goes on. Children brought up in godly homes take up the work of their fathers and mothers, "and their works do follow them."

My good friends, have you a Bible of *your own*? Are you reading and listening to its counsels every day? Have you discovered that, although there may be a great deal in it that you do not as yet understand,

that it shows forth on every page that it is the word of God and not of man? that it holds up the highest type of character of any book in the world. It enjoins righteousness, temperance, and purity, and protests vehemently against selfishness and every thing that is low and ignoble. Are you making that book the book of all books? and is your main delight "in the law of the Lord"?

At Traverse City I was agreeably pleased to find a young friend of mine who had just taken charge of one of the prominent hotels of the town. Owing to the number of travelers who wanted lodging all at once at a late hour, there was difficulty about finding rooms for all. But just as I prepared to retire I had another pleasant surprise in finding a nice substantial Bible with plain clear print on my table. Just inside of the cover was a mention of the Gideon Band of traveling men who had raised the money and taken the trouble to place such a Bible in the sleeping-rooms of every hotel in our land. You may recall the fact that I mentioned a carload that went to Chicago for this purpose. God bless the Gideon Band. If they do not get back the money they have expended in this missionary work they will get back something of more value than money, for they have indeed been "laying up treasures in *heaven*" as well as here on earth.

Notes of Travel

THE OLD "CABIN IN THE WOODS" ONCE MORE.

It is now just about two years since I visited our cabin in the woods on Grand Traverse Bay—the place that figured so largely in our Home papers some ten or twelve years ago. Northern Michigan is a great rendezvous for campers during the hot weather; and when the Ann Arbor railway announced an excursion trip from Toledo to Traverse City and back for only \$5.00, right during the extremely hot weather of the latter part of July, a great lot of people responded. There were something over 500 on the train on the 24th of July.

Our readers may not be aware that the Ann Arbor Railway Co. was progressive enough two years ago to start motor cars twice a day from Toledo, Ohio, to Cadillac, Mich. These motor cars are much like the electric cars, but larger, and they are propelled by a gasoline-engine on each car. They not only have regular stopping-places about a mile apart, but, if I am correct, they stop and take in anybody anywhere who is tired of going on foot. These motor

cars are not only a great convenience to people all along the way, but they enable their steam-drawn cars to run something on the plan of the "limited," stopping only at the larger stations. The motors, you see, pick up passengers and leave them at the regular stopping-places for the steam cars, in the larger towns. Each car contains, besides the engine-room, a smoking-room, and very nice accommodations for 83 people. As they have been in successful operation for two years, they probably will continue.

I was agreeably pleased to see a great improvement in agriculture all along the railway. The sandy soil of Northern Michigan has long been considered a difficult problem, even for the Michigan Experiment Station. On my trip I found greatly improved dwelling-places as well as better crops of corn and potatoes, oats, and sometimes very fair wheat all along the way. When I got above Traverse City, on the shores of Grand Traverse Bay, I found cornfields that not only rivaled our best corn-growing districts in Ohio, but some of

them were even further ahead. It is a little sad, however, to find all over our country that the expert and progressive farmers are in the minority. It is so down in Florida, and it is so all the way from Florida to Ohio, and all through Ohio. Here and there we find men who are able to "do things," and who shoot up ahead of the rest. I have faith to believe, however, that the coming generation are catching on to the state of affairs, and are making better. Surely our agricultural colleges and our experiment stations where boys are taught "sense and science," ought to be producing some satisfactory results by this time.

In times past I have frequently mentioned my friend James Hilbert. Ten years or more ago I began to urge Mr. Hilbert to test alfalfa. In fact, there was a small field of alfalfa between his place and mine; but he had so many different hobbies—strawberries, raspberries, peaches, cherries, etc., that I could not get him interested. On this visit, however, I was most happily surprised to see beautiful green fields of alfalfa growing with surprising vigor—about ten acres in all; and as the fields of it dotted over his farm in different places it was a magnificent sight—at least to me. His first field is now about three years old, and it has given him an enormous amount of feed; and the plants seem to be getting stronger and more vigorous year by year. He succeeded in pulling up a plant, but where it broke off, about three feet down, it was almost the size of one's little finger.

The great secret of alfalfa holding out through protracted drouth is that it sends the vigorous tap-roots far down to permanent moisture. There are some stories to the effect of the roots going down into a well thirty or forty feet. Mr. Hilbert says one great reason why there is not more alfalfa grown in the Grand Traverse region is that the farmers must learn the secret of getting a stand or a "catch," as it is called. The field should be in good fertility, and as free as possible from weeds. In that region seed is usually sown in June or July, and you want the nitrogen bacteria. You may have seen something advertised in the journals called formagen; and they are sending a little bottle of the bacteria-forming material for \$2.00. This is enough for an acre. Now, the Michigan Agricultural College has taken hold of the matter, and issued a pamphlet on alfalfa, agreeing to furnish enough of this material for inoculating soil for 25 cents instead of \$2.00. And that is characteristic, I believe, of the Michigan station. I am in hopes that the experiment stations of other States are doing a like praiseworthy work for the farmers.

Mr. Hilbert bought one lot of alfalfa seed that was, a considerable part of it, sweet-clover seed, and where there was a good stand of alfalfa in full bloom, and forming seed rapidly, there is also a pretty fair stand of sweet clover, about as high as one's head, also in full bloom. Mr. Hilbert says that, although he got something he did not expect and did not order, he is well pleased with the sweet clover. Very likely it will be a great help in getting in the bacteria for the alfalfa, after the sweet clover is gone. He proposes to cut and thrash for seed, both crops at once. While he is not prepared to say that good alfalfa hay entirely cuts out the necessity for grain, he says it comes pretty near it. A progressive neighbor of his, I am told, has *forty acres*, and others are reported as getting the alfalfa fever.

I found a young friend of mine, whose farm joins my own forty acres, sowing alfalfa through his cornfields after the last cultivating. This is something of an experiment, it is true; but it may turn out all right.

They have been having very opportune rains all summer up there, which accounts largely for the general prosperity. The beautiful soil on the sandy hills enables them to grow nicer potatoes up there quicker than we get them here in Ohio, for I found new potatoes at about every place I stopped.

Now for a glimpse of the premises around the cabin in the woods. It had been two years since I set foot on the place, and five or six years since I gave my young fruit-trees any care. What is the result? The peach trees are mostly dead or dying. They would, perhaps, have survived the cold winter of 1911 and '12 had they been properly pruned, mulched, etc. The apple trees, however, are doing fairly well; and a Yellow Transparent tree was so loaded down with fruit that some of the branches were lying in the grass. The apples were just beginning to ripen. It was somewhat a question of what things would survive such neglect. About ten years ago I planted fourteen different kinds of currants—a bush of each kind. Almost every currant-bush lived in spite of grass and weeds, and most of them were bearing fair crops, some of them heavily loaded. A row of asparagus-plants were looking as thrifty, almost, as if they had had cultivation. A widow has the place in charge; but she was so busy with her own farm a good deal of the stuff was never gathered. A grapevine had climbed into a mulberry tree, and some beautiful clusters of grapes were growing side by side with the mulberries. The tame raspberries I

planted had been mostly run out by the native sort. But not so with the blackberries. They had survived, and were bending to the ground with great masses of green fruit.

This is a wonderful region for red raspberries, and I am going to talk a little at length about the red raspberries in Northern Michigan. My good friend J. Palmer, who is also a subscriber to GLEANINGS, has about the prettiest raspberry-farm I ever saw. There are acres of great clumps of Cuthbert raspberries, all just alike; and we arrived there just while a dozen or more boys and girls, men and women, were picking the fruit. When we first drove up I suggested to my friend who was driving that we would find Mr. Palmer sooner if we inquired of "that boy in the cherry tree close by the road;" but when said boy looked up to give us directions, there was a roughish smile on his face; and I could not understand why he should blush until his face took on almost the same color as the cherries until a lady at my side suggested that said *boy* was a *girl* wearing overalls so she could climb around where the cherries were thickest. Now, that is all right, especially if the father or mother were somewhere near by. She was quite young, and any sort of skirts would be more or less a hindrance in climbing among the branches of a cherry tree bending down with ripened fruit. When she comes down out of the tree she no doubt has some sort of skirt to slip on before she goes around among people.

Well, friend Palmer took great pride in showing us over his plantation. He invited us to go out where the berries had not been picked; and, didn't we have a "picnic" that afternoon? Then he showed us a model cherry tree loaded down with the most luscious fruit; and we ate more cherries after we thought we had had plenty of red raspberries. The raspberries on his cultivated ground were beautiful, large, and luscious fruit; and I think he is getting a price that will pay well for all his time and trouble. When I asked him about maintaining such fertility on the ground I used to think was almost "no good," as it is so full of sand and gravel, he pointed to a field of clover, rank, luxuriant, and full of bloom. Turning under clover is the secret. A big swarm of bees that had been hived near the cherry tree also attracted our attention.

While red raspberries are found all over the woods in Northern Michigan, right up around our cabin they were so dead ripe that they rattled down on the forest leaves whenever we touched a bush. Of course, the wild ones are not as good, nor as a rule as large, as the cultivated Cuthberts.

While I am talking about raspberries, let me remark that, as we were approaching the city of Cadillac, I wondered why the train should stop right out in the woods where there was no station. We soon understood it, however, for a dozen or more women and rosy-cheeked girls climbed into the car, each one holding a basket or dishpan heaping full of wild red raspberries. The obliging conductor of the train had carried them out into the wilderness in the morning and stopped to pick them up with their loads of berries about six o'clock in the afternoon. Now just a little more about red raspberries.

Freddie Heimforth, the eighteen-year-old son of the widow who has charge of my place, has three colonies of bees. One of the three has already given *ninety sections* of comb honey, besides sending out a rousing swarm; and as the honey was coming in when I left he will probably get more yet. Well, Freddie picked out a section from the ninety—one that was quite a little travel-stained. The honey was thoroughly ripened. I had finished breakfast, and I thought I did not care for any honey. But he cut out perhaps a quarter of a section. It was so thick it would hardly run, and was a beautiful golden yellow. Now, beside my plate was a bowl full of mush made of cream of wheat. My breakfast was so ample and satisfying that I had not got around to the cream of wheat; but when I tasted that honey, not seeing any bread and butter, I took a spoonful of the mush. Do you remember what Ernest said a while ago about cracked-wheat muffins and nice honey? Well, I just recalled it when I tasted that mush with the honey. A part of a glass of milk that I had left stood near by; and I not only ate all of that honey and drank all of that bowl of milk, but I was so full of enthusiasm for the raspberry honey of Northern Michigan that I felt just like saying it was the very nicest honey I ever tasted. Mrs. Root, however, reminds me that I have said the same thing so many times before that nobody will believe me if I say it again. Did such a big breakfast make me sick? Not a bit.

I kept inquiring all around about that Sunday-school over among the hills that I started thirteen years ago. The people told me it was still going, and that it had been running all these years, winter and summer; but they guessed a good many didn't go of late. So, after my hearty breakfast I started out to invite the people I knew to come to Sunday-school next day. I told them I was going to talk a little while. Well, I told you before about the great hills—the biggest hills, if I am correct, in all

Northern Michigan. In order to get over to that little church down among the hills I was obliged to climb the hills on my own premises. Ten years ago it made me very tired, and I sometimes had to sit down and rest on the top of the big hill. But on this particular Saturday I not only walked up the hill, but I pulled off my cap (my coat was left behind) and *ran* uphill, and I did not mind it a bit. I was so rejoiced that I had *gained* strength and muscle, in spite of the fact that I am just approaching 74, that I shouted praises to God. Nobody was near, for I was off in the wilderness; and I kept climbing up and down hills from one neighbor to another all that Saturday afternoon, and I did not get tired a bit. What is it the good book says that comes in right here?

They that wait upon the Lord shall renew their strength; they shall mount up with wings as eagles; they shall run, and not be weary; and they shall walk, and not faint.

Do you ask me who it is, or what people shall have unusual strength? Let me quote further: "They that wait upon the Lord shall *renew* their strength." And it occurs to me that, if the text did not hit me exactly, it came pretty near it, for I was inviting people right and left to come over to the Sunday-school and the preaching service next day. It was a bright and beautiful Sunday when we gathered around that Bingham church. The first thing that greeted me was a row of sheds for horses and buggies—about the neatest and most comfortable sheds for protecting horses (and perhaps automobiles) from the wintry blasts of Northern Michigan that I ever saw. When I was congratulating the men folks on what they had done to enable people to get out to church on stormy Sundays my good friend Mrs. Wilson, who has been all these years superintendent of the Sunday-school, informed me that the *men* did not build the sheds. I turned to her in astonishment and said, "Why, Mrs. Wilson, if the men folks of this community did not build those comfortable sheds, who did build them?"

"Why," she replied laughingly, "they were built by the ladies' aid society. Of course the men came in and helped after we had started the thing going, as they almost always do."

Her bright animated smile intimated that she had no grievance against the men folks. As the back of the shed was built against the sandy bank it was all cement and cobblestone. After this cement wall was put up, the sand and gravel were banked all around so it would be a very comfortable place on a stormy Sunday, especially when

the sun shone in at the open south side. A flower-bed that I made and planted contained some poppies; but the other plants were mostly gone, from the fact that the good woman who kept it for so many years had been called to her heavenly home. I talked to the Sunday-school about what I have given in Our Homes in this issue.

Speaking about cement walls reminds me that my good friend Hilbert has a lot of hot-beds or cold-frames made entirely of cement, of course with glass sashes on top. In these beds he starts cabbage, cantaloupes, tomatoes, and other stuff to get an early market for Traverse City before anybody else. He was just selling Early Jersey Wakefield cabbages at 8 cts. per lb., because he had the first on the market, and because his cabbage was so much superior to that shipped in from Florida. He set out in the field 1400 hills of choice cantaloupe melons, and they were just setting fair-sized melons. His tomato-plants were loaded with green fruit, some of it big enough to be ripe; and an up-to-date motor truck carries his produce about nine miles to the city. Mr. Wilson, the husband of the good woman who is superintendent of the Sunday-school (and who kept it up winter and summer), has a fine farm of 200 acres. He is a crank on growing apples, and expert in grafting. His cornfields are about the cleanest and handsomest I ever saw; and when I looked over the prettiest kitchen garden interspersed with flowers here and there I asked my young companion, Jimmie Draper, eleven years old, "Why, Jimmie, who took such excellent care of this beautiful garden?"

He replied, "Why, Mr. Root, I think it was my mother and grandmother. My pa does the cultivating, but the women-folks do the rest."

I have told you about some of the crops in that beautiful county of Leelanau, Michigan. But there is one crop I did not mention—at least I did not say much about it. Young Mr. Wilson, whose farm adjoins mine, has three beautiful little girls and a boy. Mr. Draper, a son-in-law of Mrs. Wilson, superintendent, has also three beautiful little girls and a boy. The boy took me through the garden.

When I gave them my talk after Sunday-school I asked them if the Endeavor Society was still kept up. There were many affirmative nods from my smiling audience.

"When do they hold meeting?" I asked.

Somebody replied, "Right after Sunday-school."

Then I concluded I would have to make my talk short. Well, who do you suppose led the Endeavor meeting? Why, a bright

young woman who had a baby in her arms. When she led the meeting she deposited the baby on the floor back of the pulpit, and there he lay during the meeting as contented and happy as could be. I congratulated her on having succeeded so well in shouldering her double responsibility. Oh, if all the married people in our land would care enough for the church and Sunday-school to go and take the baby along, what a blessed thing it would be! and what a grand start it would give that baby to get familiar with the Sunday-school before he is even a scholar! We had an excellent sermon in the evening with a crowded house. The text was, "Bring up a child in the way he should go, and when he is old he will not depart from it."

OBJECTIONABLE FEATURES IN REGARD TO COMING TO FLORIDA IN THE WINTER, ETC.

Mrs. Root has suggested to me several times when I am writing up all the nice things about southern Florida that, to be fair and honest, I should also tell of the objections. One morning we counted up four things that were more or less objectionable in regard to coming here. First and foremost is the redbug that I have said so much about. Last winter we were troubled almost none at all—at least not until warm weather came in March and April. This winter they seemed to be unusually bad from the time we came here, about the first of November, until almost up to Jan. 1. Since that they seem to have let up considerably for some reason or other. Now, after trying a great variety of remedies, one given me by my good friend neighbor Abbot, I think, is simpler and perhaps more effective than any thing else. It is simply this: Take a daily bath in the morning, and before you put on your clothing rub yourself over pretty well with soapy water and let it dry on instead of wiping it off. You may object to this sort of treatment; but I have used it now for several weeks, and can not discover any ill effects. Of course, the soap is nicely and thoroughly washed off when you take your next bath; and after the bugs seem to let up, or you are not obliged to go out among the grass or bushes or in the woods, you can omit it. By the way, people living in town, who do not go out among the dry grass, and brush against the palmettos or run against rotten logs in the woods, are seldom troubled at all. By staying away from the country, and especially keeping out of the fields and lots where there isn't a trodden path, you will have very little trouble.

The next trouble I am going to mention will make you smile a little. It is mud-wasps. During the past six or seven winters that we have passed in Florida we have not noticed them very much until during this past winter. With the excessive rains of the past summer it seems as if the wasps must have been more plentifully supplied with mud for building their nests than ever before. You may wonder what harm they do by building these mud nests. Let me digress a little to explain. Mrs. Root has all along wanted some kind of blinds or shutters to our windows. The sun here in Florida gets to be pretty hot, even in December, January, and February, and she thought it would be a fine thing to have the windows shaded when we go home in the summer so that the sun may not come through the glass and injure the floors and every thing else that it strikes. Of course, you can put up curtains to the windows; but after having tried curtains, even cheap cloth ones, such as we should like to leave while gone, and having what they call the "silver moths" eat them all to shreds, we abandoned the curtains. These mud-wasps seem to take it for granted that the green blinds put on our windows were just there on purpose for them to build their mud houses all over the inside. In fact, some of our window shutters were so plastered that we could not possibly open and shut them. It was a real task to "chisel" out the mud so as to get them down and clean out the debris. They built their mud houses all over my tool-house, stuck things together, and even made quite a big mud nest on the under side of the cover to my automobile; and at every turn we find all sorts of utensils and every thing else stuck together by wasps. There is, however, a redeeming feature, as there is with almost every nuisance that we meet in this world of ours. The redeeming feature is that the mud-wasps are fierce enemies to common house-flies, and they clean out the flies so effectually that there has been scarcely a fly visible, outdoors or in, so far this winter. Very likely the wasps are bad only during particular seasons or at certain times; and it is true that we have never seen them any thing like as bad as during the past winter, or, rather, the work, perhaps, that was done during the past summer. As I have suggested, perhaps the dampness may have had something to do with it. After hearing the above, Mrs. Root says I have not put it strong enough. The blinds and windows-sashes to some windows were so plastered with mud nests they could not be stirred "a peg" until the nests were "chiseled" out. Then we sandpapered the

woodwork and painted it over. This is probably one reason why so few *slatted* blinds are seen in Florida.

I have just alluded to the silver moths, and they certainly are a pest here, and no mistake. Every thing woolen must be carefully tied up in a paper bag or protected some way, for they would be sure to eat it to shreds. Of course, moth-balls are something of a remedy, but not entirely so. Where we kept quite a quantity of moth-balls, there were very few silver moths.

This leads me to my third objectionable feature here in Florida—the roaches. I believe these are sometimes called cockroaches, but I don't just like that name. The ones we have down here are much larger than those commonly seen in the North—at least they are larger than any I have ever seen there. They are so big that they make a pretty good bite for chickens when thrown to them, as poultry are very fond of them. They are great black bugs, but very *thin*. I suppose they are thin on purpose so they can slide through small cracks between doors, windows, and almost anywhere else. On account of their thinness, and their habit of pushing in to almost every crack or crevice, it seems almost impossible to "fence them out." Of course, there are poisons for them, because they are voracious eaters; but if you poison the cockroaches and throw them to the chickens the poison will kill the chickens also, so there is not very much poisoning done here. Cockroaches are a nuisance, because they are always hungry for any thing in the line of starch or mucilage. They make it their principal business in life to eat up the papers and wrappers, or any thing that is pasted on to a box, bottle, jar, or any thing else. I even had a little bottle with a label "Strychnine" pasted on it, and about the first thing they did was to eat off the label. I suppose they thought if they got the label off they would be immune to the effects of the poison, which proceeding is, after all, about as sensible as some of the remedies that some human beings take for the ills that affect humanity. Now, we have found by experience that there is no use trying to label any thing down here. It seems as though they have a mania to hunt up the most important words in the label and eat that out first. When you come to examine your medicine, eatables, etc., that have been carefully labeled and put away, you will find that the labels are not readable on account of the cockroaches. I am not quite sure, but I think that, when they can not find any thing else to eat, there are certain kinds of paper that have something in their makeup which they manage to subsist

on; for it seems to be a passion with them to riddle every thing in the line of books and papers that they can get at. The redeeming feature of the cockroaches is that they are such excellent food for poultry; and if poultry could be allowed to run around the house they would thin them out to a great extent.

There is only one other drawback that I think of just now, and that is the Florida mosquitoes. I am glad to say, however, that there have been very few of them here this winter. In fact, I have never been troubled any winter with the mosquitoes in our neighborhood. Mrs. Root says, however, that a mosquito will find her if they do not seem to find anybody else; but by keeping our doors and windows carefully screened it is seldom that a mosquito gets inside the house. There is, however, something else along that line that I find exceedingly annoying—the little bits of gnats, almost invisible, or what I suppose are sometimes called sandflies. If you have any especial work that you are very much interested in that is worrying you and making you nervous, it seems as if these gnats take especial pains to get in *their* work at just that time, and make life almost unbearable. For instance, if you are at work at the automobile, and something puzzles you, and you are in a great hurry; also suppose that your hands are so smeared with black grease that you can not touch your face or nose or ears, or any part of your clothing; suppose, also, that you are getting "sweaty under the collar," then just at these times it seems as if they took especial delight in taking advantage of you. Let me say, however, that they are seldom troublesome unless it is about sundown and at the close of day. I have known them also to be very annoying at certain times early in the morning when we have muggy rainy weather. Sometimes, when I find it time to gather my eggs, and am a little late about it, these pests seem almost unbearable; and if it were not for that precious remedy that I have several times mentioned, and which has also been mentioned in our government bulletins, the "oil of citronella," I don't know how I could get along. We have two little bottles of it, one in the cupboard and one out in our tool-house. These ounce bottles, bottle and all, cost only ten cents, so it is not a very expensive matter to have plenty of the oil of citronella close by. I simply take out the cork, press the mouth of the bottle on the palm of my hand, put it back, and put in the cork. Rub the palms of the two hands together, then take a rub around your neck, over your eyes, and on your forehead,

another around your wrists and backs of your hands, and the sandflies will bid you good-by. Sometimes in the evening, when I want to work in the garden I should really have to give it up if were not possible to go to my bottle of citronella. After applying that as directed above, I can go on and work in peace and quietness. Citronella is used, I am told, largely by hunters and fishermen, and it seems to be a perfect remedy for almost all sorts of insect pests. In fact, it keeps off the redbugs I spoke of very well if you rub some of it around your ankles and the tops of your shoes before you go out to work in the fields.

I forgot to say in the proper place that mosquitoes are very annoying to babies unless the house is screened and protected, so that you can keep them out. A great many people come into Florida to spend the winter. To save the expense of renting, they build little cheap houses. In fact, there is no end to the cabins and houses, all the way from almost nothing up to the fine houses that we find here. The people who bring babies into these little houses, where there is no way of fencing off the insect pests, often find themselves in serious trouble, or at least the babies do, and some of the poor little innocents have their little lives almost worried out by these insect pests if some means is not taken to keep them away.

SWEET CLOVER; HOW THE "NOXIOUS WEED" IS COMING TO ITS OWN.

We copy the following from a little poster mailed us by our good friend Frank Coverdale:

SWEET-CLOVER PICNIC.

Have you seen a sweet-clover pasture? Have you seen sweet-clover hay? Have you seen washouts held by sweet-clover roots? Have you seen the effect of ground limestone on sour soil? Are you interested in these things? If you are interested, come to the farm of Frank Coverdale, four miles southwest of Delmar, on Tuesday, July 29, 1913.

Bring your family and a picnic dinner. We will meet at eleven o'clock, have a picnic dinner in the woods, listen to a short program, and then spend the afternoon seeing the one hundred or more acres of sweet clover on this farm, which has become known all over the United States. Sweet clover is being used on this farm as a pasture, and a hay and seed crop. Mr. Coverdale has some small test plots which show very plainly the value of ground limestone in sweetening the soil and making crops grow better. No one has a better opportunity than the Clinton County people to see just what the sweet clover is good for. Don't take anybody's word for it. Come and see.

Bureau of Plant Industry of U. S. Department of Agriculture, Iowa State College of Agriculture, Agricultural Committee of Clinton Commercial Club, cooperating.

Of course the date, July 29, has gone by; but we give the contents of the above poster to let you see how the Department of Agriculture, Washington, as well as the Iowa

State Agricultural College, recognizes the value of sweet clover to the nation at large.

A full report of the proceedings of this sweet-clover picnic will be found in the new edition of our little book, now in press, "The Truth about Sweet Clover."

SWEET CLOVER; CHICKENS CATCHING DRONES, ETC.

Find enclosed a stamp for which please mail me any literature that you have regarding sweet clover. I believe you had a book entitled "The Truth about Sweet Clover." I met a very intelligent farmer here who wishes to find out something regarding it with a view to sowing, but he had been told that he could never get it off his farm if he got it on.

I have read in GLEANINGS several times about chickens eating bees. I have some chickens about a month old that are smarter than any I have read about. A few days ago there was a scarcity of honey; and the bees, being in box hives that I had not yet transferred, had lots of drones, and those chickens would wait until they saw a worker bring out a drone, and then they would grab the drone. They could also tell the drones on the wing. I watched them do this two different times. There appeared to be only two chickens that bothered them, and in no case did I see them touch a worker; but they seemed to be afraid of them.

So far I think the honey-flow very light here; but as to what is to come I know nothing, as this is my first year here.

Vivian, La., June 25.

C. E. HAMMOND.

We are sorry to tell you that our little book on sweet clover is out of print; but we are working on a new edition, and will get it in the hands of our friends as soon as possible.

Tell that "intelligent farmer" that he is certainly behind the times in one respect. It is true that sweet clover was once called by some people a noxious weed, but that time is past. Consult your experiment stations or almost any agricultural paper printed, and they will tell you that sweet clover is now recognized as being next to alfalfa. In fact, it prepares the soil for growing alfalfa better than any thing else in the world. Because domestic animals have to be taught to eat sweet clover at first has given ground to this notion. After they once get a taste for it they prefer it to any other clover; and the best thing about it is that it will grow on ground where no other clover will grow, and, in fact, where *nothing else* will grow; and after having grown it inoculates the soil with nitrogen bacteria so that almost any other crop can be grown profitably. It is now being recognized and grown all over the world.

As long as you can keep the two chickens that take the drones but not the workers they will be a valuable asset, and you had better hold on to them.

18,000 SALOONS OUT OF BUSINESS IN ONE YEAR.

That the dry movement in America is gaining ground is shown in the annual report of the Internal Revenue Department at Washington, for the fiscal year ending June 30. It shows that 18,000 saloons suspended business during the year.—*Wheeling Advance*.

NO. 17

Editorial

THE COVER PICTURE.

THE front cover of this issue shows in the background our Ault sidehill apiary where Inspector Morris made the remark that he would have to saw off one of his legs and splice it on to the other in order to inspect the bees. The sidehill is so steep that the cattle can not go up it if they would. The yard faces the south; and during cool or chilly days these bees will gather nectar or pollen when there is little or nothing doing at the other yards. The picture was taken with a Telephoto lens a considerable distance away.

ARRANGING DATES OF CONVENTIONS SO THEY WILL NOT CONFLICT.

In our last issue, page 558, in the editorial department, we suggested that the National Beekeepers' Association make some arrangement whereby the time of holding the various State and local conventions could be arranged on consecutive dates to enable certain prominent beekeepers to attend one or more of these meetings. We sent a proof of this editorial to Dr. Gates, and received his reply too late to be incorporated with the editorial above mentioned.

Dear Mr. Root:—I have just received the proof of your editorial concerning circuit conventions. It is excellent. I presume you were not present when a similar scheme was proposed at Cincinnati. I brought up the question of a series of meetings on consecutive dates in different quarters of the country under the auspices of the National. It seems to me this should be one of its chief functions. I recall Mr. Dadant's remarks in reply to what I said, but the time was not opportune to take action.

In Massachusetts, where monthly meetings are held, it could be well arranged to have one of these under the auspices of the National. I think this would be quite agreeable to the local societies. In fact, I am now planning a circuit of local meetings under the auspices of the State Beekeepers' Association with which the local associations are affiliated.

I am taking opportunity to present to the Directors your suggestion for their consideration as soon as it shall have appeared. Have you any details as to the machinery I could utilize?

Amherst, Mass., July 28.

B. N. GATES.

If the secretaries of the various State and local associations will correspond with Dr. Gates we feel satisfied that the scheme of dating could be arranged so that Dr.

Phillips, for example, of the Bureau of Entomology, could attend several important meetings instead of one or two as in the past. By the way, Dr. Phillips did not make this suggestion, but we believe that many of our States would be able to secure his attendance if the dates were made consecutive.

THE APICULTURAL EXHIBIT SHOWN AT THE AGRICULTURAL COLLEGE AT AMHERST, MASS.

ON page 434, of July 1st issue, in giving our report of the State convention of Massachusetts beekeepers at Amherst we referred to some very interesting exhibits that were prepared by Dr. Burton N. Gates and his students at the apicultural school. These exhibits were placed in one of the large rooms, and comprised a large list of beekeepers' supplies from several manufacturers, various apicultural novelties, old relics of bygone days, and bees and honey in various forms. This was one of the most instructive and elaborate exhibits of bee supplies and bee products that was ever given in the United States. The hope is that Dr. Gates may arrange to have a similar exhibit for the National convention the coming fall or winter.

Elsewhere in this issue we have given several views showing the exhibits as they were shown at Amherst. The only regret is that thousands instead of hundreds of beekeepers could not have seen it. As it is, we are trying to show it to thousands on paper. See pages 607, 608, and 609 this issue.

THE PREVENTION OF SWARMING IN THE PRODUCTION OF COMB HONEY; HOW IT CAN BE REDUCED TO TWO OR THREE PER CENT WITH REGULAR STANDARD HIVES.

A YEAR or so ago we illustrated Mr. Vernon Burt's scheme for the prevention of swarming when running for comb honey. At that time Mr. Burt was very much pleased, saying that he believed it would solve the swarming problem for him. The plan is, in brief, nothing more nor less than putting four $\frac{7}{8}$ -in. blocks under each corner,

between the brood-nest and bottom. This gives an entrance $\frac{7}{8}$ inch deep on two sides and the back end and in front, enlarging the entrance about $\frac{7}{8}$ inch more. You will find this plan illustrated and described in our A B C and X Y Z; and in this issue, page 610. Said Mr. Burt: "I do not have over two or three per cent of swarms; and, what is more, I do not even stop to cut out the cells. Yes, it does away with the nuisance of cell-cutting, and what few swarms I get can be easily handled."

Inspector Morris was along. Said he, "Mr. Root, that plan looks mighty good to me. If I know myself I shall be using it next season."

We have found Mr. Burt to be almost unerring in his opinions. He is slow to come to a conclusion; but when he does he is nearly always right.

It has been stated by authorities that swarming comes as a result of overcrowding, particularly of overheating the brood. The remedy, obviously, may be applied in one of two ways—reducing the force of bees by swarming or dividing; or, second, cooling off the brood-chamber by ventilation. This may be accomplished by the method illustrated on page 610 of this issue, or by the use of slatted dividers, *a la* Aspinwall. Whether the four-entrance scheme is as good as the Aspinwall we are not prepared to say. But certain it is, that Mr. Burt says he can eliminate all but two per cent by the simple expedient of raising the hive up on four blocks. Nothing else is needed—not even cell-cutting.

Others have advocated the plan, and have spoken highly in its praise. It is worth thinking about, brethren; and it is worth giving a thorough trial next summer.

The four little blocks would cost less than a cent, and the time taken to apply them not over a cent. Good investment! especially when it sometimes costs all a swarm is worth to get it out of a tree, sometimes, to say nothing about the loss of honey due to the loafing period just preceding swarming.

TWO VIRGINS LIVING PEACEABLY IN THE SAME HIVE.

We have just run across a case of two virgins in the same hive. The history of the case is as follows: On July 31 we introduced a ripe cell in a protector to a three-frame nucleus, which we supposed was queenless. The combs contained some sealed brood, but no unsealed brood. The cell was due to hatch the next day, August 1.

On August 8, in looking over the combs in this nucleus Mr. Marchant found this

virgin; and then, as he was about to place the comb back in the hive, to his astonishment he found another running about on the same comb and on the same side of the comb. The two virgins showed no tendency to fight, and all was peaceable.

Desiring to watch the outcome, Mr. Marchant looked over these combs each day. On Monday, August 11, he saw both virgins as usual early in the morning. About 10 o'clock, looking over the combs again, he could find but one of them at first, but finally located the other on the bottom-board, dead. Two hours before, both virgins had been running over the combs as unconcerned as usual.

There are three possible explanations: First, the nucleus, by some oversight, may have already had a virgin on July 31, when the cell was first introduced. The old virgin already in the hive, possibly because of some injury to the wings, had never mated, and was allowed to live, even with another virgin in the hive, until August 11, when the second virgin showed signs of having been mated, although she was not as yet laying.

Second, a young virgin returning from her flight from some other hive may have gotten into this hive by mistake. As she did not show signs of having been mated, her trip, if this supposition were correct, was evidently not a successful one.

Third, by an oversight there might have been a ripe cell in the hive at the time the second cell was introduced July 31. A cell from which a virgin had recently emerged on the opposite side of the comb seems to give weight to this theory. Unless by some mistake this cell in question, which the nucleus already had, had been put in just a day or two previous, the bees must have carried an egg from some other hive into the hive in question, for there had been no unsealed brood in these combs for some time.

The true explanation, we shall probably never know; but the fact remains that there were two virgins in the same hive for two or three days.

INTRODUCING OLD VIRGINS BY THE SMOKE PLAN; A SEVERE TEST.

The direct method of introducing with smoke according to the Arthur C. Miller plan as given in the June 1st issue, p. 370, was given a most severe test in one of our yards recently. Our Mr. Marchant had twenty-three virgins, which, according to his records, were six days old. They were so old, in fact, that they would fly from the

age, some of them actually doing so, being caught in the air, and some too old to be readily accepted by the ordinary methods of introducing. These were introduced by the use of smoke, and in fifteen minutes the grass was removed from the entrances as has been described. Out of the twenty-three virgins, twenty-three were safely introduced. The fact that the queens were virgins, and *old virgins* at that, makes the test all the more severe. Twenty-one out of the twenty-three virgins have been checked up laying. These virgins evidently went out to mate the day after being introduced. They were checked up laying six days after being introduced.

The advantage of the plan is in the saving of time and the elimination of the mailing-cage—always a source of danger from disease. In the case of laying queens introduced by that method we have had them laying in a few hours. Those same queens, if introduced by the cage plan, could not have been laying under 48 hours at least.

Mr. Marchant believes that there is one drawback in the plan; and that is in case of, say, a four-frame nucleus in a full-size hive. The great amount of space outside the division-board furnishes a retreating-place for the virgin if she is scared; and when the hive clears of smoke the bees may ball the virgin if she is sneaking around in one of the remote corners of the empty space. In a hive no larger than an ordinary nucleus, so that the virgin must keep between the combs, there is little chance for failure.

Mr. Marchant says that he and his father have used the plan enough in the South in years past so that he can absolutely guarantee that the young queen is not injured by the smoke. If a queen is rolled in honey, and then allowed to run in to be cleaned off by the bees, she has a sleek greasy appearance like an old queen, owing to the fact that she has been literally licked by the bees. Mr. Marchant thinks that nine queens out of ten so introduced are likely to be superseded in the fall.

It might be well to suggest caution in the use of the smoke method. Don't overdo it. Too much smoke may permanently injure the bees and the queen.

WATER FOR BEES IN MAILING-CAGES AND FOR SHIPMENT BY EXPRESS; A BIG STRIDE IN ADVANCE.

OUR readers will remember that late last summer we made the discovery that bees could not be shipped without combs during hot weather unless they were supplied with water. When this was done the pound

packages of bees would go through with the loss of hardly a single bee. This year we continued our experiments, and later on will publish some hundred reports showing how we have sent bees from coast to coast, from Maine to British Columbia, to extreme points in the South, with the loss of only about a dozen bees in three-pound packages. We recently shipped some 20 lbs. of bees to British Columbia, with the loss of only a few dozen bees. When it is remembered that there are about 4500 bees to the pound, and that the entire shipment aggregated 135,000 bees, the ratio of loss is practically *nil*.

In some shipments of pound packages the water-bottles broke; and in other instances, where the supply of water gave out before arrival the bees either arrived all dead or with only a few survivors. The use of water in the shipment of bees by express without combs has been so satisfactory that we have been reviving the idea of using the small water-bottle in mailing-cages for queen-bees. Some of our older subscribers will remember how over thirty years ago A. I. Root was enthusiastic over the result of his experiments in giving bees water in the mailing-cages. We asked him to look up his early article on the subject, and in *Our Homes* for this issue is a reproduction of it.

We have just begun the use of water in mailing-cages for long distances. If it is good for long express shipments, why should it not be equally satisfactory for a few bees sent by mail?

Very recently we have been putting some homeopathic glass vials, containing water, over cages of bees in our office. The bottles were first filled with water, after which a small slit was made in the side of the cork, when it was pushed down level with the top of the bottle. This bottle was then inverted over the wire cloth of an ordinary mailing-cage of bees. The bees were thus enabled to run their tongues up in the slit in the cork and drink to their fill. We found that an ordinary cage of bees would use up a little vial of water (about a tablespoonful) every two weeks. So far we have been able to keep bees thus watered for a whole month, and at this writing they are as lively as when we first put them up. We have recently perfected a little tin box for holding water in a mailing-cage. This box is circular, and just neatly fills one of the candy holes. In the center is a small perforation through which bees can drink. While we would not advocate the use of water for *short* distances, yet for *long* distances we believe it will save the lives of a good many hundreds and even thousands of queens.

We have determined one fact; and that is, that a comparatively dry candy may be used providing the bees can have access to water. When no water is supplied it is imperative that the candy be soft and moist. If too moist it will dissolve and daub the bees; if too dry they will starve within a few hours. To make a candy just right is a fine art. If we can arrange to give the bees water while *en route* by mail, the softness or hardness of the candy would be of no material consequence. Indeed, we now believe we can use a dry hard candy. Details and engravings will be given later.

The question may be raised, "If the use of water proved to be so successful with A. I. Root thirty years ago, why did he abandon it?" First, his scheme of giving water was imperfect. Sometimes the water would be fed too fast, wet the candy, and kill the bees. Later on, Mr. I. R. Good solved the problem of bee food for mailings, as he thought, by making a soft candy, mixing sugar and honey into a stiff dough. This looked so good that A. I. Root dropped his water-bottle scheme and adopted the candy. This food proved to be so satisfactory that its use has continued up even to the present time; and the only substitute that has been offered is a "fondant," such as candy-makers use in some kinds of candy. But with many of these candies, it is well known that a large percentage of bees and queens by mail will die if confined more than ten days; so it is apparent that something is to be gained if we can devise some scheme that will supply bees water in the mails, not too fast, but just fast enough to give them food and drink. In the mean time, A. I. Root's article in the Home papers in this issue, written 35 years ago, will be read with interest. More anon.

THE HONEY-CROP REPORTS.

THERE is but very little to add to our honey-crop report as given on page 560, last issue, except to say that the drouth has been excessive in certain portions of the country. This may kill out the clover for next year; if so it will have a tendency to steady prices for this year. See what our Canadian correspondent has to say in this issue. In some parts of the West the newspapers have reported excessive drouth, but late rains have relieved the situation. Mr. Wesley Foster writes:

Colorado was very generally visited with rain during the third week of July. At Boulder we had almost too much rain. Delta, Montrose, and Montezuma counties in the western part of the State were not so blessed with moisture, and their August flow would have been better had they had several rains

or one real good one, but the bees were working quite satisfactorily Aug. 1st. Aug. 6th one of my colonies in Montezuma County was building comb in the cover up through four supers. August and part of September, if not all, can be counted upon to furnish honey in the Montezuma valley while we can expect little after Aug. 15th in Northern Colorado. Aug. 1st my bees in the Montezuma valley were supered, on the average, two supers to the hive, so that I expect a fair crop from them.

Frank Rauehuss, of the Colorado Honey-producers' Association, sends a night-letter telegram as follows:

Since our last report weather conditions and honey-flow have been good in most of the producing sections of the State. Season about over now. Crop as a whole is better in quality and quantity than last year.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION,
Denver, Colo., Aug. 24. F. RAUEHUSS, Mgr.

There has been no severe drouth in this section of Ohio, and we may say this for the whole State. It was beginning to be a little dry when we had a copious rain on the 21st, and this morning, the 22d. The ground is soaked, and the roads are muddy.

We have received a great many honey reports, but are unable to publish all of them; but here are a few of them that have been taken at random—good, bad, and indifferent. Most of them, however, are good. These reports may enable some of the beekeepers of the country to dispose of their crops.

Things were looking pretty good until the rains ceased, though we are yet hopeful of the cotton flow and what comes from late bloom.

J. H. AND J. T. CLARK.

Munford, Ala., C., July 21.

No honey this season in this part of the county. Escondido, Cal., S. W., July 9. J. A. NELSON.

This locality is a total failure—no surplus. Many beekeepers will have to feed to carry them over to another season. We had only five inches of rainfall last winter in the southwest part of San Diego Co. Otay, Cal., S. W., July 12. W. A. BALES.

This county (Tuolumne) will have less than half a crop of honey; 60 lbs. per colony for bees well cared for in 12-frame hives is about what I am getting in a good season. It is close to 20 gallons for like colonies. P. D. HEROLD.

Lonora, Cal., C., July 4.

My apiaries are enjoying a fine flow of nectar.

THOS. J. STANLEY.

Manzanola, Colo., S. E., June 19.

The indications are that we shall have a fair crop of honey.

HARVEY SAID.

Pueblo, Colo., C., July 29.

This is one of the best years we have had for honey since I have been in the business—something unusual for this section on white clover.

HENRY HARRISON.

Torrington, Conn., N. W., July 3.

Prospects are good at present for a fine crop in this vicinity. The flow is just commencing, June 20. Bees are weak on account of light stores, long winter, and cold spring.

H. L. BRATY.

Hayburn, Ida., S. C., June 22.

Fair crop of white clover. A. M. KECK.
Odon, Ind., S. W., June 24.

Replying to your request, I will report the clover-flow is very good, and the end is not yet. The never failing basswood is on in full blast, but the bees are staying with white clover, just as if they were getting paid for it. Nearly all beemen here have the old granddad boxes, and are not getting any honey. PERRY FRANKLIN.

Newcastle, Ind., E. C., July 11.

The white-clover honey-flow is light; alsike is some better, but our crop is rather short up to date.

MOSES C. MORGAN.

Blue Mound, Ill., C., June 27.

The honey crop is about one-third of the usual amount. Quality is good. It will not be over half a' crop at best. H. W. DOERR.

Beardstown, Ill., W. C., July 10.

There is a fine flow from clover, and I expect a large crop. R. B. RICE.

Mt. Carroll, Ill., N. W., July 16.

This is the best season we have had for many years—a fine yield from both white and sweet clover. Hoopston, Ill., E. C., July 21. G. T. WELLIS.

White clover is plentiful, but nectar is scarce. It will not be over half a crop of comb honey.

Brooklyn, Ia., S. W., July 7. B. H. TRIPP.

White clover is a good crop; basswood one-third.

H. R. BROWN.

Cedar Falls, Iowa, N. E., July 14.

Bees are doing finely on white clover; big crop of honey from them in this locality.

Atlantic, Ia., S. W., July 8. JOHN DUFFORD.

Honey crop is short. It seemed we were to have a good flow, but for some reason it was cut short. There is a small promise for a fall flow.

Center Point, Ia., N. C. GEO. W. FREY.

The honey-flow through June was good; about 75 lbs. per colony; but it ended July 1, two weeks sooner than usual. July was very dry. Weather bureau reports July the driest on record. Prospect is poor for a fall flow; for that reason we shall not dare extract too closely; must leave plenty for winter stores.

Dixon, Iowa, Aug. 2. E. A. DONBY.

The heaviest flow of white-clover honey is now on that was ever known in this vicinity; but as the bees were about all killed off in the three abnormal years just past, the bulk of the crop is going to waste. I had one standard ten-frame Langstroth hive filled and partly sealed in six days last week. The rest of my colonies are doing nearly as well. Symptoms are favorable for a flow from basswood this season. DR. A. F. BONNEY.

Buck Grove, Iowa, W. C., June 24.

Bad drouth here. White clover is cut short; no rain from April to June 30; feeding my bees now. Kevil, Ky., S. W., July 8. J. G. VANCE.

The clover flow in this immediate section was cut short, being confined to about two weeks; but bees got about 100 lbs. to the colony of extracted honey.

J. H. HAUGHEY.

Berrien Springs, Mich., S. W., July 15.

We had the finest bloom of all kinds of clover in many years, but the hottest and dryest June I ever saw. The last of June all clovers were killed; honey-crop is very light, only 30 lbs. of comb to colony; extracted, 75 lbs. Prospect is fair now for a fall flow to winter. This is the shortest report for many years for Ionia Co. Bees are in fine condition.

Ionia, Mich., C., July 30. A. H. GUERNSEY.

The honey crop from clover is the best it has been in several years. L. D. ALLEN.
Scottville, Mich., N. W., July 21.

Our bees are doing fairly well this year.

ELMER HUTCHINSON.

Pioneer, Mich., N. W., July 21.

This is one of the best seasons I have seen in 32 years in this county for beekeeping, and we are getting a fine crop of extracted honey—from clover, raspberry, and milkweed mainly. W. HARMER.

Pierpont, Mich., N. W., July 24.

We are having a good flow of clover honey at this point. A. ROBERSON.

Lake City, Minn., S. E., July 21.

We are having damp weather, and the pastures continue to be white with clover. When the weather is fit they work at a great rate; but the weather is such that they can not leave the hive, at least half of the time. JAMES F. BRADY, JR.

Medford, Minn., S. E., July 18.

The white flow is over. Clover yielded finely for a few days, then the drouth burned it up. Basswood yielded but little, owing to cool nights; not more than half a crop of white honey in this locality.

N. P. ANDERSON.

Eden Prairie, Minn., S. E., July 20.

We are having a good honey-flow from white clover, but swarming has been the worst I ever saw. Colonies have already stored about 80 lbs. of extracted average, and we have plenty of rain, so it may reach the hundred mark or better.

JAMES F. BRADY, JR.

Medford, Minn., S. C., July 7.

The honey-flow stopped the 29th of June. Dry weather stopped it. Plenty of rain since June 30, but the flow did not come back.

IRVING E. LONG.

Marceline, Mo., N. C., July 12.

The white-clover honey-flow is still good. We need a little rain at present. The clover honey is the best crop harvested for years in this locality. Many thousands of pounds are going to be lost on account of a scarcity of bees. G. L. LAUER.

Queen City, Mo., N. C., July 8.

Four weeks of good honey weather has given us a large yield, and it continues. J. L. GANDY.

Humboldt, Neb., S. E., July 9.

I have increased my apiary of 190 colonies, spring count, to 250, and have 400 supers about finished, of the finest fancy honey (white and sweet clover) I ever wish to see, and the flow is just at its best at this date. I expect to harvest 20,000 sections of fancy and No. 1 honey this season.

BELL E. BERRYMAN.

Central City, Neb., C., July 22.

Some of my best stands have made three hivefuls of extracted honey up to date, and the season is not here for two months. EDW. SCROGGIN.

Greenfield, N. M., N. E., July 29.

Bees seem to be making honey. A. E. LASALLE.
Georgetown, N. Y., C., July 29.

Pretty good honey crop so far.

OREL L. HERSHISER.

Kenmore, N. Y., W., July 8.

We had a good honey-flow from clover—the best I have known for years. J. W. LEWIS.
Lockport, N. Y., N. W., July 15.

The clover crop in this locality was the best in four or five years. MYRON C. SILSBEE.

Cohocton, N. Y., S. W., July 23.

Dry weather still holds here, and has cut down the honey crop very greatly. I have not begun to take the crop yet, so can't speak with definiteness.

JAMES MCNEILL.

Hudson, N. Y., E. C., July 18.

Bees are not doing well in storing honey thus far this season in eastern New York. Buckwheat will begin to bloom about Aug. 1. The weather is hot and exceedingly dry, and crops are suffering for it. Middleburgh, N. Y., E., July 22. N. D. WEST.

The white-clover honey harvest came to an end with a snap in this vicinity last Saturday night, the 5th. Drouth was the cause. Rains in New York were all near the lakes. Basswood showed unopened buds on July 4; leaves were eaten by beetles or worms. White-clover honey is perfection in quality, but quite a lot of unfinished sections.

C. W. WILSON.

Canastota, N. Y., C., July 7.

Bees have been gathering honey for the last two or three weeks quite lively—first from white clover, and lately from sweet clover. At the beginning of the white-clover bloom, of which we had an abundance, things looked very dark. On account of the cold nights, quite a number with frost, during the first half of the bloom clover did not seem to secrete any honey—at least, bees did not store any; but since the appearance of warmer weather the prospect has become quite promising. Some of my better colonies have already made 150 lbs. or more of extracted honey.

G. C. GREINER.

La Salle, N. Y., N. W., July 17.

The honey crop here will be the greatest in years. Marion, Ohio, C., July 30. C. G. FRANCIS.

A great honey-flow is on here. L. A. TRUXELL.
Peninsula, Ohio, N. E., June 30.

White-clover bloom is in abundance; yield of honey fair; all hives strong, with bees' prospects good. Bayard, O., E. C., June 21. T. C. WILLIS.

Bees are in fine shape, and making lots of honey. I have 28 stands. JOHN WELBAUM.
Arcanum, Ohio, S. W., June 28.

The honey season here is about over, and I have the best crop I ever had. T. BARNES.
South Zanesville, Ohio, S. E., July 28.

There have been oceans of white and alsike clovers, but the floral matter contained scarcely any nectar. Too dry. Honey crop very short. Bloomdale, O., N. W., July 14. M. N. SIMON.

Old beekeepers tell me there never was such a honey-flow as this year. The fields are white with white clover. H. J. HAUDENSCHILD.
Loudonville, Ohio, C., June 23.

The honey-flow is about over with the exception of sweet clover, which will soon be. Our crop was fair. CLYDE CORDREY.
Bellevue, Ohio, S. W., July 7.

The season has been the best in 25 years in Clinton Co., Ohio, since I have had bees. Lots of clover and lots of white honey. BLANCHESTER, O., S. W., July 14. D. G. LIDDIL.

We are having a good honey-flow out here this year, although the weather is a little dry. HENRY V. BROWN.
Antwine, Okla., N. W., July 11.

At present the prospects look bright for a full crop of white-clover honey. The bees are working well. B. E. ABBOTT.
Lucan, Ont., S. W., July 9.

Honey-flow is good. All good colonies made two Danzenbaker supers, and have started on the third. Jamestown, Pa., S. W., July 17. D. B. HILL.

The honey crop has been a good one with me—very nice and white honey. WM. REIBER.
Spring Mills, Pa., C., July 18.

The honey crop is not as good this year, as it was dry in the first part of the season. H. C. BOYD.
North Mountain, Pa., N. W., July 12.

The honey crop through this section of the country is poor. ENOS O. STAUFFER.
Ephrata, Pa., S. E., July 1.

The clover-honey flow is now nearing the end, and has been one of the best for many years. Clover has been in bloom since May 26. The milkweed is now coming in bloom, and we expect a heavy crop. GILBERT S. YOUNG.

Munson Sta., Pa., C., July 11.

The fine rains and hot weather have caused the greatest rebloom of white clover I have ever seen, and the bees are working again equal to their best pace in June. I shall have to extract and clear comb-supers to give room to store the new crop.

Wilksburg, Pa., W., July 28. W. D. KEYES.

We are not living in a land of milk and honey this year. If a line were drawn across Eastern Pennsylvania and New Jersey a little north of Philadelphia, you would find no white honey north of this line worth mentioning. South Jersey has been enjoying a flood of sweets. I have had no swarming; and a season that is so poor as not to provoke a few swarms is no good for honey. F. G. FOX.
Pipersville, Bucks Co., Pa., S. E., July 10.

Honey harvest was over the last of June. Product in comb is very white, flavor delicious. First clover was early, May 15; but weather was too cold for nectar and for storing until after June 1, making the season very short. Returns are fair in quantity, fine in quality. Swarms are limited in this locality—i. e., about two natural swarms to twelve colonies. All supers off July 1, and dark honey is now going into brood-nests. Colonies have full stores, and are populous. T. CHALMERS POTTER.

Doylestown, Pa., E., July 19.

Honey, half a crop. D. E. NUCKOLS.
Chatham, Va., S. C., July 15.

I have been in the bee business over 60 years, and this is the worst season I have ever seen. My bees have consumed some 55 lbs. of feed since I set them from the cellar. I used up 3000 lbs. of sugar. C. M. LINCOLN.

West Rupert, Vt., S. W., July 16.

The honey crop will be a complete failure here this year—not a pound in sight. Drouth has ruined the clover. Basswood is to come yet, but we don't look for any honey. Worst year in thirty.

I. N. HOWARD.
Fair Haven, Vt., W., July 8.

Honey flood—increased from 42, spring count, to 84, and will receive about 8000 lbs. of extracted honey and 200 lbs. comb. HERM. J. ROEBEL.
Menomonee Falls, Wis., S. E., July 24.

We have a great growth of white clover for this time of year (July 23). I never saw the like. The bees are working quite freely on clover. I have a good crop of honey, mostly white clover. Basswood did not do much. A. D. SHEPARD.
River Falls, Wis., N. W.

Honey is rolling in at a great rate. The prospects are good. ELIAS JOHNSON.
Lovell, Wyo., N. W., June 25.

Stray Straws

Dr. C. C. MILLER, Marengo, Ill.

YESTERDAY the bees were fearfully cross, although storing heavily. The smoker was loaded with pure greasy waste, which we've never used much. Was it the fuel that made them so cross? Well, the smoker was emptied, and filled with wood. Bees just as cross as before, or at least kept on cross, and I don't know why. But I wonder if some verdicts about fuel are not hastily made, just as we would have decided against greasy waste if we had not compared it with wood. [See last Straw.—Ed.]

IN AMERICA no one seems to think of a hive-entrance anywhere except at the bottom, summer or winter. In Germany there are many hives with entrances near the top. In *Leipz. Bztg.*, 41, G. Leis tells of an old beekeeper who for 20 winters had closed air-tight the bottom entrance, allowing no chance for air to enter except through a bung-hole on top, and that was covered over so no light could enter. It would seem there was no chance for a winter flight, yet his bees always came out in good condition in spring. Luneburg beekeepers have for centuries used the upper entrance, and it is claimed that this secures greater freedom from mold and diarrhea in winter. [In going out with our inspector this summer we found entrances all the way from the bottom to the top of the hive, and some old boxes that had openings in half a dozen places. Bees were using all their entrances.—Ed.]

IN ENGLAND and in Europe drugs are more in favor for the cure of foul brood than here. Seldom is there a time when some drug is not lauded in German journals as a "sure cure," only to be replaced a little later by some new candidate. Now comes so high an authority as Dr. Maassen, who says, *Leipz. Bztg.*, 36, that no time should be wasted in such experimenting, as the disease can never be cured through chemical means. [Dr. Maassen is authority in Europe. We do not know why any one should fuss with drugs for the cure of foul brood. Some 25 years ago we tried out thoroughly the various drug treatments for the cure of American foul brood, but they all failed. Practically all the reports from reliable sources in this country show the same result. There have been cases where some honest investigators *supposed* they were dealing with the real foul brood, when the fact was it was something else. When they tried out the drug treatment it apparently brought about a cure.—Ed.]

WESLEY FOSTER says, p. 440, "When a queenless colony is found . . . set it on top of another hive and be done with it." A Kentucky correspondent asks whether his object in doing this is merely to unite or to give a queen, and asks what I would do with a queenless colony. Undoubtedly he means merely to unite without the trouble of giving a queen. What I would do with a queenless colony would depend. Early in the season, or with a weakling any time, like Mr. Foster, I would unite; although very early a strong queenless colony might be united with two or more others. Later in the season a strong colony would be given a laying queen from a nucleus kept to rear queens. If no such queen were on hand, I might wait for it, or I might give a virgin or a ripe queen-cell to the queenless colony. Emphatically I wouldn't try rear a queen very early, and just as emphatically I wouldn't break up a full colony because queenless in harvest-time.

A BURNING question is that one getting to be about burning cotton waste with and without grease. We've burnt lots and lots of cotton rags without ever noting bad effects. We never had much experience with greasy waste, but are now using some very rich in grease. I think it's the most lasting fuel we ever used—lasting, I should say, five times as long as the dry cotton. The smoke seems milder to breathe, and doesn't smart the eyes like wood smoke; but it seems to affect the bees more. With a smoker filled with it going its best, blown on top of a super, it makes the bees fly off in a cloud, instead of running down in the super. I think I never knew any other smoke to do that. [We believe we were the first to suggest and introduce greasy waste as a smoker fuel. Its trial in the first place was accidental. As we had quantities and quantities of it, and it continued to give excellent satisfaction, we kept on using it. In our judgment it is far ahead of any other fuel that was ever used. It furnishes a milder smoke, and yet subduing enough to do the work. It is lasting, and, most important of all, it does not gum up the smoker with creosote as do other fuels. It can usually be had for the asking at any machine-shop. But do not leave greasy waste stored around in a building near combustible material. It is subject to spontaneous combustion, and should, therefore, be stored in an empty hive or in a box or a small building remote from other buildings.—Ed.]

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

When I read of the bumper crop of honey now being secured in the East, I am led to think that, for the benefit of the market, it is perhaps just as well that our off year came when it did. Now that we are largely out of the market, we hope that our eastern neighbors will make a big hit, after which we shall be pleased to have our inning.

* * *

Wesley Foster, greasewood in *this* part of the world means almost any kind of shrub that is large enough to make a stick of wood (stove size) to sell; and the term, as nearly as I am able to learn, is derived from the fact that the Mexicans, commonly called "greasers," go out into the hills and dig up and make into wood the various growths of this kind.

* * *

A member of my family sent east for a collection of flower seeds, among which was to be a flowering sage. My wife was especially interested in this new sage, for she had hopes that it might be of the commercial seasoning variety. It has grown nicely since early spring, and I have discovered it to be nothing more nor less than the California white sage. If kept over until another season it might produce some bloom; but as a flowering plant for which it was sold I do not consider it very satisfactory.

* * *

I can not too strongly commend J. L. Byer for his stand on "an abundance of old stores on the hive during winter." This, in my opinion, is the greatest asset of successful wintering of a colony, whether it be in California, Canada, Maine, or Florida. The fact of the matter is the bees of a colony must consume a quantity of stores if they raise a quantity of young bees. Without plenty of old honey and a large amount of young brood a few days of bad weather will often cause the best colonies in the yard to become worthless.

* * *

Wesley Foster and J. L. Byer both condemn the book-record system for the beekeeper who runs hundreds of colonies. I have not used that system for a number of years, but am going to give it another trial, for I believe there is more time wasted, many times over, in opening hives in a large apiary to ascertain their condition from time to time than would be required to keep an efficient record. It makes little difference what the mission of inspection is. If

there is a record to refer to, one can many times check up the record-book in a few minutes and know just what colonies need to be examined. The value of a record for keeping track of the age and energy of queens is in itself a great help, and may often help to get rid of the old and worn-out ones before they become a detriment to the colony.

* * *

GLEANINGS of July 15, p. 480, quotes from the *Western Honeybee* of July 1 a criticism on my crop report in GLEANINGS, p. 327, May 15. This may be a just criticism in a way; but I think if Mr. A. F. Wagner, who makes it, would figure the part Imperial County would hold in the amount produced, and the demand for our wild-flora honey in preference to any other in years of heavy production, he would find that the amount from his county would not only be a small amount compared to the production of the rest of the southern part of the State, but that the demand would be no greater for it than for any other alfalfa-producing locality. When the trade, both home and abroad, is trying to find out about the California honey crop, alfalfa is not given more than a passing thought—only honey from those flowers that are to be found in our semi-tropical climate being considered.

* * *

Another disastrous brush fire has just been extinguished in Riverside County, and that, too, in one of the best producing locations. Some very heavy yields have been secured in years past from the country just swept by fire, much of it being especially fine for late buckwheat, though some fine sage localities were also devastated. The fire is said to have burned over about 40 square miles. Unlike most of these fires, this one started by lightning, and the cloud from which it came did not rain sufficient to extinguish the flames. I submit the following extract from the Redlands *Daily Facts*:

Among the losses sustained so far are A. Hasenauer, sixty stands of bees; Thomas Rawson, several head of cattle, and several hundred acres of grazing land, and two large apiaries; this same loss was sustained by others. Thousands of dollars of excellent grazing land in sage sections are ruined. Several other lost bees, many apiaries going up in smoke. It is estimated that 20,000 stands have been burned, it being impossible to remove them. Owing to the fact that country roads are not wide enough for fire-breaks, unlike government-built roads they serve no purpose, and are so narrow that men can not fight oncoming fire, and it jumps the roads easily.

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

The Toronto exhibition, known generally as the "National," has a world-wide fame for the excellence of its exhibits in general, honey not excepted. This year a radical change has been made in the honey department, and the exhibit will be looked for with interest. Instead of individual prizes being given, the National directorate have given a lump sum of money to the Ontario Beekeepers' Association, and asked them to put up a large and attractive exhibit. This is being done in the way of county exhibits being sent in, and the Association is to see that all is staged in an attractive way.

* * *

The circumstances mentioned on page 513, Aug. 1, relative to drones congregating in large numbers in certain places seems to be quite common. For many years I have noticed that the drones from our home apiary, as well as those from a neighbor's, about half a mile away, swarm by the thousands over a field about a quarter of a mile away from each of these two apiaries. Any nice sunny afternoon in July and August there is a great roar of flying drones in this place, and I can see no reason why this particular location is chosen; but the drones seemingly like the spot better than any other in the vicinity.

* * *

Since writing my last notes for this department, conditions have changed but little in the clover situation for Ontario. As forecasted then, the crop, generally speaking, is very light in eastern counties; light to fair in northern counties, and good to *very* good in central and southwestern counties. The markets are good, and in our own case all honey is sold at this date (July 11) except some pails that are held for winter sales. Quite a determined effort has been made by the wholesale trade in some quarters to bear prices, but in a general way the prices recommended by the crop committee are being obtained. A few beekeepers who had big crops, and feared low prices later on, sold at a figure below the committee's recommendation; but I suspect they see the mistake now. The Western Provinces of Canada take large quantities of honey; and as crops are good there this year, the demand is likely to be good and continue for honey all winter.

One feature of the honey market this year is that every small order from a family is likely to bring a repeat order in a short time. The reason for this is that the clover honey this year is the finest in quality that I have ever seen, and that is

going some, as Ontario generally produces some pretty good stuff in the honey line.

* * *

I heard a farmer once say that farming is a gamble on the weather. No later than a few weeks ago, one of the last men we would suspect of gambling made the same statement to me in regard to beekeeping. I refer to our mutual friend Mr. Pettit; and I know, Mr. Editor, it will shock you to learn that our friend is engaging in and advising others to go into a business that has a tendency to develop the gambling instinct that seems to be inherent in human nature in general. I will leave you to deal with him in the matter. I should just like to say that there is a certain amount of luck or chance in beekeeping that has all other rural occupations "beaten to a frazzle," to use a term quite familiar to you chaps "over the line." For instance, up at the Lovering yard, which is 100 miles north of our home, when there about May 24 I certainly thought by conditions in general that the bees would leave the others away behind that are in York Co. around our home, at least ten acres of clover up north to every acre around our home yards, to say nothing of other honey sources of which we have nothing here. The season is now over, and up north we have about 35 pounds per colony, while here the five yards have averaged four times that much. Shortly after I left the north yard this spring, late spring frosts damaged the clover badly, and then the prolonged drouth finished up the work. Here at home the frosts did little damage; and while we were a bit short of rain most of the time, yet some nice showers kept the clover quite fresh for a while, and the yield of nectar was very good indeed. In writing the July Notes I stated that buckwheat prospects were fine; but since that item was written we have had practically no rain, and now it looks as though we shall do well if the bees get enough buckwheat to pay the feeding-bill. It is now Aug. 11; and unless rain comes soon, certainly we can not get much buckwheat honey, as the plants are stunted and the ground all parched and cracked open in many places. These are commonplace occurrences, of course, to the beekeepers who have been in the business for years; but perhaps a recital of some of these things that are *likely* to happen may be the means of helping some beginners to realize that, after all, beekeeping has trials and disappointments to put up with as well as have other pursuits.

Beekeeping Among the Rockies

WESLEY FOSTER, Boulder, Col.

WESTERN EXTRACTED AND COMB HONEY.

The comb-honey producer has to be a better beekeeper than the extracted-honey man. If you want to take it easy, don't produce comb honey. But if you would prefer to worry over marketing more than over the preparation of supplies, why produce extracted honey? The western extracted-honey producers are up against the marketing problem far more than the western comb-honey men. When we can get 11 to 12 cts. per section for comb honey, and only 6 to 7 cts. per pound for extracted honey, more money is to be made in comb honey. I may be disputed on this, but I believe I am right in the majority of cases.

* * *

REMODELING HIVES.

The average western beekeeper has more empty hives than he wishes; and the question of filling them is an important one; but first it is well to go over them carefully and renail the corners so that the tin rabbets will be in solid. True up the top and bottom with a plane if necessary, so that they will not allow an entrance for bees any place but at the proper entrance. There is one gratifying thing about the best hives now sold—they are made deep enough so that you can plane off a little on the bottom to square up in case the hive is off a little. Hives now made for western trade are made deeper over the frames and below them to allow for shrinkage in this climate. In fixing up the bottom-boards do not forget to paint them on both sides. Put a 2 x 2 cleat at each end for a hive-stand if you do not use them. They strengthen the bottom wonderfully. My uncle, Oliver Foster, dipped all his bottoms, hive-covers, and bodies in boiling linseed oil. Then two coats of paint were applied. If you want to see hives that hold their shape, and last in this western country, you ought to see some of them.

In remodeling cases don't fool with any thing but a metal-roofed cover. The wood covers are absolutely "no good" for the western comb-honey man. With the extracted-honey man it is different. But I have yet to see the first all-wood cover that would not leak, and leak badly, in less than ten years' use beneath our western sun.

* * *

COST OF SOME BEEKEEPING OPERATIONS.

No. 1 sections cost about \$4.50 per thousand. Extra-thin foundation costs 55 cts. a pound. Scraping and cleaning supers and separators costs five cents each. A

handy boy or girl can make good wages folding and "startering" sections at \$1.50 a thousand. The expense for supplies as run by the average western beekeeper is about as follows. The expense is based on supplies for one hundred colonies. Three supers to the hive will be needed.

7200 sections at \$4.50, \$32.40; 50 lbs. extra-thin foundation, at 55 cts., \$27.50; scraping and cleaning 500 supers, at 5 cts., \$15.00; folding and startering 7200 sections, at \$1.50, \$10.80. Total, \$85.70.

By using No. 2 sections the cost may be reduced to \$27.00 for sections; and if a one-inch top starter is used instead of a three-inch the expense for foundation will be cut from \$27.50 to \$10.00. This, however, is doubtful economy. If one scrapes and cleans the supers and separators himself, not counting the labor, this item will be eliminated from the estimate, as will the expense of folding and startering the sections. But the busy beeman can not afford to do this work himself unless during the winter months, and even then a man's time should not be taken up with this class of work. By this doubtful economy in sections and foundations, and doing all the work oneself, the expense for preparing the supers for one hundred colonies will be \$37.00 instead of \$85.70.

For the normal increase, at least 25 extra hives will be needed, costing \$1.60 each, or \$40; and for these hives 30 lbs. of medium brood foundation will be necessary. At 45 cts. a pound this will be \$13.50, making an additional expense of \$53.50 for the increase.

A man will be able to nail up about ten hives a day. It will require four days to nail up and paint 25 hives. At \$2.50 a day we have \$10 for this item.

The cost of new equipment which goes into permanent fixtures should not be charged in the season's cost unless it is subtracted from the value of the increase that is made. Ten dollars should be allowed for miscellaneous supplies. Here, then, we have an expense of about \$100 if labor is not counted, and \$160 if labor is counted, for preparing 100 colonies for the honey-flow.

Of course, no feed for bees is included or rent for location or rent of shop, or feed for horse or care of auto. With the strictest economy the expense for supplies for comb honey can not be brought under \$1.00 per colony, and it can easily be made to run up to \$2.00.

Conversations with Doolittle

At Borodino, New York.

WHY SO MANY DRONES?

"If I am correct, you advise that only a little drone comb be allowed each colony in the apiary, except to those which have queens especially selected from which to rear improved stock for mating purposes. Now, there are a few of us who think that there is some unknown or unseen advantage in having a lot of drones in a hive, just as we find them in box hives, or where the bee-keeper pays no attention to this matter of comb-building. From a close watch I feel assured that colonies having their own way in this matter are fully as prosperous, if not more so, than those from which I have carefully excluded all but about an inch of drone comb. This being the case, are not you folks who are advising only an inch or two of drone comb making a mistake?"

It may be well to look into this matter a little, as I do not wish to advocate a false doctrine. In a state of nature, colonies do not exist in very great numbers in any one place; and when colonies are from one to several miles apart, either in hives or in trees, it becomes necessary that a great number of drones emerge in each colony in order that a sufficient number of such be found within easy reach to render the queen's bridal flight successful. Otherwise the queen is liable to be caught by birds, or overtaken by some mishap through long-continued roaming, so that she may never return. Nature is very lavish, and has provided a great number of drones in a hive, or any home of a colony of bees, at swarming time, and this is but another evidence of the correctness of the theory of natural selection. In other words, there must be enough drones reared in each colony to make it an almost absolute certainty that the queen of this colony (or of any other for that matter, for several miles) will be sure to find one in a few minutes, or the half-hour at most that she spends in the air. Upon her life and successful mating the existence of the colony depends, as there are often no other means left for the continuance of her colony.

But in case of 10, 25, 50, or 100 colonies being congregated together, all of this, through domestication, is changed, and thus the drones reared in the two or three colonies from our selected drone mothers will serve the same purpose as if those two or three hives were the only ones within the range of flight of the bees. From this it is plain that it is useless to rear such a great number of drones in every hive.

That the drone-rearing colonies are any

more prosperous than those being restricted to an inch or two of drone comb is something I have never been able to discover; but, on the contrary, I have many times noted that this multitude of drones consume so much of the honey gathered by the minimum number of workers, necessitated through a minimum amount of cells of the worker size, that very little surplus could be obtained from such colonies, to say nothing about having to supply the needed amount of stores for winter. What advantage can there be in the rearing of a large number of drones? They do not work; they are never seen out in the fields on the bloom which secretes nectar; they eat the honey of the hive, and their rearing decreases the number of workers reared. Are these facts to be laid aside and overlooked? In a square inch of comb, only about 36 drones can be reared, while the same space will give about 55 workers, both sides of the comb being reckoned as a matter of course. Taken in round numbers, a square foot of comb will give 8000 workers, or about 5000 drones. Then it takes 24 days of time in which to perfect these drones, while the workers will emerge in 21 days from the laying of the eggs by the queen. And it will take about the same amount of food for the rearing of each, since both occupy the same space. Is not this reasonable? And when all the 8000 have emerged from this foot of comb we have a fair-sized swarm of honey-gatherers added to the other forces of the hive which will almost if not quite turn failure into a successful surplus. Hence these drones that are reared at great expense are in the way of the household duties of the home; and they decrease the profits by the loads they carry out on every flight.

It is claimed that drones keep the brood warm; but is it not plain that, when there were fewer bees in the hive than when they arrived, *they* had to be first kept warm? And these drones emerge only as warm weather is coming on, at a season when there is little danger of any brood getting chilled. Then on all cold days, and as night comes, all the forces of the hive are gathered together there, so this warmth from the drones is hardly a sufficient plea for their existence.

All things considered, it seems clear that it pays to exclude all except an inch or two of drone comb from all but one or two colonies in any apiary having ten or more colonies in it, allowing much drone comb only to our best drone-breeders.

General Correspondence

A PLEA FOR EXPERIMENTAL WORK IN BEE IMPROVEMENT

BY W. WHITE

The part played by man in the past in modifying the honeybee to his own uses appears to have been insignificant, principally for the obvious reason that, until recent times, the greater portion of the life-history of the insect has been a closed book to him. That some modification has been effected is scarcely to be doubted; and, in view of the immense strides that have been made in this region of applied science during the past decade, it is not too much to hope that the near future contains the fulfilment of the beekeeper's desire for a "better bee."

A thorough and searching investigation of racial characters is a necessary prerequisite to any substantial advance in this direction—a fact which, in the discussion of the subject of bee improvement, has hitherto been almost entirely ignored. Scientific inquiry itself has been confined almost wholly to the study of anatomy and disease, and but little work has been undertaken to ascertain the manner of inheritance of the characters of the bee.

As is well known Mendel experimented with bees many years ago, but, unfortunately, the records of these experiments have not been discovered. The work has been recently taken up again by several biologists in Europe, and doubtless the results of their investigations will contain much that will be of great interest and, possibly, of supreme importance to the beekeeping fraternity. The work of Mr. Sladen is fairly well known, especially in Britain and in Europe generally. He has conclusively demonstrated that Mendelian principles obtain in the case of the honeybee. The recently published results of his observations may be summed up as follows: In the cross between a golden queen and a black drone, segregation of the factor for the golden color from that for black occurs in the second generation. The workers and queens of the first generation of the cross consist entirely of an intermediate form, while the female offspring of this generation of intermediates consists always of goldens, intermediates, and blacks, the intermediates being usually greatly in excess of both the goldens and blacks. The evidence furnished by Mr. Sladen's experiment shows that, as regards color characters, the bee exhibits the same mode of inheritance as other animal organisms.

It is an unfortunate possibility, however, that the investigation of bee characters may proceed along lines that will prove of but little interest or of immediate benefit to the beekeeper. The experimentalist in this department of science usually selects for his purpose some easily recognizable physiological character; but in the case of the bee such characters can be of but little economic value. The utility characters of the bee are such that they are not likely to commend themselves to the scientist as furnishing material for research work in heredity, and the question will doubtless arise in the minds of many beekeepers as to whether some effort should not be made to induce government authorities to institute special experiment stations for work along the line I am suggesting.

What constitutes the "better bee" has been discussed at great length during the past few years, and some extravagant claims have been put forward as to success achieved in producing wonderful strains of bees. If Mendelism teaches us one thing more than another it is that such claims, based as they are upon work of a merely empirical nature, are extravagant. Breeders must be reasonable in their demands. They must not expect to create. They may only hope to discover, at the most, what already exists, locked up though it may be, in nature's wonderful storehouse of gifts. The breeder is an explorer; but the possibilities that are open to him are boundless. He must bring to the work all the patience and skill he is possessed of; for the task of unraveling and isolating factors which make for "improvement" is often most intricate and difficult. The element of elusoriness that enters into the problem as a result of the peculiar nature of the bee adds greatly to the difficulty of the work. Yet notwithstanding all that may be said in regard to the complications resulting from parthenogenesis and the difficulty in controlling matings, there is not the slightest doubt that improvement of the bee is feasible.

The necessary preliminary analysis of utility character can not be made under the conditions that ordinarily obtain in the practice of beekeeping. To ascertain and to distinguish between clear-cut utility characters requires an absolute uniformity of conditions that is never found in the commercial apiary; for the bee responds to its environment with an exceedingly high degree of sensitiveness. Every-day experience proves, beyond a doubt, that great differences exist in utility characters. With-

in the limits of large yards the extremes of variation are often to be found. But the exact range of variation is difficult to measure, and, in the ordinary way, it is almost impossible to gauge the extent to which variations may be due to environmental conditions on the one hand or to factors inherent in the bees themselves on the other. The large yield may occur in a very mediocre colony, and be due to a fortuitous combination of favorable circumstances, while at the same time, by reason of adverse circumstances, a colony of a much better type may fail to do itself full justice, and will fall short in the harvest. If, then, a means can be devised whereby uniformity of conditions may be insured, a large part of the difficulty in obtaining a correct conception of the nature of the utility characters of the bee will be overcome, and the breeder will be well on the way to discovering the potentialities of the subject.

To illustrate the value of analytical methods of investigation, I will refer briefly to the results of Dr. Raymond Pearl's studies of fecundity in poultry, carried on at the Maine Agricultural Experiment Station. Nearly every poultryman who has endeavored to improve the laying qualities of his flock knows how difficult it is to fix a strain of fowls perpetuating the high-laying powers of any particular hen. A fowl showing an abnormal egg-record can not, in fact, be depended upon for giving a progeny that will show a capacity for egg-laying above the average. The ordinary laws of heredity do not appear at first sight to apply in this respect. The following summary of Dr. Pearl's experiments will furnish a solution of the problem, and at the same time serve to indicate how similar questions may be attacked in the case of the bee. The facts established are:

1. Fecundity is inherited strictly in accordance with Mendelian principles.

2. Observed individual variations in fecundity depend upon *two* separately inherited factors. The first of these two factors determines a winter production of eggs numbering from 1 to 30 per bird. The presence of the second factor, in addition to the first, increases the winter production above 30 per bird.

3. High fecundity is manifested only when *both* of these factors are present together in the same individual.

4. Either of these factors, when present alone, causes about the same degree of low fecundity to be manifested.

5. One of these factors, viz., the second, is *sex-limited*, like the barred-pattern factor in the Barred Plymouth Rock.

6. There is a definite and clear-cut segre-

gation of high fecundity from low fecundity in accord with simple Mendelian principles.

Those acquainted with the interesting facts of "sex-limited" inheritance will readily understand from 5 how it is that simple selection of highly fecund females is not sufficient to insure a similar degree of fecundity in the progeny, and they will likewise appreciate the nature of the difficulty which has puzzled the poultry-breeder to so great an extent. Results such as these show conclusively that anomalous conditions, apparently defying the ordinary laws of nature, are often capable of simple explanation when subjected to careful analytical scrutiny.

Fecundity in the bee is a character of very great importance. Other things being equal, the highly fecund strain will produce a proportionately large amount of surplus. There are good reasons for believing that distinct and clear-cut degrees of fecundity may exist in bees as in poultry. Without doubt, there are strains which exhibit very striking divergences from the normal; and the mere elimination of the least fecund strains would result most probably in the raising of the standard to a very considerable extent.

Beekeepers often speculate, without hesitancy, as to the nature of the characters upon which proficiency in honey-gathering depends. In the absence of special investigation, however, the matter must remain largely one of mere speculation. Under the usual methods of beekeeping, subtle yet important differences of character may pass unnoticed, or their value be wrongly estimated. For this and other reasons, special preparations and methods of procedure are necessary for the experimental work of testing characters. I would suggest, as a first essential, that all the queens for the experiment should be of precisely the same age, and have been reared under conditions as nearly alike as possible. They should be introduced simultaneously, each to an equal weight of workers, and hived upon empty combs. In every possible way the greatest care ought to be exercised to prevent any risk of disturbing factors entering to lessen or destroy the accuracy of the results of the experiment. Thus it is possible to obtain an accurate estimate of the manner and extent of the egg-laying of the various queens under observation. When sufficient time has elapsed for the whole of the original workers (which should preferably be of a different race from the queen) to have disappeared, and the hives are populated by the offspring of the experimental queens, the various observable characters of the

workers may be placed under surveillance. For the purpose it will be better to shake the colonies at this point, and to rehive them upon starters of foundation. The capabilities of the colonies in the matter of comb-building and honey-gathering may thus be gauged, the means of practicing selection are provided, and the work of eliminating the "unfit" may be proceeded with if this latter be the object of the breeder.

The scope of all experimental work of this kind must largely be determined by the originality and aim of the investigator. Whether his purpose be to establish a new race of bees, in which case he will probably work with at least two of the ordinary races, or merely to isolate the best strains in a given race, his real difficulties commence with his work of breeding. For this, mating-stations appear to be absolutely necessary. This subject of mating-stations has received considerable attention of late years, and there appear to be no obstacles in the way of finding suitable localities for them. The one essential condition is that there be no honeybees in the neighborhood other than those to be used for the special purpose of mating.

It should not be forgotten that similarity of appearance is no sure guide to inherent qualities. I heard it suggested at a recent convention that yellowness in the bee indicates ability to resist European foul brood; that the yellower the bee the more immune is it to the disease, and *vice versa*; that the darker the bee, the smaller the degree of resistance possessed by it. The evidence upon which such a statement is based is of the flimsiest kind. That the Italian race has proved itself better able to resist European foul brood than the black bee of this continent may, perhaps, be granted. It is not at all difficult, however, to adduce evidence showing that the black bee of Britain and the neighboring regions of Europe possesses the same degree of immunity as the Italian. Two individuals, undistinguishable in appearance, may show in their respective progenies characters greatly differing from each other. The purity, or otherwise, of a queen is not decided merely by color, but by the nature of the factors existing in the reproductive cells which give rise to the various distinguishing characters of the race or strain.

In his efforts to produce a race which shall combine the greatest number of desirable characters the bee-breeder of to-morrow may be under the necessity of making selection from several races. His task, as I have already pointed out, will be principally to determine what the factors are upon which the various desirable utility

characters of the bee depend. It often happens, as in the case of fecundity in poultry, that what appears to be a simple character proves, upon analysis, to result from the interaction of two or more distinct factors. As soon, however, as the analysis has been made, and the constitution of the characters expressed in terms of Mendelian factors, strains can be built up which will breed pure for those characters. The vague ideas of past generations must give way to a more exact knowledge and to clearer conceptions of what is involved in the processes of heredity. The guidance of science must be sought and followed. The problems arising from the parthenogenetic nature of the drone are largely mathematical, and not by any means incapable of solution, while the difficulty in controlling matings is minimized in its importance by the fact that the colony is the unit we are working with and not the individual insect, whether drone or queen. The object of the breeder will be to obtain colonies in which both the male and female progeny will transmit to the descendent colonies the desirable characters already analyzed, and his full efforts will be directed to this end. In spite of the abnormal conditions attached to bee-breeding operations, in spite of many difficulties of which even beekeepers are not cognizant, one has every reason to hope that, when the best and most reliable scientific methods are applied, the same success will attend the efforts of the bee-breeder as has accompanied those of workers in other fields of applied agricultural science.

Brantford, Ont.

How to Remove Bees from a Wall or Tree by Means of a Bee-escape

There is one little discovery I have made which I have never seen described, which has worked successfully. When bees have located in a house or tree in such a way that it is difficult or impossible to remove and save the swarm, I close all exits except one and place a wire cone over that one, leaving a small opening through which the bees can pass out but never return. The cone must be carefully tacked around its base. If a hive is conveniently placed containing a frame of brood, the bees will soon take possession, and will prove to be something of value instead of a detriment, as is often the case. I have succeeded, without the use of the brood-frame, in capturing the whole swarm, which was soon well provided with stores and brood.

Long Grove, Iowa.

GEO. W. CURTIS.

[The above is the principle of the Fisher plan described in The A B C and X Y Z of Bee Culture. A Porter bee-escape will be found rather better than a cone escape, and at the end of four or five weeks it should be removed to allow the bees, the majority of which are now in the hive, to rob the honey out of the combs in the wall or tree. When the escape is removed, sulphur smoke should be blown into the opening to kill the few bees remaining and the queen. A new queen must be provided for the colony or else young brood given from which the bees can rear a queen.—ED.]

HONESTY IN ADVERTISING QUEENS

What Constitutes a Golden?

BY PENN G. SNYDER

It is an acknowledged fact that, when goods are bought from description in some advertising medium, the article purchased should be as represented. It is very unjust, to say the least, to bargain for one thing and then receive something that possibly does not approach in looks or value the impression received from the advertisement.

There is absolutely no harm in saying in one's advertisement, "I have the finest queens ever produced." Such a statement is a general one, and can be accepted as such when summing up; but if the adver-

tisement reads, "My bees are all free from foul brood," or "My red-clover strain have tongues 23-100 of an inch in length," or "My goldens are full six-band," then a specific promise is made to the intending purchaser, and it would be well for all concerned if the advertising manager of the periodical should demand of the advertiser a proof of his assertion.

There is nothing in the world much cheaper than talk. When put in the form of an advertisement it becomes a little more expensive; but if it comes to making statements that are not true in the published advertisement, there is no limit to the claims that can be made. No doubt such advertisements do the honest advertiser a great injustice, as his statements are not so florid

The collection hall of the Massachusetts Agricultural College, holding the exhibit at the beekeepers' convention, June 11 and 12.

Partial view of the exhibits.

or highly colored, and so do not look as attractive to the buyer's eye.

Take, for example, the yellow coloring of golden bees. The advertiser can say, "I sell yellow bees, the brightest and best; strictly first-class goldens. I have the finest goldens in the United States;" or he can say, "My bees run five and six band golden. My breeding stock runs full six-band gold; my breeding queens and drones flying are entirely yellow." When the latter statements are made, there is a specific promise, or supposedly a guarantee that such is a fact; but is it?

This is where the advertising manager should require, before printing such advertisements, full proof.

When such has been forthcoming and

demonstrated to his entire satisfaction no one can be harmed—neither the advertising medium, the purchaser, nor the advertiser.

The first four of the above statements are general. They really do not guarantee any thing definite; but the latter statements are of an entirely different character.

It is not the intention of this article to give the impression that any advertiser intentionally makes a misstatement. He believes his advertisement to be true, or practically so.

There is considerable ignorance among the beekeepers, if not the producers of queens, as to what constitutes a golden bee, as well as to how many bands or segments the bee possesses. Any bee that is very bright in a colony, if only three-banded,

Display of wax, including several samples of foreign wax in the rear. The large cakes show samples of different renderings with the equipment at the college.

Melting-tank and Hershiser wax-press.

could be called a golden; but that is not the purchaser's idea of the variety. A queen which will not throw a large percentage of four-band yellow or better should not be classed as a golden.

The best in the color line which has so far been produced is a queen whose worker progeny is practically all yellow with the exception of the last segment or band which is the tip or end of the abdomen.

A frame of bright yellow bees looks very fine to their producer, and he really does not know, as a rule, how many worker bees run three, four, or five band yellow. It is necessary to confine a number, not less than 100 workers, in a small dark cage which has a bee-escape attached;

then as the bees run out they can be held one at a time, and examined as to what their coloring may be.

This is a safe way of testing the amount of color in your bees.

The average examination is, no doubt, made by examining a frame of bees and trying to count the bees having different numbers of yellow bands. Such a method is too uncertain, for the tendency would be to count the same bee repeatedly, and not know it; and the brighter the bee the more quickly it takes the eye, and the more likelihood of such bee being counted more than once.

A queen whose worker progeny runs 90 per cent five-band golden is a very scarce commodity, and it is doubtful if there are half a dozen such

queens in the United States. Such a queen, or one not throwing such a good percentage of yellow workers, will produce an all-gold-

Sibbald and Hatch presses.

One of Vernon Burt's hives for the production of comb honey. Mr. Burt says this scheme of putting his brood-bodies upon four blocks so as to provide entrances for all four sides goes a long way toward eliminating swarming. See editorial in this issue.

en virgin in practically every instance, providing they do not become chilled previous to hatching. Her drones will be yellow from tip to tip, with a very little dark shading on the last two or three segments. They will run pretty uniform in coloring, and there will be no black ones among them.

Such is the best type of golden from the standpoint of color that has so far been produced.

It is assumed you will all agree that there have been far too many advertisements giving an impression which the actual stock can not substantiate. Taken from the breeder's standpoint, he might sell a certain number of queens by making large statements; but will the purchaser be satisfied? and will he buy again? That is the question.

If the publication in which the advertisement is printed guarantees its advertising matter, it certainly is not going to uphold this standard by accepting and publishing such advertisements; and the reader who may read between the lines will place less reliance on the journal than he otherwise would.

The buyer who expects a straight five or six band yellow bee will be most horribly

disappointed, and he certainly should have some redress when straight yellow five or six band stock is advertised.

There is no doubt that if the advertising manager of the periodical and the advertisers would come to a little better understanding they would see it is to their advantage as well as their duty to their readers and prospective customers to give the customer as nearly what they pay for as is possible.

A NEW SCHEME FOR STARTING QUEEN-CELLS

BY WM. A. SEDDING

The engraving shows my hive-tool and a contrivance for starting queen-cells from the egg. All are of my own invention, and made from such material as I could find on the ranch. The hive-tool is very handy. I have been using one like it for the last five years. It fits nicely in the hollow of the hand, and also slips into the side pocket like a gun.

To start queen-cells from the egg or larva without transferring, I take the cartridge

Wm. A. Sedding's hive-tool and method of starting queen-cells without grafting larvæ. With the brass cartridge shell the selected cell is cut down to the midrib; then the short piece of pipe is slipped over the cartridge and twisted around, thus grinding away the surrounding cells.

shell, set it over a cell I want to save, and push it gently down to the midrib. I then take the hub (either the wooden or iron one), and place it over the shell; then by holding the shell with the fore finger of my left hand I give the hub a turning motion with my right hand, thus grinding the surrounding cells down to the foundation. Then I lift both the shell and hub from the comb, and the cell is ready for the bees to start on, just as shown in the picture.

Monterey, Cal.

DOES BEEKEEPING PAY?

BY HENRY REDDERT

When I am asked whether beekeeping pays, I answer, "Yes and no," for it depends entirely on the one engaged in the business. If he has an irritable temperament he had better leave bees alone. If he is cheerful at all times in adversity as well as in success, I advise him to go ahead, provided he equip himself with the necessary theoretical knowledge to be gained from text-books and bee-journals before starting in. If one wishes to become a practical mechanic he must serve an apprenticeship of from three to four years. The same holds good in beekeeping.

I once asked an old experienced beekeeper who also raised sheep, having a flock of about 400, which of the two paid the better; and his answer was, "The bees." From

350 colonies, he had harvested the previous year \$1500 worth of honey. In the forty years that he had kept bees in connection with a large farm the bees had always paid better in proportion. This man had become the "skilled mechanic." He began with bees on a small scale, and increased as he gained in knowledge by practice and reading.

Some time ago a lady asked the editor of a bee-journal if she and her daughters could make a living by keeping bees. She said they would like to go to the country in the good fresh air to escape the headaches she had when sewing in a densely populated city. Apparently she knew nothing about bees, nor had the slightest idea that some theoretical knowledge should precede the practical. Judging from this I thought to myself that she had better leave beekeeping alone, and remain with the work she was accustomed to—for the present at least.

I have kept bees for the last twelve years as a side line for pleasure and profit, and have had more or less success—enough, at least, to urge me on to greater efforts. Before I ventured into the business I lived in the city proper, although always a lover of nature. When very young my father lived in the country on a small farm, and perhaps I inherited this love of nature at an early age.

Before I kept bees I had never seen a bona-fide bee-hive until an intimate friend became interested and purchased two hives

Henry Reddert's suburban apiary, Cincinnati, Ohio.

from a beekeeper. He invited me to visit him; and when I did so my love for rural scenes all came back. I watched his bees coming in and going out of the hives for hours at a time, and I concluded to have some myself. I sent to the public library for a book on beekeeping. The first I received was written by Huish, an English writer. As it was written in 1817 the pages were yellow with age. Next I read Langstroth's "Honey Bee," then Quinby's "Beekeeping," and in addition I subscribed for two bee journals. This reading kept me busy for two years. I made two hives on the Langstroth pattern in the cellar of my home, all the while happy in the thought of my future venture. I read bees, thought bees, dreamed of bees, and awoke in the morning with bees buzzing in my ears. I certainly had the bee fever.

My next thought was to get a suitable location in the suburbs. My text-books and bee-journals had advised me about this, and I finally found one. My new home was surrounded by elm and poplar trees, with a few peach trees, a fine lawn, and acres of white and sweet clover all around. Here I took care of my two colonies, which I purchased from a go-as-you-please beekeeper, to the best of my knowledge and ability. I became interested in the beekeepers' association, and made many beekeeping friends.

During the last 12 years I have failed to get a crop but one year, when a very long drouth almost burned the clover out of the ground. My family is fond of honey, and now that we produce it ourselves we use plenty of it. The surplus we sell at a fair profit. We are all in good health, which can not be measured in dollars and cents.

The photograph shows a part of my apiary. The fence on the north side acts as a

windbreak so that my winter losses are reduced to a minimum.
Cincinnati, Ohio.

AFRICAN BEES STING BLACK WORSE THAN ANY OTHER COLOR

BY W. G. DAVIS

Here in South Africa, where beekeeping is still in its infancy, a good many bee-owners still persist in keeping bees in the old-fashioned way. Barrels, boxes, and, in fact, any thing in which bees will live,

are used for honey production. When I say bee-owners I do not mean beekeepers, for all bee-owners are not beekeepers. The majority of these, when they start taking the honey, cut out the brood and discard it, and take the honey. There is always a certain amount of honey allowed to be about, and

A BUNCH OF WHITE LEGHORNS AND THEIR KEEPER.

Dear Mr. Root:—I have read Mr. Root's many articles in GLEANINGS relative to his chickens, and have often wondered if he has tamed his as I have mine. The enclosed photograph is a picture of a bunch of White Leghorns we raised last summer, and myself.

Denver, Col., Jan. 15. MRS. LOUIS F. JOUNO.

W. G. Davis, Johannesburg, Transvaal, S. A.

the result is that the neighboring bees start robbing, and the trouble commences. Many head of cattle, poultry, etc., are lost every year through the carelessness of these so-called beekeepers. When this happens I am invariably called to attend to the bees, and I am sure I could relate a score of instances where the bees have done considerable damage.

The first time I was called I had on a black suit of clothes; and when I arrived at the scene of destruction the bees immediately set about stinging my clothes, and I am sure that there were hundreds of stings on the clothes when the bees were eventually quieted. Among the stock lost were black pigs and fowls, and also a black dog. On returning to my home I thought it funny that a buff-colored dog on the premises did not have a single sting on it, and I resolved to try an experiment on a future occasion. The opportunity was not long in coming, for a week later I was informed that a swarm of bees had gone on the rampage and killed a lot of poultry and a valuable cow. I took with me my new outfit—a khaki-colored suit and veil which I had specially made. On arrival at the scene there were 29 fowls, 2 turkeys, and a black and white cow lying dead. The bees were then stinging something awful; and although they had stung to death the above-mentioned stock, they did not attempt to sting my clothes or veil, although my assistant, who had on a black veil, received

a good many stings on his neck. There were nine Buff Orpington fowls in the yard with the others; and after the fray I examined those fowls thoroughly, and could find only three stings on those buff fowls, while those that were dead were literally covered with the stings. I have since used the outfit on a number of occasions, and found the bees never attempted to sting me when I had it on.

I submit this experiment to your readers for consideration. I feel sure they will quite agree with my remarks. There is one great drawback about a buff-colored veil; and that is, it is almost impossible to see the eggs in the cells when examining the frames of a bar-frame hive; but for special emergencies as above, I commend it to your readers for a trial.

Why do bees sting black? Why do we look askance at any thing that is foreign to us? There are not black flowers for the

A GLIMPSE OF OUR FLORIDA DASHEENS.

As the above picture was taken, as nearly as I can make out, some time about the first of July, the dasheens are very much larger just now, Aug. 5. The picture gives you a little glimpse of some of the Florida pine trees and other vegetation that grow on our five acres.—A. I. Root.

Sprig of pine covered with vegetable honey-dew. The leaves that glisten are fairly varnished over with the sweet secretion.

bees to work on, and black is consequently foreign to them, while, on the other hand, there are plenty of yellow and white flowers that they are constantly working on, hence their frenzy to sting the former color. I notice you mention the interior of the hive is black; but I think you will alter your opinion when I tell you I was locked in a dark room for 18 months with an eye trouble, a few years ago, and the only light in the room was admitted through an aperture not more than $\frac{1}{8}$ of an inch in diameter, and I can assure you that, after a week, I could discern every article in the room, and find my way about; therefore I say the hive is not totally dark or black.

Johannesburg, S. Africa.

HONEY-DEW ON PINE

BY J. C. BALL

I am mailing under separate cover some twigs of pine covered with honey-dew that I thought might be of interest to you. The honey-dew, I think, must have been caused by a heavy frost just after a very warm spell. I am sure it is from the pines, because there are no trees near but pines, and, besides, the other trees have not budded out yet. It is very seldom that it is seen on pines about here. Some seem to think that pines never have honey-dew. This has been on the pines about a week, and the ground is well spotted with it. Sometimes it hangs in large drops on the twigs.

Kinsale, Va., April 15.

[The above letter was sent to Prof. H. A. Surface, Economic Zoologist of the Department of Agriculture, Harrisburg, Pa., whose reply follows.—Ed.]

I have received and examined the sprig of pine from J. C. Ball, Kinsale, Va., and I find considerable honey-dew upon it. I find no plant lice nor scale insects, and must say that either some insect of this kind was present on the trees above these limbs and dropped the honey-dew upon them, or this came from glandular exudations of the pine tree, which is possible. In fact, upon careful microscopic examination of the specimen at hand I must say that there is no evidence that the honey-dew originated from any other source than directly from the bark itself without the intervention of insects. Internal glands will secrete sweet liquids of this kind.

H. A. SURFACE, Economic Zoologist.
Harrisburg, Pa., April 15.

LOCATING APIARIES CLOSE TO THE MAIN SOURCE OF NECTAR

BY LOUIS H. SCHOLL

There is quite a diversity of opinion regarding the proper distance apiaries should be located from each other. I have been an advocate of smaller apiaries, located close together, for many years. My own apiaries contain 50 colonies each, and are scattered over the country, three and many two and a half miles apart. This way I get a good distribution and more evenly distributed

foraging of the bees. The loss of time caused by many bees foraging over the same ground near a large apiary, and others having to go a great distance from home, making honey-gathering less profitable, does not exist with my system.

There is considerable doubt in my mind about bees going any great distance, under ordinary circumstances, to gather nectar. The accompanying drawing of a number of my former locations may be of interest. Apiaries marked A and C are located at the edge of what we call the mountains or foot-hills. The mountainous country is suited for honey crops only in the most favorable years, and these have been far between the last few years. That made my observations of so much more value, and the evidence was the more apparent.

On the other hand, the apiaries marked B and D, in the black land farming and mesquite country, which is well suited to beekeeping, have done very well year after year, and produced good average crops. It will be noticed that these yards are only $2\frac{1}{2}$ miles from the other yards, even a little less in one, and that the distance to the edge of the foot-hills is only a little over two miles.

The two yards last mentioned outstrip the others every year, and the two yards just on the divide do not do nearly as well. It will be noticed that the distance is not great enough, it would seem, to make any material difference. Our own experience teaches us differently.

The apiary marked E, located two miles from the edge of the foot-hills, was in the mountainous country where enough forage plants for the bees abounded in this immediate locality to enable the colonies to build up to strong and even powerful colonies during the spring; but when the honey-flow came in the lower black-land country, only a few miles away, they would be on the

verge of starvation if forage was scarce nearer the apiary. We had to move this yard into the farming and mesquite land country, and since then they have done well.

If bees do go long distances to gather nectar, the yards that were located in the mountainous country should have done better than they did, especially those at the immediate edge, or on the divide. But those located away from the above territory, although only a few miles, did so much better every year that we have moved nearly all of our apiaries into this better territory, and are contemplating moving the few others also. This is pretty strong evidence, and I can vouch for its truthfulness.

New Braunfels, Tex.

REPORT OF ANNUAL CONVENTION IN NEW ZEALAND

BY E. G. WARD

The third annual conference of the beekeepers of New Zealand was held in Wellington June 18, 19, 20, and was well attended. A number of instructive papers were read, which were contributed by leading men from all over New Zealand. The conference was fully reported, and the proceedings will be printed in pamphlet form, and will include the papers contributed. This will form a permanent record, and be of great service to absentees in that they will be able to take advantage of the ex-

periences and instructions appearing. The New Zealand government has contributed \$50.00 toward the cost, and representations were made to several of the cabinet minister which, it is confidently hoped, will result in a number of extremely useful reforms being provided for by legislation at next session of parliament. Among these are compulsory registration of apiaries; compulsory grading

of honey, and regulations dealing with carriage of bee material.

The conference was opened by the Hon. R. H. Rhodes in the absence of the prime minister, who is minister for agriculture, and who is a leading agriculturist himself. Up till the present conference the industry has been in a rather disorganized state; but a new constitution has been adopted, and it

is now hoped that matters will go on smoothly.

The previous year's report showed that the late executive had established an export honey trade, and the product is being shipped partly to England and partly to Vancouver. As the honey shipped had been government graded, the quality could be vouched for; and as only the best had been sent, the confidence of buyers would be gained as it was graded and stamped by the Agricultural Department officers.

A good deal of discussion took place as to the relative value of fostering local markets or encouraging the export trade; and opinions were fairly evenly divided between the two.

A good deal of discussion took place regarding the value of advertising to increase local consumption. Many speakers contended that, if systematic advertising were done, there would not be any need to export. On the other hand, a strong section of those present, including Mr. T. W. Kirk, Director of Orchards and Apiaries Divisions of the Agricultural Department, contended that, if the export trade were pushed forward, the local market would take care of itself. The speakers instanced the success of the dairying, meat, and fruit industry, in support of their contentions, and, if any thing, were in the majority.

The incoming executives were instructed to consider the question of co-operation, and report in six months.

At the close of the conference an address was given by Mr. Lyman, on the export of produce to the west of England. The scheme was explained fully, and keenly discussed afterward.

A number of samples of honey were sent in by beekeepers from all over New Zealand, and these were graded by the officers of the department, and a report attached. This was an education to those present; and as it is the intention of the department to issue regulations very shortly, dealing with the handling of honey from the hive right through to the bottling for home trade or packing for export, there will be much information for those interested in a concise form.

The name has been altered, and the business will be carried on along somewhat different lines than formerly; and it is believed that the new constitution will consolidate the beekeepers and include all the existing associations as well as the individuals under a large association, somewhat on the lines of the National in America. The name adopted is the National Beekeepers' Association of New Zealand. A vote of thanks to the retiring officers and honorarium to

the Secretary were passed, and the conference of beekeepers of New Zealand for 1913 closed.

Christchurch, N. Z.

MY EXPERIENCE WITH THE STEAM KNIFE AND HONEY-PUMP

BY MORLEY PETTIT,
Provincial Apiarist, Ontario, Canada.

Since the advent of the use of power for running the honey-extractor, the two most important improvements along this line that have been made are the steam uncapping-knife and the honey-pump. The steam uncapping-knife consists of an ordinary uncapping-knife with a copper jacket placed over the flat surface, with a steam hose attached near the handle, and a small hole for the exhaust at the point. A copper boiler holding about four quarts of water, placed on a coal-oil stove, supplies the steam. It has a screw cap for filling with water, and a nipple for attaching the hose from the knife. The hose is about three feet long and $\frac{1}{4}$ inch in diameter.

The first time I undertook to use this knife I had an old coal-oil stove with one flat wick; and after waiting an hour or so to get up steam I found that it would not generate pressure enough to be of any use. We then secured a blue-flame oil-stove with an asbestos wick. In operation I find that the more steam pressure we have the better results, because the hotter steam is dry, and does not cause so much drip from the point of the knife. For the best work I find that there must be a good strong jet of steam coming from the point of the knife all the time. The regular steam uncapping-knife is of the Bingham style, with the broad trowel-like blade. For my experiment I asked to have a steam-jacket placed on one of the Jones knives. When it reached me I found that the blade was shorter than I had suggested. The blade is only about $8\frac{1}{4}$ inches long whereas the Langstroth frame is $9\frac{1}{8}$ from top to bottom; and to get the best work from an uncapping-knife it must be long enough to reach clear across a Langstroth frame with at least an inch to play on for slanting the knife or giving it a sawing motion. So, although I have not had a chance to try it, I am sure I could do much better work with a steam uncapping-knife having a blade $10\frac{1}{2}$ inches long. Up to the time I tried the steam knife the best knife I had been able to secure for rapid uncapping with Langstroth frames is a knife with a straight blade about $\frac{1}{8}$ inch thick at the back, $1\frac{1}{4}$ wide, and $11\frac{1}{2}$ long from the handle. When combs are well bulged, and

the operator has a strong wrist, he can uncapp one side of a comb with one long steady stroke.

It has always been a puzzle to me why beekeepers who are anxious for just such a result in uncapping will so often reduce the width of a few thousand combs instead of adding a couple of inches to the length of two or three knives. Now, if a long blade is good in a cold knife, how much better it would be on a knife that is heated with steam! However, my experience with the steam knife teaches me that in any case a heated knife is very much better than a cold one, especially if the combs are stiff and the honey cold.

Ever since I first learned, several years ago, that some one was using a pump in connection with a power extractor for taking the honey from the extractor, I have been anxious to give it a test; but reports from those who tried pumping honey last year were not very favorable. At the convention at Amherst, Mass., in June, Mr. E. R. Root demonstrated the honey-pump sufficiently to my satisfaction to persuade me to give it a trial. He took 200 pounds of thick cold honey and pumped it from the extractor, raising it about eight feet, and conducting it about ten or twelve feet horizontally. The pump works on the rotary principle, and is connected by means of a belt with the cross-shaft of the extractor, a pulley wheel being placed on the outer end of the cross-shaft. The instructions given with the pump indicate that it is to be connected by means of a rubber hose with a special opening in the side of the extractor; but not having a tinsmith handy, and wishing to avoid cutting a hole in the extractor-can, we took a longer piece of rubber hose and brought the end of it around to the regular gate of the extractor-can, wrapping it with paper to make it fit snugly in the opening. It took considerable experimenting to get every thing to work satisfactorily. First, it seemed to me that the pump would be less in the way if it were back near the engine; so a longer piece of hose was used for conducting the honey from the gate around to the back of the extractor; but when the pump was in operation we found that the friction in the longer hose caused the honey to travel so slowly that the hose was not able to resist the suction of the pump, and collapsed, flattening out so as to interfere very much with the passage of the honey. The pump was then moved up to the front of the extractor, near the tap, and a shorter hose used. Still there was trouble because the hose was not strong enough to stand up under the air pressure; so a stronger piece of hose was

put on, and there was no more trouble from that corner. For conducting the honey from the pump to the storage-can we used about 20 feet of ordinary one-inch rubber hose, fastening it up with cords to be out of the way. We found that, when the honey was cold, the pump would not raise it to the height of nine feet and force it along through that length of pipe; but by lowering the hose to a height of about seven feet from the floor it worked very well.

Another source of trouble was the slipping of the belt on the pump; and it seems to me it would be much better in sending out a machine to the general run of beekeepers to send a pulley-wheel with flanges, which would keep the belt from coming off when the alignment and tension are not exactly right. We placed a little honey on the belt, according to directions, and found that that worked well when just the right quantity was used; but a little too much caused the belt to slip off.

The first thing in the morning we found that the honey which had been smeared on the belt the night before had collected moisture, and was so slippery that the belt and pulley-wheels had to be very thoroughly wiped dry before they would work. The honey-pump, like any other machine, requires a certain amount of attention, and is for beekeepers who are adapted to handling machinery; but neither it nor the gasoline-engine requires any more skill than the multiplicity of machines that are used in all farming operations at the present time.

The first half-day that I operated the steam-knife and pump I was able, working alone, to uncapp and extract about 1100 pounds of honey, practically all of which was cold, and mostly capped. While this was not a large record, still it was good for the first half-day with the implements.

Another suggestion would be to attach the pump direct to the engine or shafting, and not to the extractor. Having the extra load delays considerably the frequent starting of the latter after changing combs. In spite of details which need improving I would not care to handle a crop of honey without the help of the steam knife and the pump. I don't see how I ever got along all these years without either. I don't intend to be without them in the future.

The next improvement most urgently required is a hot-water jacket on the extractor, connected with the water-cooler of the engine. By using this the honey could be pumped more easily, and would strain readily through a strainer placed on the store-can.

Guelph, Ont., Canada.

[Referring to the flat-wick oil-stove as mentioned by our correspondent, we have found that it is really necessary to use a blue-flame stove in order to furnish enough steam to keep the knife hot when it is imbedded in the cold honey, as is the case when uncapping bulged comb.

If an oil-stove is used, care must be taken to see that the asbestos ring which takes the place of a wick is not covered with carbon; otherwise it is difficult to control the heat, and under such conditions the valve must be opened so wide to keep the stove burning at all that entirely too much flame strikes the boiler, with the result that the steam blows furiously from the end of the knife, and the water in the boiler is evaporated too quickly. A gasoline-burner can usually be controlled rather easier than an oil-burner. With the proper control of the heat, three quarts of water in the boiler will run the knife half a day.

There has been considerable difference of opinion in regard to the length of the blade of the knife. With combs that are bulged, there is no doubt in our mind but that a long blade is an advantage. With combs that are rather closely spaced, so that the surface is depressed in places, the shorter blade seems to be handier. We ourselves prefer a blade a trifle shorter than the width of the comb. With a sawing motion the cut is easily extended the entire width of the comb, and then when a comb is to be uncapped, the surface of which is depressed somewhat below the top-bar, the shorter blade comes in handy, for it can be tilted slightly, and works down into the depressions easily. However, much depends upon the manner of using the knife.

For best results in using a honey-pump, the shortest possible length of pipe must be used between the extractor and the pump. A long pipe creates so much friction that the honey does not run by gravity to the pump fast enough. The pump will not deliver honey to its full capacity unless the honey runs to it by gravity as fast as the pump can handle it. For this reason the pump should be a little lower than the opening into the extractor, and the tube should be as short as possible. Moreover, the tube must not show any tendency to kink, as this reduces its capacity.

A rubber hose is not to be advised for conveying the honey from the pump to the tank, for it is difficult to prevent it from kinking slightly at the points where it is supported, thus reducing the capacity of the hose and causing a back pressure on the pump.

Probably it would be better to use a flange pulley on the extractor shaft; al-

though if there is a decided tendency of the belt to slip off, the flange pulley will not overcome the difficulty, for the edge of the belt would ride the flange and in a short time ruin the belt. If the pulleys are lined up properly, and the pump located so that the belt will remain tight, there is no trouble with slipping. Occasionally a piece of old tough comb broken off, or a chip from a broken end-bar or top-bar will find its way into the suction pipe, and finally into the pump. This will cause the pump to stick momentarily, throwing off the belt. It does no good to attempt to put the belt on immediately, for it will only come off again. The pump should be worked backward a revolution or two with the hand, then forward and backward a few times until the obstruction is finally broken and carried through the pump. Great force should not be used, as there would be danger of injuring the pump. It is only occasionally that this happens.

A very little honey on the belt is all that is necessary, a drop or two at a time being sufficient. If there is any accumulation of honey on the belt and pulleys it does more harm than good, as our correspondent says. Only a great accumulation would absorb moisture from the air, and make trouble the next morning.—Ed.]

Caging the Queen in a Cage of Perforated Zinc to Prevent Swarming

Dr. C. C. Miller:—In June 15th GLEANINGS you gave your method of controlling swarming. I will just tell you how I do it out here. When there is a likelihood of the bees swarming, the strongest are examined for queen-cells. If any are found they are destroyed, and the queen is caged for ten days on the top-bar in the same hive. On the tenth day make an examination for queen-cells. If any are found they are destroyed. Raise the cage and liberate the queen; ventilate the hive by raising it three or four inches off the bottom. If supers are on, ventilate by shoving one forward and the other backward so as to leave a space of $\frac{1}{4}$ or $\frac{3}{8}$ of an inch. If the queen is old, kill her and allow one of the cells to hatch; or a select cell, if any is on hand, is given. If not, instead of liberating the queen kill her and introduce a young queen.

A piece of perforated zinc is the material of which the cage is made. Bend the edges so as to bring it into a trough shape. Press it on top of a frame; raise one side about $\frac{3}{8}$; catch the queen and put her under and press down. While she is there the bees won't build any more cells unless the queen lays in them, which she can not do, being caged. That is the way it works out here. Perhaps there is a difference over on your side; but there might be some variation to make it work.

J. E. THOMPSON.

Halfway Tree, Jamaica, B. W. I., July 7.

Dr. Miller replies:

This is interesting, and much the same as things are done here. The cage is quite ingenious; but with the queen caged I should expect my bees to start cells in many if not most cases. To be sure, the queen can not lay eggs in queen-cells; but the bees can start cells with worker larvae.—C. C. MILLER.

Heads of Grain from Different Fields

Honey from Diseased Colonies; Rendering up Foul-broody Combs

I wish you would be so kind as to give me the following information: Do you think one is liable to contaminate healthy colonies of bees by the use of supers and fixtures in the production of comb honey that have been used over colonies having American foul brood—that is, if frames, supers, and slats have been used over colonies, using new sections and starters in the supers? Do you think comb honey produced over a foul-brood colony has the germs of foul brood in them? Do you think it is necessary to char or scorch the super boards used over foul-brood colonies?

I should like information as to the best method of separating honey and wax from diseased brood-combs. I have no extractors or wax-press, but have a fruit-press.

Pittsburgh, Pa., July 30.

G. L. CRAIG.

[As a general thing it is wise to err on the safe side. Any thing that has been in contact with a diseased colony, especially combs or honey, is liable to convey the disease if it is placed over or in contact with a healthy colony. We say *liable*. We do not mean by that that it is *sure* to do so; but it has been customary on the part of producers to sell honey produced in sections or extracting-combs that came from colonies having disease. Whether the practice will be prohibited some time in the future we do not know. Honey from a foul-broody colony will not affect human beings; but the danger is right here: If the housewife or maid does not burn the sections after the combs are cut out, and if she throws those same sections into the garbage-can or into the back yard, the chances are that the bees in the vicinity will help themselves to the honey drip, and thus carry the infection to their hives.

Yes, comb honey produced over a foul-broody colony may have the germs.

It is advisable to scorch the inside of hives, supers, and super-boards, not enough to char, but just enough to blacken the wood that has come from infected colonies. Our experience has shown that such hives and hive parts may transmit bee disease. Some 25 years ago we were unable to clean up foul brood where we shook back into the same hive; but we had no trouble after the insides of those hives were scalded out or scorched out. If you have combs which are infected with foul brood they should be removed from the hives, and frames of clean foundation should be put in their place. The old combs should then be extracted, and afterward melted up in a wash-boiler containing hot water. Fork the mass out with a stick after the combs are melted. When you are through, burn the frames or subject them to a further treatment in boiling water. But we would advise you to destroy them, as the hot water has a tendency to spoil them.

The wax may be dipped off from the surface of the slumgum. But a much better way is to cut the combs out of the frames, put them in a burlap sack, and weight them down under hot water. The sack is then punched with a stick to break the combs and free the wax. But such a method of rendering is very wasteful; and if you have very much of it to do, you would save money by buying a regular wax-press. The fruit-press you have would not be heavy enough nor strong enough to squeeze the wax out of refuse comb. When wax brings from 30 to 33 cts. per lb. it is well to get as much of it as possible. If you have only four or five colonies the wash-boiler method may be good enough for the time being. But when through with the work be sure to clean every thing thoroughly; and the honey that is extracted should be sealed at once in metal or glass cans. To render it free from danger it should be heated over a slow fire for at least twenty minutes

—that is to say, it should boil for that length of time. But such boiling will generally spoil honey for purposes of marketing; and we should be afraid to give it back to the bees for fear of starting disease again.—ED.]

Some Observations upon Winter Cases and Moisture

During the discussion of a paper relating to wintering, which I had the honor of reading at the annual meeting of the New Jersey Beekeepers' Association, on Dec. 20 last, some light was thrown upon the question of how the moisture in the hive is disposed of under a sealed cover.

I assumed that the hive walls are always colder than the atmosphere in the hive, and that, consequently, moisture is certain to condense thereon; and if the wall surface is waterproofed, the water of condensation will run down and out without further harm. I also stated that water trickling from the corners of the hive entrance is sufficient evidence that things are operating in accordance with my assumption.

These propositions looked good until Mr. C. H. Root, of Red Bank, who is probably the largest practical honey-producer in the State, asserted that he "never had any water coming from his hive entrances," and then asked, "How is the moisture disposed of in such a case?" This was a poser until Dr. Phillips gave the solution by saying "the moisture is *not condensed*, but remains suspended in the atmosphere as vapor, and passes out by way of the entrance in that form, the inside of the hive being maintained at a temperature above the dew point," which is the degree at which condensation takes place.

Now, it is plain that such a condition is exceptional; but having seen Mr. Root's winter-hive cases I began to realize and appreciate their value and effectiveness. They are certainly more effective than any double-walled hive so far brought forward.

In the matter of winter protection, first cost may decide what method to adopt; but within reasonable limits it may be wiser to consider effectiveness in the long run as an offset to first cost. I can not state the cost of these cases; but it must be considerable. They, however, last for years, and render full value every season. Mr. Root stated that he may lose in winter one, two, or three colonies among the 300, more or less, which he has. This is certainly a most remarkable record, and no stronger endorsement of his method could be desired.

A somewhat similar winter case was described and illustrated in GLEANINGS for Jan. 15, 1908. Briefly described, Mr. Root's case is made 4 to 6 inches deeper than a hive-body, and without top or bottom. It has double walls four to five inches thick, outside measure, and is packed with planer chips or sawdust. It telescopes down around the hive-body closely, and rests upon the hive-stand. When so placed the vacant space above the sealed cover on the brood-nest is packed full of leaves, and a regular hive-cover is put on. Suitable provision is made in the case for the entrance. During the summer these cases are stacked up out of the way, with a hive-cover on top.

The advantage of such winter cases lies in the fact of keeping the hive so very warm that positively no moisture condenses anywhere, and consequently no harm is done. Everything considered, it appears there is in winter never any danger of keeping the bees too warm out of doors. Then there is the other advantage that there is no heavy or clumsy encumbrance of the hive as with the permanent packed double hive. Having operated a season with hives having double walls 2 to 3½ inches thick, I appreciate the greater convenience of the single-walled

body, which can be exchanged or reversed, and used either as brood-nest or super without the necessity of transferring frames.

Where lumber is cheap, and the beekeeper is handy at woodworking, these cases would be less expensive; and, once provided, would be always ready for winter preparations with the least fuss.

Bees, in the hive where conditions are comfortable and agreeable, will not fly out when the sun shines if the temperature is not right. On the other hand, if there is no effectual arrangement for keeping the hive so warm and so comfortable, then things are different, and dampness must be reckoned with.

New Jersey.

Visit of Dr. Phillips to Porto Rico; 1000 Pounds from One Colony

The readers of GLEANINGS, perhaps, would like a message from Porto Rico. The most important event which has taken place in our life as apiculturists has been Dr. Phillips' visit to this island. He landed on the 29th of May, and was the guest of my good friend Mr. Van Dine, entomologist of the experimental station of the Association of Sugar Producers of Porto Rico.

On the following Sunday he visited my apiary, and spent a few hours in my home. He questioned me, among other things, about the production of honey, and was much surprised when I told him that the average output per colony was from 240 to 300 lbs., but he was able fully to realize the truth of my statement during his visit round the island, when at one of the many fine apiaries he was told by the owner, Mr. Mejia, that one colony had produced 1000 lbs. of honey. What do you think of that?

On his return there was a conference in the assembly hall of the University of Porto Rico, which was well attended. Limelight pictures were used. Dr. Phillips thinks that this is an ideal place for beekeeping, as we have no bee diseases of any kind. But one great obstacle in the way of beekeepers is ignorant competition; and as a proof of what I say I shall cite the fact that, in the city of Ponce, when the town council gave orders that all hives were to be taken out of town, one thousand colonies belonging to different owners were moved. This island is very small and densely populated; and if the bee fever continues as it has begun, Porto Rico will soon be overstocked with bees.

V. A. TEXERA.

Rio Piedras, Porto Rico, June 27.

A Woman who would Rather Work with Bees than to go to Pink Teas

I now have 24 colonies in the cellar, and do all the work myself except putting them in and taking them out, when my little girls help. It is a rather awkward job, as we have no way of getting them in except down through a very small trapdoor in the floor. We accomplish it, however, by taking away the stair steps and letting the hive down by ropes attached to the four corners of a box end of the right size. We take them up the same way without the assistance of a man at all.

I love every branch of the work (with the exception of wiring frames). Can't some man devise a way that is easier than that? The carpenter work I like very much, and I have always regretted not being a boy, for the reason that girls can not very well be carpenters. Nailing up hives and frames satisfies the longing. It is clean work handling and putting together the fresh beautifully cut wood.

I can truthfully say that nothing in beekeeping is impossible to a determined woman except, perhaps, climbing a tall tree, which is the only time I ever need the assistance of the men, and that is not very often, as I clip the queens. Never shall I for-

get the first one I found after two or three days of searching in a very populous colony. My fingers trembled so that I was afraid I should squeeze her and kill her before the wing was clipped.

I have found that beekeeping is an ideal occupation for women, as they must be so much in the open air. Some of the work is heavy, of course; but one can do it. I weighed only 101 pounds three years ago, when I first got my bees; but I now weigh 120, and am not nearly so nervous and weak. Manitoba has a very short honey-flow, as we can not put the bees out till May 1; but most years there is a very good crop from the wild clover and other flowers. Two years ago I dedicated one of my eight colonies to the church to help pay the minister's salary. That hive gave me four supers of one-pound sections. It was a good one; but some of the others did almost as well.

The summer months here are so very hot that we have a great deal of swarming; and as our present cellar will not accommodate more than 25 colonies (by tight squeezing at that), could some person tell me a plan to keep them down to that number? Could I unite them some way? After practicing the shaken-swarm plan I shall have 48 or more. As they sometimes cast a swarm from the new one away on in August, I wish to keep all the bees.

I would rather hive a swarm than attend the pinkest of pink teas or go to a ball, and I am very fond of society too.

MRS. Y. N. WESGATE.

Portage la Prairie, Manitoba, Can., July 4.

[By shaking the second time, after three weeks, you get the rest of the bees in the parent colony into the new hive with the swarm. In this way you can keep down increase if you desire.—ED.]

Smashed Combs in a Bee Tree

About ten days ago I cut a bee-tree on my farm three miles from Hicksville. This colony contained a million bees and a barrel of honey. It filled the hollow in an oak for a distance of nearly six feet, and the diameter inside is 14 inches. We cut out the log and found the combs at both ends in good condition. We nailed it up and hauled it on some hay bedding to Hicksville, where, with great triumph, we set it up. The first day after, there seemed to be a large number of bees; but on the days following they were very quiet, and honey began to run out at the bottom of the "gum" as we call a hollow tree out here in the woods. Two days ago we took it down and sawed off a piece from the upper end, where we found every thing all right. When we opened the lower end we found it a mass of smashed comb and dead bees. We dug out two bushels of comb loaded with honey. We left a foot of the comb in the upper end, which is intact, but has a little honey. I found no eggs in the empty comb. I feel quite sure that the queen perished.

Hicksville, Ohio, July 21.

J. H. DIEBEL.

[From the general description given in your letter of July 21 it is evident that the combs broke down in the lower portion of the log hive probably during the time that you moved it. When you set it up these smashed combs fell down upon the bees, killed the brood and bees, and finally the honey began to run out at the bottom, as you describe. It is not at all certain that you have killed the queen, but there is a possibility that this may be the case.—ED.]

New Zealand Beekeepers Organize Under a New Constitution

The beekeepers of New Zealand have organized under a new constitution. The meeting was attended by nearly all of our leading beekeepers—some 7000 colonies were represented by their owners. The general feeling is that it was good to be there.

Wellington, N. Z., June 20.

R. N. BRIEKELE.

Our Homes

A. I. Root

Cast thy bread upon the waters; for thou shalt find it after many days.—Ecc. 11:1.

WATER FOR BEES WHILE BEING SHIPPED BY MAIL AND EXPRESS.

Almost as soon as GLEANINGS was started, in 1873, I began planning for the shipment of queen-bees by mail; and I declared that a good serviceable queen should be sent by mail postpaid for an even dollar. But just as the new industry had begun to assume considerable proportions, owing probably to the work of careless beekeepers queens were ruled out of the mails by the Postoffice Department. Our good friend Prof. A. J. Cook, then of the Michigan Agricultural College, made a trip to Washington and interviewed the President, telling him of the importance of bee culture to the world, and the result was that queens were again permitted to go by mail. However, before traffic was once more restored a quantity of queens piled up on my hands, and I was for a time in a predicament.

With the above preface you will readily catch on to the following, which we reprint from GLEANINGS for September, 1878—35 years ago:

HOW TO KEEP EXTRA QUEENS ALMOST ANY LENGTH OF TIME; ALSO HOW TO GET OUT OF TROUBLE OF ANY KIND.

About the time queens were thrown out of the mails I was really in trouble—not for myself alone, but on account of the many that were sending me queens, and who were, perhaps, less able to stand the loss than myself. As soon as the order was received we dispatched postals to everybody who had been sending us queens, but for all that they kept coming. Day after day had I said, “Well, I really can not think we shall have any more; so keep up your courage, boys, and keep on dividing and making room for them.” We did so, but more kept coming. Hayhurst had just sent us a package of 25 or 30; Henderson had sent as many more; then Moore, of Atlanta, Ga., came in with a fine lot; and, besides the above by express, a lot of the A B C class were just getting the hang of the business, and they swarmed in at every mail, with their queer cages but nice bright queens until I almost began to be sorry I had ever taught them how to raise queens. Some of those that had been notified kept sending them in, saying they had nice queen-cells just hatching, and they must put the queens somewhere, and they thought I *sure* could get along with a few more.

One evening toward the first of August

our friend Charlie came in with another great bundle of queen-cages; and as I thought of the queens spread all around in the honey-house with every thing that we could think of given them, just to make them hold on to life a little longer, I am afraid I got into one of my ugly moods. It is nothing very strange, for I do have such moods, and am afraid I always shall, now and then. Said a bad “impulse,”

“Of course that fellow had received your postal card, and knew better than to send you those queens. I would send ’em right back, and let him bear the expense, to see how he likes it.”

But a better impulse said, “Steady, my boy; you are perhaps better able to take the shock of this event than many of your pupils, and you have no right to assume that they had received your notice. You have often said that calamities were sent on purpose to teach us useful lessons. Had you not better brighten up and grasp the situation squarely, and see what the lesson is that is to be learned?”

As I mused, I got into a better mood, and went upstairs around into the wax-room. The hands were all gone for the night, and it was still and quiet. I remembered how Mueller had asked God for every thing he needed for his work among the people, and it occurred to me that it could not be a wrong act to kneel down there and ask my heavenly Father to help me to be a better friend to those who entrusted their queens to me, and to ask him to tell me what to do with them, not only for my sake, but for the sake of all these bee friends all over the land. I did so, and after that I never borrowed any more trouble as to what I should do with the queens. I did not know at once what was to be done, but I felt as if some “old hand” were going to tell me just what to do, and so I looked cheerful.

I suppose I began to give the matter earnest study; but it seemed as if some one talked to me something as follows: The queen and bees, to stand long confinement in small quarters, must have clean, pure, fresh food. The honey that is used to soak the sponges often acquires a musty or sour smell in hot weather, and the bodies of the bees that come the longest journeys are often distended, especially after they begin to die badly. The candy made with flour answers nicely when first made, but after it gets dry and hard, the bees have nothing wherewith to moisten it, and so they die,

as you have so often seen. Cages prepared with fresh candy every day you send out bees might do, but this would be well nigh impracticable; for the cages could not well be used again, and those kept in stock or sold would endanger the lives of the queens, unless they were used at once. Honey mixed with the candy, although it answers well for short voyages, will never do for California and Texas, and the bees fed with it often have distended bodies, even when sent but short distances. Hayhurst's queens seem brightest and most natural, and his cages are probably filled a few at a time, and just before they are sent off. The experiments made with coffee or loaf sugar, years ago when the dysentery prevailed, seemed to indicate that it is a sure remedy for the distended bodies, and that as a diet it is more wholesome than honey. How shall we keep the candy from getting dry? Wetting it, just before being sent out, often daubs the bees, and answers for but a short time, even then. Putting in a sponge filled with water does better, but that will get dry and hard, even while coming from the Southern States, to say nothing of crossing the great dry deserts on the way to California. Some plan to enable the bees themselves to mix the sugar and water daily just as they need it, is what is wanted; can this be done? My mind wandered on a glass honeycomb; but the motion of the cars would shake the water all out. I thought of a large glass bead, with the water held in by capillary attraction; and, finally, I went into the drugstore and asked for some very small vials. They were out of half-dram, but had dram vials. I thought these too large, but finally took some, and soon had one filled with water with a groove cut in one side of the cork, that would just let a bee get his tongue in. It was placed over a ten-cent candy-cage, as shown in the right-hand cut below.*

As soon as I got it nicely fixed a friend sent three hybrids by mail. Although they had had a long journey, and one bee was dead already, they were given a bottle each and placed back of the typewriter. They found the orifice in the cork almost at once, and were very soon scampering about in the cage as lively as could be. They have been now caged in the same way ten days, and are as brisk and lively as one could desire. After it was settled that water and candy was all they needed (and I was surprised to find that a dozen bees would consume a dram of water in about ten days), the problem was how to fasten the bottle in the cage for shipment, so that it could

never shake loose, and yet so that it could be taken out to be filled. Our friend Will, who handles the queens, solved this problem by pushing a pin through the end of the cage and through the cork of the bottle, as seen in the cut at the left. The cage is represented with the wire cloth removed, to show the position of the bottle. The other end of the bottle is fastened by a pin set over it. As soon as it seemed to be a success, all the queens, both blacks and hybrids, of which we have a great quantity that have been shipped and stopped because no one will pay the express charges on them, were supplied with bottles of water, and not one has died since, where they had any kind of chance. They have been sent out daily, by express, sometimes as many as 20 or more a day, but not one failure has yet been reported. In one of the larger cages where the bees have been caged over a week, the bees clustered precisely as in comb-building; their bodies are small and natural, and yet they have consumed quite a large quantity of candy or sugar, and have had no fly at all.

Many of you have lost queens while caged and lying on the frames. Sometimes it was hard to explain why they died. We now introduce all our queens in these bottle cages, and have not yet lost one in them. One imported queen was lost; but, when examined, it was found that a cage had been used, by mistake, without any bottle in it. For sending bees across the ocean I would use cages with two bottles in them, placed with their mouths in opposite directions. If the cage should stand on end, so that the water was not near the mouth in one of the bottles, the other one would be just right. It makes me shiver to think of the poor bees I have probably consigned to death by thirst during these long summer days, simply because I knew no better. Hereafter the little fellows shall have all the water they wish; and if my invention should be of any use to the bee friends of our land, give God the praise, for it was given me in answer to prayer. A brisk trade is now starting up by express, and I shall probably soon want all the queens you can raise, if it be really true that we are to have no more losses in handling these wonderful little friends of ours.

Aug. 8, 1878.—The three hybrid queens have now been in the bottle cages 11 days, and are as lively as at first. To be sure that they had nothing but candy and water, I wrote to the friend that sent them, asking how he made the candy. This is his reply:

The way I make my candy is this: I put coffee A sugar in a new tin cup, and add water until, by mixing or stirring it with a paddle, every particle

* As the cut referred to is not readily available at this late date, and as it is not specially important, we omit it.

is wet. I then set it over a stove and heat until every particle of sugar is dissolved. When it is thoroughly melted or dissolved, remove from the stove and keep stirring it until it begins to cool or grain, then put it in the cages. M. G. KEENEY.

Quercus Grove, Ind., Aug. 6, 1878.

Aug. 12.—It is now over three weeks since the hybrid queens were imprisoned on the water and candy, and still they are alive and brisk. A few of the bees have died, but this length of time would suffice for a journey to California and almost across the ocean. As the bees in one of the cages seemed disposed to cluster as bees do in building comb, I have had a cage made of one of our section boxes, and supplied with sugar and a bottle of water in the same way. About 200 bees were put in, and the miniature hive stands beside my typewriter. Somewhat to my surprise, they commenced comb-building at once, and show no signs of wanting to get out. Perhaps we may get out an observatory hive for a parlor ornament, to allow the bees to fly, or not to fly, as we choose. Instead of glass, which is generally used, I would have the sides of a coarse-mesh painted wire cloth. This seems to annoy them so little that they do not act as if confined.

Aug. 25, 1913—35 years later:

I want you to notice particularly the second heading—"How to Get out of Trouble of any Kind." The above article came to mind just now because of the success our company is having by the use of water for shipment, not only by mail but by express, especially during the hot months of June, July, and August. At the time I made the discovery that the lack of water was the "missing link," I had copies of the above articles printed and sent out as advance sheets to the large number of friends who had been engaged in raising dollar queens, and I confess I was a good deal disappointed and perplexed to find this matter of water-bottles was for a time dropped, not only by other shippers, but by The A. I. Root Co. I still felt, however, that it *was* in direct answer to prayer; and when the matter came up again, 35 years afterward, I thanked God, because, after all these years have passed, it transpires that I was then *exactly right*. Ernest has told you elsewhere what wonderful success we are having, not only in mailing queens but in shipping bees by the pound all over the country. In giving place to the above, printed 35 years ago, I have been wondering how many of those whose names are there mentioned are still alive and keeping bees.

Later.—After having dictated the above, Ernest reminds me that we stopped using water in queen-cages because we found the "Good candy" answered so well that. by

general consent, the somewhat expensive and troublesome water-bottles were omitted. If the Good candy is freshly made, say the day the queen is sent off, and the distance is not too great, there is generally sufficient moisture, depending largely, of course, on the locality and the state of the weather. But for long shipments, and especially with bees by the half-pound or pound, or more, during hot sultry weather, water in some form, and in considerable quantities, according to the number of bees, seems *now* to be almost an *absolute necessity*. Let me refer again to that quotation of 35 years ago:

"HOW TO GET OUT OF TROUBLE OF ANY KIND."

The above indicates that 35 years ago I was getting into the habit (like George Mueller) of going to the great Father with all my troubles. Now, I am not sure that I have followed this up all through the past since that time; but whenever any real trouble has confronted me or mine, I believe I speak truly when I say that, sooner or later, I got off by myself and told the dear Savior all about it. A good many times what he pointed out looked difficult and hard; but when I followed the dictates of that "still small voice," peace, comfort, and happiness came. On page 467, July 1, a suggestion is made that I "ought to do an immense amount of good," if I have access, in the way I have described, to divine help in all emergencies. Without any desire to boast, let me submit the matter to my readers. Has not our journal, in the years that are past, to use that writer's own expression, done "an immense amount of good" to the world? If so, as I said 35 years ago, give God the praise.

A visitor called on us yesterday who is interested in growing alfalfa. He said a friend of his out west has secured this season 90,000 lbs. of honey. Bee culture alone has made great strides, and for this we are devoutly thankful; and if our journal has been also the means of helping righteousness, temperance, and purity to make tremendous strides I shall be more thankful still. Give God the praise. To go back to our opening text, let us not be afraid nor get weary in continuing to cast our bread on the waters of humanity. And let us remember the promise that we shall "find it after many days."

THAT "GREAT UNEXPLORED REGION."

The *Sunday School Times* for June 28 has been kind enough to comment as follows on my Home papers for June 1 and July 1:

We are liable to know some truths better by hearsay than by personal experience. A man who had

been exasperatingly annoyed by some town boys turned on them unexpectedly one day with a look so pleasant that they were quite taken aback. Then he spoke to them pleasantly. And then they stopped bothering him. Commenting on his own experience he said that "Returning good for evil is a great unexplored region." Yet most of us have opportunities for starting on an exploring expedition in that region almost any day. Suppose we investigate.

While reading the above it occurs to me that some of the meanest men I ever came

across have been redeemed and transformed by showing them kindness, and that you have not only forgiven but forgotten some past unpleasantness. I have seen such men made over. But right now, while I dictate, my conscience troubles me for using the term *mean* man. They used to be what the world calls "mean" and hard to get along with, but they have been transformed by the Christlike spirit.

High-pressure Gardening

HYBRIDS—THEIR SUPERIORITY THROUGHOUT BOTH THE ANIMAL AND VEGETABLE KINGDOMS, MANY TIMES, TO EITHER PARENT; SOMETHING ABOUT TOMATOES.

I have frequently mentioned my chickens in Florida that are a cross between the Buttercups and the White Leghorns. I made this cross, for one thing, to see if I could secure in this way more pullets than roosters. I also expected to get a better strain of layers and hardier chickens; and I think I have succeeded at least pretty well. Now, a very good friend of mine, Mr. E. C. Green, formerly of the Ohio Experiment Station, has made it his business for many years not only to test different varieties of tomatoes but to test crosses made from these varieties; and he has given the vegetable world, through the agency of our good friend W. Atlee Burpee, several of the very best tomatoes now grown. Well, last April, almost as soon as I arrived at Medina I went to our greenhouse and got six potted tomato-plants. Mrs. Root said that six would be ample for our small family. About two weeks after, I met our friend Green and he told me he would like to have me try a few plants of the new hybrids which he has been getting out. He brought me six, not potted, but just taken from the seed-bed. So we have twelve plants instead of six for our family. You may remember we had some severe frosts along the middle of May, and it was rather tough on the tomato-plants. It would have killed them all, no doubt, had I not covered them with pails and some boxes. I knew wooden pails would be better than metal; but not having enough to go around, I used one tin pail over one of the hybrid plants. The frost froze it down to the ground. The rest came out all right. But this one plant put out a sprout down close to the ground, and quickly caught up, or nearly caught up, with the rest. After the frost we had a week or two of cold winds and bad wet weather. The tomatoes all looked so sick that I did not expect much of them, but I began

to notice right away that the new hybrids seemed to be hardier than the pot-grown plants from the greenhouse. Well, these hybrids, although put out in the open ground two weeks later, bore the first ripe fruit. A little later Mrs. Root asked me if there were not some more tomatoes, and I told her I hardly thought there were. But I went out with a tin pan, got it full, and pulled off my cap and got that heaping full of great smooth purple beauties. I was surprised to find some of the handsomest had ripened up and commenced to crack open when they had been under foliage clear out of sight. This proved, as you may readily believe, one of my "happy surprises." I hastened down to my friend Green, and found he had pretty nearly half an acre of just such plants. Said I, "Friend Green, you are going to save a lot of seed from these nice tomatoes, of course?"

"Why, Mr. Root, I can not do it. These plants and the ones you have are the result of hand-pollination. In order to get this strain of tomatoes I was obliged to take the pollen from the Earliana and cross it with the pollen on the blossom of a Potato-leaf tomato, or something similar to the Potato-leaf. Now, this first cross, as you have noticed, is certainly superior to either parent; but if I save seed from these hybrids I shall have a mixed-up mess and nothing like the parent. This matter is pretty well recognized at our experiment stations, and is fully discussed in a bulletin I will lend you. The title is 'Bulletin No. 346 of the Experiment Station, Oneida, N. Y. Influence of Crossing in Increasing the Yield of Tomatoes.' Now you see that all of us who are growing tomato seed are up against an obstacle. This precious seed is obtained only by what is called hand-pollination."

Mr. Green here took his knife and showed just how he did it. He got some pollen on the point of the blade from one variety, and carried it directly to the blossom of another, and the fruit has to be watched

and taken from each blossom thus treated. The consequence is, such seed as this, every one grants, is superior, but it would cost too much in the item of labor alone to be sold at any thing like usual prices. He said he might be able to produce it for \$5.00 an ounce, or in small packets he might furnish 50 seeds for a dime. Now, I should be glad to pay a cent apiece for what seeds I need in order to get such plants as these I am describing. First, it is the earliest tomato I ever got hold of; second, it is almost of as good a shape as the well-known "Beauty" tomato; third, it is the most prolific of any thing I ever saw. Our tomatoes from these plants lay in heaps. They were literally piled up all around each one of the six plants. In the fourth place, it is about the hardiest tomato to stand frost and cold winds of any tomato I have ever had. And this, you know, is characteristic of hybrids, plants as well as animals. My hybrid Leghorn Buttercup chickens are certainly harder, more robust, and a little larger, than either parent. But the hybrids seldom if ever reproduce themselves exactly in the offspring. Poultrymen and seedsmen can explain this matter much better than I can. It has been discussed over and over again in regard to bees for half a century. The general agreement is, if I am correct, that the first cross between Italians and common bees will gather more honey than either of the parent races.

I persuaded friend Green to agree to furnish about 50 seeds of this hybrid tomato to the readers of GLEANINGS for ten cents. He will have the seed ready in a few days.

Of course the plant may be reproduced by cuttings instead of seeds; and I am planning now to raise a few nice plants from cuttings to carry with me when I go down to Florida in November.

THE NEW CELERY CULTURE.

A dozen years ago or more our good friend Greiner, who writes for our agricultural press, devised a new plan of growing celery in a back yard or garden, which he called the "new celery culture;" and he put out a book describing his new high-pressure gardening. We sold quite a few of them. Some people succeeded, while others, as usual, did not. But the book was well worth the 25 cents it cost.* It seems now that, after all these years, somebody has decided he could get some "dollars" by calling the idea something new. Read the following letter:

* The whole thing is now embodied, with ample illustrations, in Greiner's book, "Celery for Profit," which we have advertised and sold for many years for only 25 cents.

Mr. A. I. Root:—I am a short-term subscriber to GLEANINGS. I have a copy of your book, "What to Do and how to be Happy while Doing it." It was lent me by a neighbor. I read your articles in GLEANINGS under the head of High-pressure Gardening. I send you a clipping from *Suburban Life*. Do you know any thing of the book spoken of in the advertisement? Is it worth the price to a market gardener of limited means? It says \$50 from 5½ x 5½ yards, method simple, results sure. Do you think these statements are facts?

Gouverneur, N. Y., Aug. 4. W. G. BRAINARD.

Below is the advertisement our friend refers to:

NEW CELERY CULTURE; A LIVING FROM ONE-EIGHTH ACRE.

Nearly eleven hundred finest celery-plants may be easily grown on a rod square of land. At five cents per stalk, that means over \$50 from 5½ x 5½ yards. Two crops in one season. This new under-feed method grows extra-choice, crisp, and tender celery in eight weeks from planting. A fortune in your back lot. Method simple. Results sure. A boy can do it. Complete instructions, \$1.00. Free copies to Agricultural Colleges.

Montvale, Va.

MONTVALE FARMS.

As soon as I saw it I sent off a dollar; and what do you suppose I received? No book at all—just a single sheet of paper. It made me think of "The Natural Hen Incubator" that I have shown up several times. All there is on this single sheet of paper could easily be printed on two pages of GLEANINGS. You are simply to make a hot-bed and then put two loads of manure on a space 8 x 16 feet. This would be about the quantity of manure that market gardeners generally use for a hot-bed. Put a frame of boards on top of the manure and fill up with good rich soil. The author recommends poultry manure as one of the best things to make the soil rich. The plants are to be set out six inches each way. The bleaching is done by having the plants so close together (on very rich ground) that they bleach themselves, aided by tying up with a string. It is exactly the plan Greiner described in his book. Of course the ground is to be made very rich for this intensive cropping; and then you must keep it well watered if it does not rain. All this can be managed very well if one will take the time and pains. He says you can grow two crops of celery in one season; but I fail to see how two crops of celery are going to afford "a living from an eighth of an acre." You will notice there is no signature to the leaflet except the address, White Plume Celery Farm, Roanoke, Va.

I am going to submit the whole thing to the attention of the Postoffice Department.

SQUASH-BUGS AND—HOE-CAKES.

Dear Mr. Root:—I have just been reading your papers in GLEANINGS, and notice your article on moth-balls for squash-bugs, etc. I presume, of course, you have reference to the small striped beetle so destructive to young vines of squash, cucumber, etc. The remedy referred to may do the business all

right; and yet the one I wish to give you may go a little further toward reducing the high cost of living; besides, it is always on hand on the farm whenever wanted. It is as follows. Take an old bucket and fill it about one-fourth full of fresh cow manure. Fill with water, and stir. Apply direct to the plants. I generally apply by means of a bunch of tall weeds, which I take by the root ends, immerse the tops in the decoction, and shake over each hill. I have used nothing else for the last ten or fifteen years, and it has never failed to do the work to perfection. It is the smell that drives the bugs away.

As to Vice-president Marshall's hoe-cake to which you refer on another page, I think it is nothing more nor less than our corn bread, sometimes called hoe-cake from the fact that in earlier days the Southerners made a batter or dough, the main ingredient of which was Indian meal, which was spread on a hoe or similar instrument, and laid on an open fire to bake. This was called hoe-cake.

Berne, Ind., July 6.

M. BRENNEMAN.

Perhaps some of the friends may complain that our good friend Brenneman and myself are getting different things into rather close proximity; but you can stop a little and take breath after reading about the remedies for squash-bugs before you tackle hoe-cake. Yes, the remedy proposed will do the business. I have heard of it before, but had forgotten it. The only objection that we know of is that it is a rather disagreeable operation; but from the fact that it gives the squashes a fertilizer—that is, if you give them a good dose of the concoction, and at the same time it drives the bugs away—I think we can extend a vote of thanks to our good friend. Now for the other matter.

Very likely it is "corn bread" that Vice-president Marshall eats every day of his life. But where does he get it? Is such corn bread kept for sale by the bakers? If so, I have not seen it, and I generally make friends with the bakers wherever I am, and look over their stocks, especially the goods they furnish to "reduce the high cost of living." Can not somebody furnish us a recipe for making such bread as Vice-president Marshall eats "every day"? Corn meal is as cheap as common flour, and perhaps cheaper. Will friend B. kindly tell us how to make good wholesome bread out of golden corn?

THE DASHEEN, AND THE WORLD-WIDE DISTRIBUTION OF FOOD PLANTS RELATED TO IT.

The following, from our good friend Dr. E. F. Phillips, of the Bureau of Entomology, Washington, explains itself:

UNITED STATES DEPARTMENT OF AGRICULTURE.
Washington, D. C., July 29.

My Dear Mr. Root:—I am enclosing two quotations from Cook and Collins' Economic Plants of Porto Rico on "yautias," the Porto Rican name of the dasheen.

I saw a dasheen growing in a store window here to-day.

Sincerely yours,

E. F. PHILLIPS,

In Charge Bee Culture Investigations.

P. S.—Bulletin 6 of the Porto Rico Agricultural Experiment Station (Mayaguez, P. R.) is on yautias, or taniars, of Porto Rico. I think the Hawaiian station (Honolulu) also has one on taros as they are called there. E. F. P.

1903. Economic Plants of Porto Rico. U. S. National Herbarium. Vol. III., part 2, p. 264. *Xanthosoma*. Yautia.

Family Araceae.—In Porto Rico there are four kinds of taros, or "yautias," as they are there called. Three of them are species of *Xanthosoma*, a genus of aroids closely related to *Colocasia*, but having the leaves hastate—that is, the basal lobes are not connected behind the insertion of the stalk, as in *Colocasia*. The species of *Xanthosoma* are recognized as distinctively West Indian, and were cultivated by the Caribs when the Spaniards arrived; but, curiously enough, the taro is the only one which has retained a thoroughly native name. The *Xanthosomas* are known, respectively, as "yautia blanca," "yautia amarilla," and "yautia palma," while the taro is called "yautia malanga." *Colocasia esculenta*. Taro. Yauti malanga. Bleeding heart.

Family Araceae; the "taro" of Polynesia. Elsewhere about the Caribbean Sea the same plant has a most confusing variety of native names—"coco" in Jamaica; "eddo" in Barbados; "tannia" in Trinidad; "taya" in the French Islands; "oto" on the Isthmus of Panama, and "tisquisquis" Nicaragua. European travelers and residents are commonly not aware of the differences between these closely similar plants, and generally apply these names indiscriminately to both *Colocasia* and *Xanthosoma*, and some botanists have even failed to appreciate the differences.

The species of *Colocasia* can be distinguished from those of *Xanthosoma* by the petate leaves.

Mr. W. M. Armstrong, of Honolulu, states that he found the Porto Rican taro, or yautia, invariably inferior to the Hawaiian, the introduction of which he considers would be an important service for the agricultural population of Porto Rico. Stock should be secured from Hilo through the experiment-station authorities.

Mr. Armstrong also states that the Hawaiian taro has been found superior to that of Fiji and Samoa by Mr. Alexander, who has investigated the subject. Its wholesome and delicate quality recommend it to resident Americans, and many who have returned to California now import taro for household use.

Recently the Chinese have taken to raising another variety of taro, or taro-like plant, in California, particularly at Bakersfield. This is said to be propagated from tuberous lateral shoots, not like the taro in which the leafy cut-off ends are planted. Chinese taro is also imported to California from Canton and Hongkong. This is by some thought to be somewhat inferior to the Hawaiian, but the difference is not great.

Our readers will notice that the quotations are from a book put out in 1903; and probably considerable progress has been made in disseminating this vegetable, especially in California. If any of our readers can give us any additional information we should be glad to get it.

You will notice the statement that all of these plants are closely related to *Colocasia*; and when foliage plants were my hobby some years ago the varieties of *Colocasia*, especially the variegated ones, were an endless source of pleasure to me. But I did not succeed in making them grow, especially outdoors, as I am now succeeding with the dasheen.

Temperance

"CREATING AN APPETITE."

I want you to take a look at the picture of that boy on page 564 of our issue for August 1. May be you think our boys are not very often taught to drink. If so, look at the following, which I clip from the *American Advance*:

SCHOOL-CHILDREN DRUNK!

Yes, in our land of light and protection for the home!

Read the details in this bit of item from the daily press. It was printed at the bottom of an out-of-the-way column:

81 PUPILS GET DRUNK; PASSAIC SCHOOL REPORT SHOCKS OFFICIALS.

PASSAIC, N. J., July 13.—Mayor George N. Seger, of Passaic, received the annual report of Truant Officer Herman Weber yesterday. Casually he ran his eye down the list of absentees, the list of sick, until he came to a line near the bottom of the page. Then he leaped from his chair and rang the bell violently.

"Send for Mr. Weber at once to explain this," he fairly gasped. "I never heard of such a thing!"

The line of the report that had excited the mayor reads as follows: "Total number of school-children intoxicated during the year, 81."

Mr. Weber, when he appeared, explained that all these children had come to school, at one time or another, drowsy and inattentive, some of them boisterous and quarrelsome, and each case investigated had established the fact that they were under the influence of liquor.

The mayor has issued orders that in the future each case of intoxication among school-children shall be made the subject of a special report and a careful investigation. Among other facts to be noted are the nationality and social standing of the parents, and, if possible, whether the child was given the intoxicant at home.

Of course, we do not know how many pupils there were in that school; but during the year there were 81 that *got drunk*. Without question these children were taught to drink just that the greedy liquor-dealers might get their nickels. Notwithstanding such reports as this, the liquor power has got its hellish grasp so firmly on the affairs of our government that all the good people in all the whole wide world, up to the present time, have been totally unable to break its clutches on our administration.

GOD'S KINGDOM COMING: THE WAY IN WHICH WOMEN ARE VOTING IN ILLINOIS TO BANISH AND KEEP OUT THE SALOON.

We copy the following from the *Union Signal* because it shows in detail how the women went to work, and what they accomplished in one Illinois city:

ILLINOIS WOMEN VOTE ON THE SALOON PROPOSITION. ETTA ROOT EDWARDS.

Vice-president Illinois W. C. T. U.

The first test in Illinois of women's sentiment regarding saloons was made in Benton, July 22. Benton, a city of about 5000 people, is the county-seat of Franklin County. It has had no saloons for five years. This spring, under the commission form of government, a license ordinance was introduced.

The vote stood three for and three against. The mayor referred the matter to the people. So the ballot read, "Shall the ordinance for licensing dram-shops be passed?"

The Women's Christian Temperance Union assumed the responsibility of getting the women to the polls. Mrs. Mary Hart, wife of former County Judge Hart, was made chairman of the central committee. She chose one woman from each ward to act with her in polling the city. The local president, Mrs. Hudgins, then called for volunteers to make a house-to-house canvass, and fifty-six women responded. Each ward was divided into sections, and two women were assigned to each section. A day was decided upon for a whirlwind canvass, and practically every home in the city was visited that day. The canvassers took with them sample ballots from which they showed the women how to vote; some good literature, which they left in the home, and a notebook in which was recorded the name and address of each voter, how she would vote, and when to call for her. These facts were tabulated, and the names arranged alphabetically on separate sheets, ready for use on election day.

The day came. The committee was at the polls half an hour before the time for opening. The first woman who voted was Mrs. Margaret Martin, seventy-seven years old, and for fifty years a resident of Benton. Ten automobiles had been gratuitously placed at the disposal of the committee.

The chivalry of the splendid men of Benton can not be excelled. Ministers, lawyers, business men, city and county officials, clerks and judges, vied with each other in acts of courtesy and kindness.

What was the result? Four hundred and twenty-two women voted. Four hundred and eight of them voted against the saloon. The total vote was 836, and the dry majority was 526.

Judge Hart said, "I have been here for twenty-five years, and I have never seen things so quiet and orderly on election day."

Benton's sweeping victory has sent a thrill of confidence into the hearts of good people throughout this entire section.

There you have it, friends. If you are working and praying to have your town, county, or State dry, and to keep it dry, are you willing to take the time and trouble, to work as did those devoted women?

TAKING THE BABY TO THE POLLS TO VOTE; AND ALSO TAKING THE BABY WHEN A WOMAN IS CALLED ON TO SIT ON JURY.

We copy the following also, at length, from the *Union Signal*, because it foreshadows so well the "good time coming." Our readers will remember that I mentioned taking the babies to meeting in the Grand Traverse region in Michigan.

WHO WILL TAKE CARE OF THE BABY?

Mrs. Sena Hartzell, National Organizer and Lecturer

Once upon a time the question was asked with bated breath, "Who'll take care of the baby when the mother goes to vote?" That question has been answered and exemplified. If no other plan offers, she takes it to the polls with her. Now the question is, What would the mother of an infant do if she were called upon to serve on a jury? At Mitchell, Oregon, a village sixty miles from a railroad, nestling in a beautiful valley, surrounded by towering peaks, where is located a thriving W. C. T. U., the question was admirably answered.

Mitchell is located in what is known as dry territory. A certain man was suspected of illicit liquor-selling. He was arrested, tried before a jury of men, and found guiltless. Again he was arrested, and tried before a jury of men. After deliberating all night they failed to agree, and were dismissed at six.

A VERDICT IN TEN MINUTES.

The judge, now grown desperate, impaneled a jury of women. This jury heard the same evidence, from the same witnesses, before the same judge, with the same county attorney. They were out less than ten minutes when they brought in a verdict of guilty. Two of these women jurors had with them their babies. One took her baby into the box with her. The other, having three children, left the younger ones in the care of the eldest child, who was a girl, and able to look after the baby while her mother sat upon the jury.

As one woman said, "All she had to do was to sit there and behave herself just as though she was in meeting!" Two of these women jurors were mothers of men who served on the jury that could not find sufficient evidence to convict. I had the honor of being entertained at the home of the forewoman, Mrs. E. M. Campbell, an intelligent, well-rounded woman of seventy years. She said, "I never had an easier job. When we entered the room, I said, 'What do you say: is he guilty or not guilty?' and every woman answered, 'He is guilty.'"

THE MOJAVE DESERT "GONE DRY."

As a further evidence that God's kingdom is coming on earth as it is in heaven, we clip the following from the *Union Signal*:

For the first time in its history, Mojave Desert district, California, has gone dry, and all saloon licenses have been revoked.

After a hard-fought battle Pinellas County, Florida, has again outlawed the saloons.

On July 4 the Iowa daylight saloon bill went into effect. Saloons are closed now from 9 P.M. to 7 A.M.

Owing to a new law in Oregon regulating intrastate liquor shipments the Mount Hood Railroad Company has refused to carry shipments of liquor to Hood River Valley districts.

As a result of the Allison law passed by the recent Texas legislature, and in effect since July 1, dry sections of the State will be protected from shipments of liquor from any point in the State. Violations of this law are punishable with imprisonment.

Under the new South Dakota State law which went into effect July 1, limiting the number of saloons to one for each 600 population, Aberdeen reports that thirty-four saloonkeepers were unable to secure renewals of their licenses.

Under the recent liquor laws of Wisconsin, licenses for the sale of intoxicants on boats can not be granted. In discussing the question Attorney General Owen said: "I believe that a license can be granted only for a building that is stationary, and that a license can no more be granted to a boat on a lake than to a wagon that is movable."—*Union Signal*.

THE LIQUOR BUSINESS GOING OUT OF OUR CIVILIZATION.

We clip the following from the *Union Signal*. Read it, and see what you think of it; then see if the concluding sentence hits you anywhere. May God be praised that prohibition has not only struck our railroads and great manufacturing establishments, but that it has taken root, as indicat-

ed in the above, in the hearts of the newspaper advertising men of America.

A significant feature of the recent annual convention of the Associated Advertising Clubs of America, held in Baltimore, was their failure to patronize to any extent the saloons of the city. While it is not unusual during meetings of big social orders for the saloons to keep open all night, they were during this great convention not at all overworked during their regular hours; and, according to a writer in the *Christian Endeavor World*, so marked was the abstinence of the delegates that they were referred to as the "men white ribboners"—"another indication among the many," remarks that paper, "that the liquor business is going out of our civilization." This state of affairs was quite in keeping with the dignified character of the convention as a whole, the first business session being opened by prayer, and members of the convention filling various pulpits on the opening day, Sunday. The adoption of the word "Truth" as the motto of the association speaks well for the ethical standards of the periodicals represented. If the 2000 delegates live up to this motto it will result in the elimination of all liquor and other objectionable advertising from the pages of their papers. Every day brings news of additions to the list of periodicals whose editors and publishers will not soil their pages with advertisements of things that are injurious to their subscribers. The number would multiply with much greater rapidity if the men and women who read would hold up the hands of such publishers, and refuse to give their patronage to those who still maintain a partnership with the liquor interests in advertising their wares.

"BREATHES THERE A MAN WITH SOUL SO DEAD?" ETC.

I have had considerable to say (and, I hope, by way of encouragement) concerning the boys' corn-growing club. It has been estimated that the boys have not only taught their fathers how to grow far better crops than they ever did before, but I have somewhere seen it stated that the result of these corn-growing contests had brought millions of dollars into the State of Iowa. Now read the following which I clip from the *Cleveland Plain Dealer*:

Gov. Cox related one incident to the farmers at the recent meeting at Chardon. One chap, who had entered the contest last winter, wrote to Secretary Sandles saying he would be compelled to drop out and lose his chance, because his father had refused to allow him the use of an acre of ground or the time to prepare the land and cultivate the crop. Gov. Cox expressed astonishment that even one farmer in Ohio should be so short-sighted and pennyurious.

What was it we used to have in our readers?

Breathes there a man with soul so dead
Who never to himself hath said—

suppose we end it by saying, "My boys are not only of more importance than any crop on my farm, but of more value than the farm itself or any thing else in this world;" and yet here is one farmer in Ohio who would not give his boy an acre of ground and time enough to try his hand in growing a crop of corn under the instruction of an expert, even when it is free of charge and paid for by the State of Ohio.

Gleanings in Bee Culture

Editorial

SUGAR TO BE ON THE FREE LIST IN THREE YEARS.

JUST as we go to press, the Senate has passed the tariff bill under which there will be a reduction of 50 per cent in the duty on sugar, with the further provision that it will be placed on the free list in three years. The bill is yet to go to a conference between the two Houses, but it is not expected that any great change will be made. As we said before, we do not believe that free sugar is going to make cheaper honey. Honey has a flavor peculiar to itself; is easily digested, and belongs to a class by itself. It will, therefore, command its own price, just as it has always done, in the face of the fact that glucose syrups are sold from one-half to one-third the price of good extracted honey.

HONEY A CONCENTRATED FOOD.

THE following item from the *Farm Journal* appears to contain considerable truth:

POINTS ON HONEY AS FOOD.

Honey is one of the driest of human foods as it usually has less than 20 per cent of water. Beefsteak, of the most expensive kind, contains 65 per cent, and then there is some bone to be reckoned with. Some of our most expensive fruits and vegetables are nearly all water, 95 per cent, and some even more. This is a point that beekeepers can harp on a good deal. Anybody can easily see that between a pound of steak and a pound of honey at the same money, the advantage lies with the honey. Moreover, honey will keep indefinitely, whereas beefsteak deteriorates in a few hours. Actually, honey improves with age. Add to this the fact that honey is one of the very few predigested foods.—*The Farm Journal*.

Honey is a concentrated food. It is a predigested sweet, and, unlike cane sugars, it is easily assimilated. We have been informed that the British army furnish their soldiers with a considerable amount of cane sugar, because it has been ascertained that sugar in the right quantities is a builder of flesh and muscle. If that is true of sugar it certainly must be true of honey.

HONEY-CROP CONDITIONS; THE SEVERE DROUTH, AND ITS POSSIBLE EFFECT ON CLOVER FOR NEXT YEAR.

As the season goes on it is increasingly apparent that there was a big crop of clover honey in the north-middle Atlantic

States and in south-central Ontario. There has been, probably, a larger crop of clover honey produced this year than for many years back. The crop in the West, if we exclude California, has been about normal; but the severe drouth that has prevailed in some of the eastern States, and latterly through the central-middle States east of the Mississippi, has had a tendency to check the growth for next year. Some report that clover has been all killed out—so much so that they fear no amount of rain from now on will start the plants going. This is particularly so in New York where the season has been a failure and drouth most severe.

If the drouth has been general, it will have a tendency, of course, to stiffen prices on the 1913 product, as there will be some beekeepers who, rather than sell at low prices, will hold for another year. Of course comb honey will have to be sold this year; but as there is only a comparatively small amount of it, there will be no trouble in disposing of it at good prices.

Later.—The drouth has been broken in Kansas, Oklahoma, and Missouri. Refreshing rains have come in the East to some extent. Clover has a wonderful recuperative power, and it is surprising what a few rains will do.

A VISIT FROM A KENTUCKY BEEKEEPER.

GLEANINGS has recently been favored by a visit from Mr. Wallace K. Rheese, of Winchester, Ky. Mr. Rheese is the son of John R. Rheese, who invented the LaRheese bee-escape, which was sold quite extensively for a few years.

Mr. Rheese is a young man full of enthusiasm, who intends to make beekeeping his profession. He sold over \$1100 worth of honey this year from 55 colonies, spring count, and increased to 100 colonies, rearing his own queens from choice stock. In this connection we wish to refer to a statement that has been made, that the extensive producers of honey are nearly all men well along in years, the young men (the sons of these producers) going into other business. If this were true, it would look as though beekeeping were not very inviting

to the younger men. However, we have direct proof that such is not the case, in a good many instances at least, for we are personally acquainted with a good many young men who are going to be the extensive producers a few years hence—young men who are following in their fathers' footsteps.

The glare and glamour of the city draw many of the boys, and some of the best boys too, from the farms, fruit-ranches, poultry-farms, apiaries, etc.; but the introduction of modern improvements and labor-saving devices is going to correct in a short time this abnormal condition. Beekeepers as a class are just as progressive as farmers or fruit-growers, if not more so; and, if we are not mistaken, we believe the proportion of young men who are choosing beekeeping as an occupation or profession is larger than it ever was before.

**"DOT MAKES NO NEFFER MIND;" THE HARD-
LUCK BEEKEEPERS AND FARMERS.**

THE world is full of careless, happy-go-lucky people. There are some, it has been well said, who worry themselves into their graves over little things, and others who go to the poorhouse because they never worry about any thing. As illustrative of the latter class of people, Inspector Morris tells a good story; for at one time in his life he worked in a big shop where there were laborers, mechanics, pattern-makers, and artisans of all kinds. It seems there was an odd "character" in that shop by the name of Hans Drescher. Well, Hans went one day to Bill Huggins, the pattern-maker. "Say, Bill, vill you lent me your trawing-knife? I vant to do a leetle vork mit 'im."

It was contrary to Bill's practice to lend his tools; but seeing it was Hans he turned the tool over to him with the remark, "Be careful, Hans, and do not spoil that nice tool."

"All ride, Bill. I takes goot care mit 'im."

A few hours afterward, Hans came back. "Bill, I made a nick out of dot knife; but dot makes no neffer mind."

The world is full of "dot makes no neffer mind" people. They borrow your tools for which you have paid good money. Likely as not they don't bring them back; or if they do, they return them practically worthless. But the tool-borrowers are not the only offenders. There is a class of "dot makes no neffer mind" who never get anywhere, and wonder why. They are their own worst enemies. Among them are some beekeepers.

They allow their bees to get to robbing,

but "dot makes no neffer mind," because "The other bees get the honey." There are some who leave their old combs exposed out in the open, making it possible to scatter bee disease if they come from an infected hive; but that "makes no neffer mind." They know nothing about bee disease, and care less. Others leave their nice sections on the hive too long. They become daubed with bee-glue, but "dot makes no neffer mind," because the honey is all there, forgetting that they have lost several cents a pound on what perhaps would have been otherwise fancy honey. There are others who never go down into their brood-nest in the spring to replace a failing queen or to strengthen a weak colony, but "dot makes no neffer mind," because the other colonies will get all the honey just the same. There are still others who do not look into the hive in the fall to see if they are in proper condition and have sufficient stores to go into winter quarters; but "dot makes no neffer mind."

Foul-brood inspectors often come across farmer beekeepers of the "neffer mind" class. Their colonies are in all kinds of hives from a nail-keg to a modern dovetailed hive; but in the latter, more than likely, the frames have never been removed, and the combs are built crosswise. Their farm wagons are left out in the open; barn doors are off their hinges; barnyard is reeking with liquid manure; cows stand up to their knees in it. Their fences are tumbled down, and the chickens roost all over the place. They don't seem to see that every day they are losing dollars and dollars. No wonder they have hard luck.

SOME NEW BULLETINS ON BEES.

DURING the last few months there have been some new bulletins on bees. Bulletin No. 49, from the Department of Agriculture, Albany, N. Y., is one of the best and most elaborate that has ever been printed. In addition it is beautifully illustrated with numerous fine engravings. It is written by no less an authority than W. D. Wright, one of the foul-brood inspectors of New York, and one of the best beekeepers in that State. The instructions are safe and orthodox so far as we have been able to see from a cursory examination. Particular attention is paid to the subject of bee diseases. This is followed by copies of the laws relating to bee disease and the spraying of fruit-trees. A large number of beautiful half-tone engravings appear, winding up with splendid illustrations of pickled brood and European foul brood. These are followed by a list of valuable articles that have been

read at the various conventions of the State associations.

EUROPEAN FOUL BROOD AND HOW PURE ITALIANS HASTEN ITS ELIMINATION.

One paper by the author, Mr. Wright, on the subject of Italian bees as a factor in the extermination of European foul brood, is particularly noteworthy. We quote:

When we consider that there is no other race or variety of bees that is so nearly exempt or immune to the ravages of this disease as the pure Italian, and that large or small apiaries of this race often pass through an epidemic of European foul brood of several years' duration almost unscathed, and furnish their owners a good profit at the same time; while, contrariwise, all black and hybrid bees in the vicinity suffer heavy losses, and frequently total annihilation, we begin to realize somewhat the important position held by these bees. There are numerous remedies and treatments recommended for the relief and cure of this malady; but where is there one that will compare with Italianization as a preventive measure before the colony has been exposed, or after treatment, to prevent reinfection?

I consider this item, Italianization, of more importance than any other one, and, perhaps, than all others combined, in the fight against this arch enemy of beekeepers.

In view of the foregoing facts, it is a pity we have no legislation making Italianization of all bees, where necessary for protection, compulsory. However, I presume such a law would be considered unconstitutional.

This statement, coming from an expert on European foul brood, is in harmony with the statement made by several other authorities. A word to the wise will be sufficient.

This bulletin can probably be obtained by New York beekeepers by applying to the Department of Agriculture, Albany, N. Y. Every York Stater should have it. It would probably cost residents of other States 10 or 25 cents, and it would be well worth the latter figure.

Bulletin No. 9, Beekeeping in Tennessee, from the State Board of Entomology, by G. M. Bentley, is another bulletin as large or larger, so far as the amount of matter is concerned. Numerous illustrations, most of them original, show the different stages in the various manipulations in the handling of bees. It is, in fact, a very complete treatise on the subject of handling bee diseases.

It gives a list of honey sources in that State, the present and future possibilities within the State, and then it takes up the subject of apiary inspection, and the report of the Apicultural Inspector, Dr. J. F. Ward. The closing pages are devoted to the relation of beekeeping to horticulture, by Dr. Ward. This bulletin can doubtless be obtained by Tennessee beekeepers by applying to the Tennessee State Board of Entomology, Knoxville, Tenn.

Bulletin No. 11 is devoted to the subject of beekeeping in Iowa, by Mr. Frank C.

Pellett, foul-brood Inspector of that State. This, though not nearly as large as the two other bulletins mentioned, is very complete, in that a beginner by following its instructions could make a nice start in the business. The subject of bee diseases, with a copy of the law, is given on the last page or two. A copy of this bulletin can doubtless be obtained by applying to the Iowa State College of Agriculture, located at Ames, Iowa.

In this connection it is proper to state that this college is one of the very best in the United States. It has a splendid equipment of new buildings; and we have been assured that its president is desirous of having beekeeping taught in the institution. Mr. Pellett is doing much for the cause of beekeeping in his State. While he is handicapped by a lack of funds to carry on properly the work of inspection, yet there is every reason to believe that the time will soon come when Iowa will take its rank with other States that recognize the seriousness of foul brood.

OUR QUEEN-MATING YARD AT THE BASSWOOD GROVE; BABY NUCLEI VS. THOSE USING FULL-SIZED LANGSTROTH FRAMES.

THE cover design for this issue shows a portion of our basswood grove that was set out by A. I. Root over forty years ago, or just about the time his enthusiasm for bees was at its height. He had secured a crop of basswood honey from his 50 colonies that set him wild. Observing that a single basswood tree would yield more nectar per square foot of ground than any other tree or plant north of the Ohio River, he conceived the idea of buying a piece of land and setting it out to basswoods. He purchased twelve acres, and during the next year he set out some 4000 basswoods. Many of them were not more than a foot high, while others were perhaps two or three feet. Well does the writer remember helping to set out those trees. A big Dutchman dug the holes, while we sprinkled in bonedust. We gave the young trees the right kind of plant-food at the very start. The trees grew, and along with them some side shoots. Neighbor H. told A. I. R. to let those shoots grow, as they would furnish more blossoms; but that was a mistake, because they ultimately killed the old tree, and left a lot of small trees all from one root, as will be seen in the picture on the cover. The ground was never thoroughly underdrained, and the trees have never, except in one or two cases, yielded a large crop of honey. One of these cases was during the year 1912.

Young basswood trees, in order to do well, should be grown in connection with

other forest trees; that is to say, the trees should be shaded by larger ones until they get their growth.

Another thing we observed was that nearly every year the outside row of trees would be in bloom while the inner ones showed no blossoms. This would indicate that perhaps the sunlight does not get in to the inner trees as it should. But since draining-ditches have been put in, and the underbrush cut out, basswood honey has been much more in evidence than it was formerly.

Another glance at the cover picture shows long rows of baby hives under the trees. These are our twin mating nuclei, some 200 in all, or 400 separate nuclei. In addition, further down the long rows there are some full-sized Langstroth nuclei in eight-frame hives, two to a hive. This brings the total number up to 450 nuclei for the mating queens at this one yard. In the background, not shown, are some 60 colonies for cell-building and honey-production, an artesian well, two small buildings for a workshop and the storage of supplies.

This whole layout, under the charge of Mr. Mel Pritchard and his son, is devoted entirely to the rearing of queen-bees. When he has a favorable honey year he will produce surplus honey as he did last year and this. In an average year the honey is converted into bees, which in turn are devoted to cell-building and the filling of orders for pound packages and nuclei. This yard will turn out this season about 3000 queens, and, besides that, 5000 lbs. of extracted honey in addition to about 2000 lbs. left in the hives for winter. This year the flow was so strong that even the baby hives were jammed with honey—so much so that the queens were “honey-bound,” and some combs had to be removed, substituting the empty ones.

We have used the twin nuclei at these yards for a number of years. At the beginning of the season we dip up about a dipperful of bees, say a quarter of a pound, and put it into one of the compartments of a twin hive. Another dipperful is put in the other side, making the twin completely peopled except the queen. After all the hives are filled cells or virgins are given, and at the proper age the young mother-to-be takes her flight. As soon as she begins to lay, she is taken out and another cell or virgin is put in her place. When there is a great surplus of virgins we sometimes “prestage,” as already explained in these columns—that is to say, there will be one queen caged while the other is loose waiting to take her flight. As soon as she begins laying, the caged queen is released because she is already introduced. This plan of caging enables us to increase the output

during the mating time in one hive, and at the same time makes it possible to take care of the surplus of virgins. At the close of the season, any bees that are left in the nuclei are dumped into one large box and made up into colonies. While these aggregations of bees do not make as good a colony as the regular, they are worth saving.

The covers of the baby hives are painted red, white, and blue, in order that the queens may more readily locate their entrances on returning from their wedding-flights. To assist further, the entrances point in different directions. For example, the first baby hive may have entrances pointing east and west; the next one north and south, and so on, because the entrances of each hive are in opposite directions. Well, the combined effect of red, white, and blue hives in straight rows, the green grass beneath, and the foliage of the basswoods, with every now and then glimpses of the blue sky above, makes a general combination that is inviting. Visitors always remark about it. It can be plainly seen from the street cars as they whizz by. We take visitors to this yard because the bees are very easy to handle, requiring neither smoke nor veil. It is well known that a little bunch of bees is less inclined to be “obstreperous” than a large-sized nucleus or yet a strong and powerful colony. Mr. Pritchard, however, uses smoke as a matter of convenience to facilitate his work. He never finds it necessary to use a veil. If the entrances are contracted, there will be little or no trouble from robbing. But it is an advantage to have the big colonies away from the little ones, and you will find them in the extreme background out of sight.

The question may arise, “Which is the better—the twin baby hives or the full-sized Langstroth?” That depends. For general purposes the large hives are better. They take a little more time, however, to manipulate, and from four to five times as many bees. Moreover, these big nuclei are very handy for filling orders for one-pound packages and nuclei for shipment.

Our Mr. Wardell sees no particular advantage in baby hives. They cost considerable to start in the spring, because they must be *started every season*. In early spring 200 nuclei will take 100 to 150 lbs. of bees. These, taken from strong colonies in the spring, so sap their strength that they are not worth much for honey. Two or three pounds of bees taken out of a colony makes it necessary to remove the brood and replace it in other hives that may not be able to take care of it to advantage, for the simple reason that they already have all the brood they can take care of.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

"EXTRACTED honey will be much more wholesome to use than sugar." That's what T. B. Terry says in *The Practical Farmer* when speaking of sweetening oatmeal. Terry has been slow to recognize the value of honey, but is not likely to take any backward step. That pronouncement of his will do a lot of good.

A KANSAS reader says he has more trouble introducing ripe queen-cells than queens, and asks the best way to introduce them. The trouble comes almost surely from introducing cells too soon after removing the queen, before the bees are yet conscious of needing either queen or cell. Wait a day after removing the queen, then introduce any way you like. You may make a safe thing of introduction at the time the queen is removed by using a West cell-protector. Or you can introduce it in a cage the same as a queen. This last has the advantage that the bees are slow about tearing down the cell, so you can see whether the queen has hatched or not. When not protected, the bees are likely to remove all traces of the cell, so you can't tell whether the queen hatched or the bees destroyed cell and all.

"If a colony, slightly affected with foul brood, should cast a swarm, would the swarm, if placed on new frames and new hive, be liable to the disease if not exposed afterward?"—D. W. H. I don't know. My guess would be that it would be safe 99 times in 100 with European foul brood, and not quite so safe with American foul brood. [The base of the cure for foul brood, both European and American, is putting the bees in a clean hive. A swarm makes use of this principle in that it leaves behind it its combs, and usually enters clean new quarters. Again, it is generally understood that swarms do not carry foul brood. Putting these two facts together it would seem that Dr. Miller's statement could be made a good deal stronger. While there would not be much danger of European foul brood following, there would be no danger of the American type showing up.—ED.]

I DON'T believe alfalfa-growers can be persuaded to delay cutting till after alfalfa is in bloom, and I don't believe they ought. Much alfalfa is now grown here, and we're well up in alfalfa lore. The old rule was to cut when one-tenth was in bloom. Now the more intelligent rule is to cut as soon as the new growth starts at the base of the stalk. If cut later the new growth will be up in the way of the sickle, and the next crop

injured, and at this time not many blossoms are out. But alfalfa is no good for bees here anyhow. [Has it been proven beyond doubt that there is any advantage in cutting alfalfa before it comes into bloom? Many ranchmen apparently believe that the early cutting furnishes better hay. Perhaps so; but does it furnish a greater quantity of nutriment to stock? In other words, will an early-cut hay that has not reached its full growth and development yield more beef and pork than alfalfa cut after it comes into bloom? If we mistake not, there is a disagreement among authorities, with the odds rather in favor of the early cutting. But the pendulum has been swinging the other way, toward a later cutting. We hope so, as this will mean more honey, and probably more hay. See what Mr. Higgins says in the Heads of Grain department, in this issue.—ED.]

A BIG jump has been made in parcel post by the postmaster-general by making the rate within 150 miles a cent a pound plus 4 cents, with an increase in weight-limit from 11 to 20 pounds. Then the c. o. d. feature is a good thing. But the insurance is not what it ought to be if we are to ship honey by parcel post, and I don't see why honey shouldn't be thus shipped in this country as well as across the ocean. May be not yet, but after a while. Well, you can insure a package; and if it is lost you can recover value. But if you ship a case of honey and insure it, and it's smashed in transit, and the dauby remains are delivered, not a cent of loss can be recovered, because the thing was not a total loss. [At present we do not think it would be advisable to ship either comb or extracted honey by parcel post. See experience of Mr. Moody elsewhere. So far the results have shown that any fragile article is likely to receive pretty rough treatment in the parcel-post mail-bags. Unfortunately, almost every thing is being sent in this way, whether fragile or not. A heavy package will be bumped against a light and fragile one, with the result that the latter will be smashed into smithereens, if, indeed, it ever reaches the consignee. We see no reason why comb and extracted honey should not share a similar fate, damaging every thing else in the mail-bag. Parcel post has been a great boon to the people of the country. If we give Uncle Sam, or, rather, the Postmaster-General, a little more time he will probably be able to eliminate some of these breakages.—ED.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

Mr. Chadwick makes a good point when he says, "The time is coming in this land of ours when more men must be producers, and fewer live on the work of those who do produce."

* * *

We hear occasionally of a bee-sting that struck a nerve or a vein, and consequently was very painful. Perhaps! But I have come to think that there is a great difference in the virulence of the poison of different bees. I sometimes receive a sting that seems almost inert, and the poison as harmless as so much water; and, again, I receive a sting causing unusual pain. The sting of a young bee seems much less severe than that from older ones.

* * *

I believe it was Louis Scholl who, some time ago, said that it is better for the specialist to have his yards of bees some distance apart. Then if there was a failure in one section he might get a crop in another. The present season in this section has seemed to verify the wisdom of such advice. Where some of our yards were located, and where we usually get fair crops, we shall not secure enough honey to winter the bees, while another yard, twelve or fifteen miles distant, where the drouth was not so severe, will give a good yield.

* * *

"There is that scattereth, and yet increaseth even more; and there is that withholdeth more than is meet, but it tendeth only to want." This is as true to-day as when first written some three thousand years ago. Especially is it true of beekeepers. How many have we seen that made a careful investment in bees, improved hives, sections, smoker, and beekeeping literature, that have reaped ten—yes, thirty, sixty, and even a hundred per cent on their investment, while others who thought they could not afford good hives, a smoker, nor a bee journal, have found it tended only to want and poverty!

* * *

It is nearly seventy years since I stood beside the gentle "schoolmarm" to learn my letters, and I repeated them one after another as she pointed them out with her wonderful pencil or more wonderful pen-knife, little thinking that some day I would be teaching the alphabet of beekeeping. And as I hold up a comb and point out the eggs and young and sealed larvæ, the work-

er and drone brood, and show the difference between healthy and sick or dead brood, and hear the exclamations of surprise from those who have kept bees for many years, I am astonished at their ignorance. An inspector must teach as well as inspect if he would have his work endure.

* * *

Mr. Jay W. Gee has an enlightening article on p. 375, June 1, on the shipping of fragile articles, and he speaks from experience in actually handling them. The fact to the care with which they are packed is to the care with which they are packed was a new idea, and yet it seems reasonable it should be so. That a few sections placed in a case of corrugated paper, and fitted nicely into a basket with handle, should go safely, is not at all surprising. I am of the opinion that, if all our shipping cases of honey had a handle they would go far more safely than at present. Mr. C. B. Palmer, on p. 450, July 1, calls attention to the use of a candy-pail for shipping honey. He attributes his success to the fact that the pail is not set down flat with a slam, but strikes first on one edge and goes down gently; but I believe the handle has more to do with it than he thinks. I fear if the handle were removed the pail would not prove of so great value as a shipping case for honey.

* * *

How far will bees go in search of nectar? and how many bees can be kept in one place without overstocking? are questions that have never been answered positively, and I believe never will be, for it all depends on circumstances. Mr. Harbison, of Southern California, told me many years ago that he found his bees working on flowers fifteen miles from home, although not very freely. The past spring it seemed doubtful if bees would go more than half a mile from their hives. The weather was so cool and cloudy about here that, where many colonies were kept in one location, they had to be fed to prevent starvation. A few colonies in a place during dandelion bloom would fill their hives, and some of them would prepare to swarm, while colonies in large yards could gather but little, as they could not go far from their hives, and the nectar was soon exhausted. On the other hand, during clover bloom there seems to be but little difference between large and small yards, as the weather is then mild, and bees can fly much further.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

On a recent trip to the San Bernardino Mountains I made a special effort to gain some knowledge of bee life in that region, and hope to submit an article a little later on my observations, illustrated with some pictures made by my own camera.

* * *

I have just made my first experiment in feeding thin syrup to prevent robbing while working with the bees, and I am not altogether satisfied with the result. It did not check robbing altogether, and I had one colony nearly cleaned out while my work was in progress. Later I tried wheeling the hives into the honey-house while at work with them, and then replacing them on the old stand. This plan proved very satisfactory.

* * *

The theory that alfalfa, in those parts of the State in range of the ocean winds, does not produce honey, is thoroughly exploded so far as my mind is concerned, owing to personal observation. A few weeks ago I was passing within half a mile of a field that was blooming nicely. I left my rig and walked over. I not only found bees, but great quantities of them, with every indication that they were getting honey at a very fair rate.

* * *

The most distressing feature of the season to me is the fact that my hives are now several pounds lighter in stores than they were two months ago, which means that colonies with a fair supply of stores then will have to be fed liberally by spring, and the weaker ones watched carefully to get them through. The stronger and better-supplied colonies will be able to pull through without much help. We can not afford to lose even the weaker ones, for it very often happens that we get some of our best honey-flows following these extremely dry seasons. Those are the seasons when the weak colonies soon come to the front and make big returns.

* * *

The skunks are again making inroads on my supply of bees that is already too low. I have never seen them quite so bad as at the present time, and the bees are so cross from their continual annoyance that the mere brushing past the hives brings out a stream of them to attack the intruder. The crosser colonies seem to fare the worst, due, very likely, to the fact that they are more easily brought out for an attack than

those of a more mild temper, and of course that is just what the skunks are after—the more that come out, the quicker they can finish their meal. I am again using strychnine to destroy them, but the process is slow, as there seems to be no end to the number that are harbored in the rocks near by. I have never been able to figure out why they are so much worse at this time of the year than at any other time.

* * *

The fight that has been waged against our old friend in the bee business, whom we know familiarly as Prof. Cook, now State Horticultural Commissioner, culminated last week in a hearing of the various charges before Gov. Johnson; and, if we are to believe the press reports, the charges fell flat for want of proof to sustain them. One thing that impressed me more than any other in the defense of Prof. Cook was that the records of his office were used in his defense, which seems to me to be about the best defense a man could have if his office has been properly conducted, as must have been the case here or they never would have been used for defense. It will be remembered that the fight on Cook *started* when he discharged the chief deputy quarantine inspector, and was *augmented* by the discharge of another of the official family some time later. The continual howl by certain fruit-men and fruit-papers brought about the hearing before our Governor. I have had very little sympathy for it all, because it was sprung before Cook had had sufficient time to prove himself efficient or otherwise. One fruit-journal wrote me taking exceptions to my defense of Cook when the fight was first begun; but now that he has been exonerated, and even those who led the case against him have admitted that they made a poor showing, my first opinion of the matter is confirmed. One thing is quite sure—the fruit-men will from now on know that A. J. Cook is the State Horticultural Commissioner and is square in the saddle. It seems to me that it is “up to” the fruit-men to get in and help now, and drop the policy of obstruction, for it must be remembered that some of the best fruit-men of the State were defending Mr. Cook. Governor Johnson said in effect regarding the dismissal of men from the commissioner's office, that it was no care of his who Cook discharged—that it was the efficiency of the work of the commission that most concerned him.

Beekkeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

LOCATING THE HIVES IN AN APIARY.

Hundreds of pictures of apiaries have been presented in the bee-journals and other publications from time to time. The writer has always found a certain amount of interest in studying them, there being quite a difference in the make-up of apiaries of various owners. In other respects they resemble each other very much—for example, in the placing of the hives. Has it not occurred to the readers that the great majority of apiaries are arranged with the hives placed either in rows or sometimes in squares, but with every hive a certain distance from its next neighbor? Are not the most of the hives placed so that every hive looks very much like the next hive or any other hive in the entire apiary? In many instances this "monotony" is broken only by the unfortunate(?) presence of such obstacles as shrubbery, trees, buildings, etc.

Such arrangements have their objections. The worst of these is in the matter of queens entering the wrong hives and being destroyed by the strange colony entered. This is the common cause of many colonies becoming queenless, especially after honey harvest. The apiarist can not account for this, as there seems to be no special reason why so many of his colonies should be found with missing queens. The trouble may, however, be attributed to the fact that many queens are superseded after the honey harvest; and the queens going out to mate return to the wrong hive because there is too great a similarity between the different hives adjoining their own. This is also true during the swarming season—in fact, at all times of the year when queens are likely to come out to mate.

Another disadvantage is that such an arrangement requires a lot of room unless the hives are placed close together. The closer together, the worse the trouble, however. The better way is to place the hives in pairs. Even groups of threes are better. A queen coming out of any hive in such a group will

take notice of the way her own hive is located in relation to the next hives, either to one side or the other, as the case may be; and when they return they will be less likely to go into the wrong hive.

To remedy the faults of an apiary arranged either in straight rows, exact squares, or on the hexagonal system, the colonies should be so shifted about until the entire yard is arranged in groups of two or three hives. Long rows of hives can easily be treated by simply moving every other two hives closer together, when space permits of this being done. If they are too close together already, the best step to take is to remove one hive from between every two hives in the row. That will leave the remaining hives in pairs, while the removed hives can be arranged in new rows.

The drawing shows an out-apiary fenced off, the wires stretched from tree to tree as indicated. There is room to place ten groups of five hives under a like number of trees or clumps of trees in the enclosure. The hives are located so that the greater number of them face southeast. By close observation it will be found that three hives facing this way are placed in a row "in front" of the trees. Another hive, facing northeast, is placed slightly in the rear to the right, while a fifth hive, facing southwest, is plac-

ed in a like position just opposite. Enough space is left between the backs of the hives and the trees to enable free passage and sufficient room for working over them.

[Half-tone engravings illustrating this plan will appear in the next issue.—Ed.]

Conversations with Doolittle

At Borodino, New York.

HONEY—HOW MADE.

"How do bees make honey? Is the nectar in the flowers honey? We know that the bees gather the nectar, but is that all there is to it? An old beekeeper told me that bees make honey. I denied it by telling him that bees gather honey."

Honey is produced by bees from nectar, and nectar is only a secretion of certain floral organs of plants. Bees will not gather any thing else if they can get nectar in paying quantities (unless their sense is perverted by robbing) as nectar is their natural food. This shows how they appreciate flavor. I know bees will gather such substances as fruit juice, sap from maple trees, or other plant wounds, aphid discharges, sugar syrup, etc., but such as these can hardly come under the term real honey. Possibly, if there is such a thing as honeydew this might be entitled to the name of honey after being stored and capped over by the bees; but, if I am correct, this, as well as such substances as those named above, lack in flavor, and could hardly be classed as good floral honey. Little honey would be eaten if it were not for its flavor, for the same amount of nutriment could be more cheaply secured by buying sugar and making it into a syrup of the consistency of honey. Flavor carries an important item in the economy of nature; and so important do we consider it that we add it to our food as we desire. Does not the flavor of ice-cream give it the delightful taste which causes us to be so eager for it? The flavor stimulates the appetite, and very likely aids in digestion. Of what worth would we consider the multitude of good things which we now enjoy when eating if all of them were deprived of flavor? Honey gets its value and character largely from its flavor, and its flavor is mainly derived from principles contained in the nectar. Each kind takes its distinctive flavor from flowers, each kind of flower having its distinctive source. I have been told that the honey takes its flavor from the secretions of the bees; but if this were true, what becomes of the wide difference in flavor of honey from the nectar of different trees and plants? Wonderful indeed would be the power of the bees if they could give such difference as is seen between the mild basswood honey and the rank buckwheat.

Honey is a rich, nutritious food. Its nutriment comes from the sugar it contains. Properly speaking bees do not gather *honey* and store it in their combs, but they gather the *nectar* of flowers, and through manipu-

lation and evaporation change it to honey. Honey is the prepared food for the colony, stored away for their future use. They not only manipulate the nectar, doubtless adding some of their secretions to it, but they generate more or less of the heat necessary for the changing of the nectar into honey. Bees possess a wonderful faculty for generating heat. When needed, they can bring the temperature inside the cluster from 80 to 95 degrees F. when it is down to zero in the open air. Of course, nothing of this kind occurs at times of nectar-gathering; but when nearly or quite a freezing temperature occurs during a night after a good flow of nectar from fruit-bloom, no lowering of the temperature inside will be noticed unless this freezing temperature is long continued. When the nectar is first gathered by the bees it usually contains an excess of moisture that has to be removed before it can become honey. The heat within the hive and cluster causes the moisture to evaporate, and the warm air of the hive to absorb it. To drive this moisture-laden air out of the hive the bees rapidly vibrate their wings. New air rushes in to supply its place. This goes through the same course of being warmed, circulated, moisture-laden, and finally driven out at the entrance. Many times have I seen water running in front on the alighting-board on a cool morning after a good flow of nectar.

Then all nectar is manipulated by the bees taking it in its raw state into the honey-sac and forcing it out into the mouth parts, drawing it back into the sac again; then forcing it out again, and so on until it becomes honey of sufficient density for capping over. By this operation, besides the evaporation of moisture, sufficient secretions of the bees are added and mixed with the nectar to make it honey when properly thickened. These secretions are probably needed to hinder fermentation and decomposition of the nectar. They also give a change in flavor, so that the honey does not have the same flavor as the perfume from the flowers from which it is gathered, nor the smell of the raw nectar when first brought in. Take buckwheat for instance. The aroma from a field when in full bloom, as it is wafted to our nostrils by a gentle breeze, is very inviting and lovely. But at nightfall, after a day of heavy gathering in a large apiary, no carrion could be more offensive to one who knows not the source from which it came. But after the bees have changed this raw nectar into thoroughly ripened honey this bad smell is all gone.

ECONOMY IN RAISING QUEENS

Saving all the Brood from the Old Queen while the New One is being Reared

BY WILLIAM LOSSING

If there is a honey-flow in the locality, any beekeeper can secure a "bouncer" by complying with a few simple rules for raising queens, taking into consideration quality of queens and the least expenditure for time. My plan is applicable to home yards as well as to out-yards, and I have demonstrated its practicability beyond a doubt.

First divide a two-story hive, using an extra bottom board for the purpose. Select all the sealed brood, adhering bees and queen, place them in the upper story, leaving the eggs and larvæ in the lower story. There will now be perhaps four frames of brood in each story. Many workers will return to the old entrance, while enough will remain with the old queen to keep the brood from chilling, especially with the assistance of the heat from the lower story. As fast as the brood hatches, the queen will quickly deposit eggs in the vacant cells, and by so doing nearly the full benefit of the old queen is retained. At the same time the eggs and larvæ are being cared for by the bees in the lower story which are also building queen-cells.

We will suppose that we are at an out-yard fifteen miles from home, where honey is coming in, drones flying, and preparations are being made for swarming. We will go through the whole yard as above outlined, taking three days, say, for one hundred colonies. All yearling queens are in the upper stories, and nearly all the fresh brood and eggs are in the lower story. (Date each day's work.) In eight or ten days we remove all queen-cells but one, that being the best one in each hive. Perhaps ten per cent of the colonies are poor cell-builders, and in that case we destroy all of them and insert a good cell from another colony. The work is now done for the next fifteen days.

On returning, use very little smoke at the entrance of both upper and lower stories; remove the upper story; raise the quilt from the lower story; and if a young queen is laying the bees will be seen in a whirling motion directly over where she happens to be at that particular time. This sign is visible for only an instant, and practiced eyes will locate the queen immediately.

About five per cent of the young queens are lost in mating. When this occurs, on

lifting the quilt the bees often commence to hum very loudly, indicating that their queen is lost. (This sign fails occasionally.) If the bees are queenless, draw off two combs of fresh brood and bees (not the queen) from the upper story, changing combs with the lower story. After going through the whole yard we will say that there are six queens lost. In each of the six colonies two combs of fresh brood and eggs have been supplied.

Return to this yard in ten days, start at number one, and go straight through the whole yard, exchanging two combs of the ripest brood that each old queen has for two empty combs from the lower story minus the bees from each. After reducing the old queen again, ten days after this the colony with the young queen below will be strong enough for supers. When this time comes, do not delay, but put a super on and put the upper story that contains the old queen on top of it.

Keep drawing the ripest brood from the colony containing the old queen on top from time to time till within twenty days of the honey-flow. Now pinch the old queen's head; cage the young queen, and unite the bees. In due time release the young queen. All the bees and eggs the old queen produced have been saved, and there is a prolific young queen in the hive that will not swarm on the slightest provocation as an old queen will, nor fail during a long honey-flow.

Phoenix, Ariz.

[This plan requires a locality where there is quite a long period of warm weather before the main honey-flow.—ED.]

ENGLISH SPARROWS AS ENEMIES OF BEES

BY A. J. WRIGHT.

In the list of enemies to bees are toads, snakes, dragonflies, bee-birds, skunks, moths, worms, and domestic fowls. An experience that I had two years ago convinced me that the list is clearly incomplete. At the time mentioned I had a large queen order on hand, and began early in the season to raise queens in order to fill it. I had good success in getting a nice lot of virgins hatched and in the nucleus boxes; but when they took their mating flight at least 75 per cent failed to return. Another lot of virgins met the same fate. I succeeded in filling orders, but failed to raise enough queens to requeen my own apiary, which I much de-

sired. I lost many dollars' worth of queens, and worker-bees by thousands.

Accidentally I discovered the cause. I was working in the apiary when my attention was called to a flock of English sparrows perched in single file on the ridge board of the barn and cornhouse, and in line with the flight of the bees. Some of the sparrows were in the air all of the time, and were busy snatching up the bees; and when the bees would come in loaded and drop down on the roof of the buildings the sparrows would hop down and gather them in. I did not count the birds, but should judge that there were from fifty to seventy-five in the flock. I earnestly urge every beekeeper to make war on these pests. They certainly nearly ruined my apiary, and are, without doubt, the worst enemy of the bees and beekeeper. There is no mistake about the matter.

I know of but very little that can be said in favor, and very much to be said against the bird. I might possibly overlook the fact that it is a destroyer of cherries, grapes, pears, peaches, and other fruits, and buds of trees, vines, garden seeds, the tender shoots of young peas and lettuce, together with wheat and other grains (a flock of fifty sparrows requires the equivalent of a quart of wheat daily, making the annual loss caused by these birds throughout the country very great), and the further fact that the English sparrow drives out our native birds, killing their young and destroying their nests, also defiling buildings, ornamental trees, shrubs, etc., with their excrement and bulky nests. I say I might possibly overlook the foregoing; but when these little tyrants attack queens and worker bees, and endanger the safety of an entire apiary, I think it time to call a halt.

To show the nature of this bird I will relate the following incident, of which I was an eye witness. Three years ago the barn swallows built about thirty mud nests under the eaves of the barn above referred to. They were not molested by the sparrows until the swallows had young nearly large enough to fly, when the sparrows attacked them in a body, pulling the helpless young from the nests and dropping them on the ground and roof of the chicken house below to die of cold and hunger. The sparrows took possession of the nests and kept out the swallows. The same tragedy was enacted the following season, and the swallows deserted the location. The same thing occurred with a nest of bluebirds in an old tree.

I recommend that beekeepers send for Government Bulletin entitled "English

Sparrows a Pest" (No. 493), which will be sent free on application to your Congressman or to the Department of Agriculture, Washington, D. C., telling how to destroy these pests; but please be careful not to destroy the little chipping sparrow, which somewhat resembles the English sparrow, but is smaller, and differs considerably in its markings, for it is a friend to the gardener and beekeeper. A pair of the "chippies" kept a patch of twenty-five cabbages in my garden entirely free from cabbage-worms during an entire season, and destroyed many moths in my apiary. Unlike the English sparrows, the little chipping sparrows never do any damage.

Bradford, N. Y.

A DENTIST'S METHOD OF PRODUCING HONEY

Beekeeping Compared with Poultry Raising

BY P. E. WAUGH, D. D. S.

I am a professional man keeping a few hives of bees for pleasure and profit; and like many others, the amount of pleasure I derive is, in a large measure, in proportion to how well my bees do, season conditions considered. To be honest, my fondness for honey was the real incentive for beginning; and when a neighbor told me he got 20 lbs. per colony from box hives I decided to get one. However, at about this time I borrowed a copy of the A B C of Bee Culture, and found out more about beekeeping in an hour than my neighbor knew all together. One hundred sections per colony is common, and sixty my lowest average.

With a little experience I found I should need one or two colonies to experiment with—one to supply honey for my own family, and a few to furnish that tidy little sum of money each year that adds just that zest to the business that holds the interest year after year.

I have my own scheme for swarm prevention that works in most cases, and I certainly get the honey. Having two shallow bodies to each colony I reverse them as soon as the top one is full of brood and honey, and put the supers on top. The queen now occupies the upper body; and as soon as it is pretty full I reverse again. The super work is now started, for I use baits in the super; and if in looking over the hives I find queen-cells I take away the super (bees and all) and give to the nearest very strong colony not showing queen-cells, putting an empty super in its place containing baits and empty sections. Then I reverse and take away a super again if necessary. I give as many as three of these supers to some strong hives; and how the bees do work! I

have a space below frames open full width at both ends.

I introduce queens of different races; raise young queens; find by personal observation how old a queen is before she mates, and how soon after she begins to lay; keep old queens after the bees decide to supersede her and watch both queens laying on the same comb, etc.

The work is all pleasant, and not to be compared to keeping chickens. The supers are prepared indoors during leisure hours, for recreation. If a big cloud comes up, I don't have to telephone my wife to gather the live stock to keep it from standing under a weed and getting chilled or drowned. What a pleasant sight it is to see the bees come pouring into the hive when the sun becomes overcast and the first cool breeze of a spring storm stirs the leaves! Chickens are a nuisance in town, any way you look at it. I had them several years, and made them pay too. But they are dirty things, and require endless care and looking after.

No, sir! Give me bees. I believe I can demonstrate that I can produce enough honey from *one hive* for the average family's yearly use, using shallow extracting-frames in super with full sheets of foundation and a good colony of Italian bees.

Tola, Kan.

ANOTHER DENTIST WHO FINDS BEEKEEPING ON A SMALL SCALE A HEALTHY EXERCISE

BY DR. R. M'CULLOUGH

Of all the professions, that of the dentist is the most exhausting in that it has, in addition to all the other strenuous conditions peculiar to professions, the element of close confinement added, and that, too, for long hours. This feature is so fatal that reliable statistics show that the average life of the dentist is only about forty-five years, which indicates that the man who allows his work to master him—that is, who attends strictly to business, as we are so often admonished to do—is destined to early retirement. The logical conclusion, then, is that the dentist who wishes to survive must have some outdoor attraction; and I will most positively say that "bees are it."

When I say that, I mean that beekeeping is far beyond any other avocation I know of, and I think I have tried them all. I have been advised, times without number, to take long walks, morning, noon, or night; but without an incentive one is simply not going to do it. Now bees offer that incentive.

Some fine spring morning you see your

bees coming in with great loads of bright-yellow pollen. Where are they getting it? Before you realize it, off you go to find out; and after a good tramp you may find them working merrily on the pussy willows. Then by the time you have lost interest in the source of the yellow pollen, another color catches your eye, and you are off again to ferret out the new source of supply.

All the time this is going on, with what pleasure you note your bee family growing full and strong for the coming harvest, and all without the everlasting worry of feeding, watering, cleaning coops, etc., attendant on poultry-raising for instance.

By the time you have located the source of most of the pollen your attention is attracted by the heavy manner in which your bees are dropping down to the entrance, and the general appearance of hustle in evidence. Away you go, and, may be, after two or three morning tramps you discover the locust trees in bloom, and the air filled with their fragrance and the hum of bees; and you go on to your office with a smile on your face that lasts all day.

So it goes from spring to frost, always something new, giving your pets this little attention or that, until you arrive at the close of the year, and realize that you forgot all about taking that vacation which you have usually been compelled to take; and when you begin to analyze your condition you are compelled to admit that you never felt better in your life.

But suppose you did not forget about your vacation; well, go ahead and take it. See that the bees are not cramped for room in the mean time, and they will be there when you come back, probably all the better off for your absence, and you will not have bothered your neighbors to feed and water them while you were gone either.

I have been writing as one professional man talking to another, and I think I can not do better than to go on in that strain. All that I have been saying can probably be summed up in a few words by intimating that I have been getting the outdoor exercise of which I was so much in need, without the consciousness that I was just doing something for health's sake.

Poultry may give you something to interest you out in the back yard; but the back yard is the limit of your interest; and accompanied with it is the constant responsibility so that, when the first enthusiasm wears off, you begin to feel more tied down than ever, which in reality you are. The same might be said to a greater or less degree of almost every other avocation with the exception of bees.

With them your interest is extended to

the whole territory surrounding you; and through your curiosity to ascertain the source of pollen or nectar, or the cause of this or that activity, you find trees in blossom that you never dreamed had a blossom, or that what once you considered a noxious weed possesses flowers which, for intricacy of form, relegates the American beauty to the commonplace. What great variety of size and form of bloom, simple and compound, making it hard or easy for the bee to arrive at the coveted sweet within! and with what untiring perseverance the little fellow labors to acquire the precious load! And then the home of the bee itself! what everlasting interest and wonder are enclosed in the four walls of their little house! But why say more? All these things are better appreciated when seen than when read about; and the pleasure is all in finding out for one's self rather than told.

I do not know that I can do better than to tell something of how I myself became interested in bees. As I intimated earlier, I had gone pretty well the rounds in avocations—so much so that it got to be something of a speculation in the community as to what Dr. Mc. was going to raise next. One day when I went to our public library the librarian handed me a journal with the remark that it would likely interest me. It proved to be Christmas number of *GLEANNINGS* for 1908, and interest me it did. I have it yet, though much the worse for wear. That winter was spent reading every thing I could get my hands on relating to bees; and the following spring found me with a hive of bees on my back porch, having at that time no other place to put them, much against the wishes of Mrs. Mc., who protested that the children would be stung to death. I will admit that I had some concern in that regard myself; but we were happily surprised to find that the bees confined their attention to their own business and bothered no one, regardless of the fact that the children played on and about their hive, and rather roughly at times at that.

As a further inducement to the good wife to allow me to enter upon this new venture I proposed that the product of the hive should be hers. This arrangement has proven satisfactory in more ways than one—satisfactory to her, as it nets her from five to eight dollars a year pin money, and satisfactory to me in that any inquiry of me as to the purchase of honey is referred to her, relieving me of the mercenary side of the proposition.

This statement causes me to suggest to any who might think of keeping bees as an avocation to keep only a few bees, say not more than three colonies, so that your

pleasure in them will not be converted into a burden, and also so that the idea of profit in dollars and cents from them does not overshadow the profit from healthful exercise, and freedom from anxiety in regard to them. You keep bees for your health; let the fellow who keeps them for a livelihood do the worrying as to the mercenary side of them. Stick to your own business for your living, and to your bees for recreation.

Pittsburg, Pa.

HONEY AND BEES AT THE HAMILTON COUNTY FAIR

BY HENRY REDDERT

The agricultural fair just ended was a great success in all its details. The efforts of the fair committee were duly appreciated by the great crowds of visitors during the four days of attendance.

There were two entries of bees and their products, and one entry of beekeepers' supplies by Mr. Charles H. Weber. Mr. J. G. Creighton, of Harrison, Ohio, secured first prize on the best display of comb and extracted honey; first prize on wax and comb honey, and live bees in observatory hives. Mr. Lenert, of Elwood Place, took the first prize on extracted and second on comb honey and beeswax. Mr. Creighton's honey was all in crystal-white jars of various forms and sizes, from a gallon down to a pint. Mr. Lenert's honey was in green jars—a practice all exhibitors of extracted honey should avoid, as it gives a different hue to the honey. The honey he received first prize on was in a small crystal-white pint jar. Had he used white jars for the entire display it would have shown up very much better.

The exhibitor should use various forms of jars, and set them in such a way as to make a harmonious picture to draw the attention of the visitors. Mr. Creighton's wax was not as light-colored as Mr. Lenert's. It was chocolate-colored and put up in twenty and five pound pieces, and so formed as to resemble a decorated chocolate cake. Had he not marked it, nine out of ten people would have taken it for such. I was puzzled myself until Mr. Creighton explained. I presume the bulk and shape secured him the first prize on wax.

We have quite a number of large beekeepers in our county who have the time to make a good display if they would only make up their minds to do so. To my mind it is a great advertisement to beemen who sell honey in large quantities, retail and wholesale. Then, again, it helps to enlight-

en the public as to the good uses of honey. I saw no department where people were so deeply interested as in our small honey-gatherers. The time I was present (and he told me it was the same the entire four days), Mr. Creighton was constantly busy explaining the various operations of the hive. He showed them the queens depositing eggs the same as if in their own yards. This aroused considerable interest.

Cincinnati, Ohio.

FRANK RAUCHFUSS

BY WESLEY FOSTER

The Germans are the greatest beekeepers in the world. The largest beekeepers' associations are in Germany. Furthermore, many of our American beekeepers are descended from German stock. For instance, my grandmother Sehnee never learned to read English; but her German Bible was her comfort. My father was half German, and so my instinct for beekeeping and the taste for honey was early manifested.

The four best apiaries in Colorado, in point of care and tastefulness of arrangement are owned by three Germans and one Swede, and the Swede learned his beekeeping from a German neighbor. Mr. Frank Rauchfuss is one of the Germans. There is no beekeeper in the West, or in Colorado in particular, but that knows Frank Rauchfuss personally or by reputation. Coming to this country when but a lad, he clerked and kept books, and managed departments in mercantile establishments in New York, Louisville, and Denver. While in these lines of work he became familiar with American business conditions. For several years he managed the bee-supply department for the L. A. Watkins Mds. Company, of Denver, and while there his career began as chief organizer of the Colorado Honey-producers' Association.

With his brother Herman the Rauchfuss foundation-fastener and section-press was brought out, and practically every specialist in Colorado has one. A simpler and more efficient machine has not been made.

In 1899 the Colorado Honey-producers' Association was organized, and Mr. Rauchfuss was made manager. A room was rented beside the L. A. Watkins Mds. Company's warehouse, and there the beemen hauled their honey and received their supplies on Saturday afternoons when Mr. Rauchfuss was off duty at his regular employment. The business soon grew so that it was necessary to keep the store open every day. Mr. Rauchfuss resigned his position with The L. A. Watkins Co., and

has been manager of the Honey-producers' Association ever since. He is a quiet, unassuming man, of definite ideas. Any one acquainted with him knows of his strong characteristics in this line. One of the book-keepers of the Association once told me that when a beekeeper who had been doing faulty grading came into the store she left the office because she could not stand it to hear Mr. Rauchfuss "go" for him.

Mr. Rauchfuss has hobbies the same as all of us. He has a spotless little place out in Aurora, a suburb of Denver, where he pursues gardening, poultry-raising, bee-keeping, and the raising of goats. At the last account he had five goats, I think. If you never drank goat milk you don't know that the Jersey cow has a superior in the way of a cream-producer. Mr. Rauchfuss told of an amusing experience he had at the interstate fair in Denver. The judges tested the milk that he exhibited, and found it so much richer in butter fat than any other that they charged him with having mixed cream with it, which charge he denied with all the earnestness possible. Later, when he told them that it was goat milk, he had the laugh on them.

Mr. Rauchfuss works in his garden a good deal, and I have been told that a weed could not be found inside the fence. It is probably true, for I never saw any there. With the few lots for garden and fruit, the poultry, the bees, and the goats, the income is no doubt augmented several hundred dollars yearly. A better example of intensive gardening could hardly be found than the one I am describing. Mrs. Rauchfuss took the first prize at the interstate fair in Denver not long ago, and her honey-cooking recipes exhibited on the demonstration train delighted every one, which is only a proof of her excellent cooking. Mr. and Mrs. Rauchfuss have a little son, Walter, who can talk German, but thinks it more polite to talk English because the other boys do.

After having told you these rambling things about our friend, you will be interested in visiting him any day at the office of the Colorado Honey-producers' Association in Denver. You will find that he can tell many interesting things about western beemen and western conditions in general.

Boulder, Colo.

Slabs of Candy for Winter Stores

Last winter, in my own apiary there was no loss. I wintered out of doors in common dovetailed hives. I kept slabs of candy on top of frames, chaff cushion on that. My bees were stronger April 1 than they were Nov. 1, making honey on the first bloom at present.

Morrisville, Mo., May 1.

H. CLAY DAY

Apiary of J. L. Strong, Clarinda, Iowa. The apiary house and south part of the yard are not shown. There are four rows of hives, twenty-five in a row. The small hives shown are twin mating hives.

THE BROOD-SURFACE IN DIFFERENT-SIZED HIVES

How Different Conditions have a Bearing on the Problem

BY ARTHUR C. MILLER

Brock uses ten-frame hives. Oppenheim-er uses twelves, and Old Man Philetus uses eights; and each one is cocksure that he has the right size, and that the other two are wrong. Perhaps each is right. What do you think?

"Location," did you say? "Location be hanged! No, you needn't get huffy, but just listen and cool off.

Brock uses a standard ten-frame body in which the frames, after a little swelling and propolizing, fit so snugly that the outer surfaces of the outer combs are so close to the hive sides that they rarely have any brood put in them, and hence not much on the other surface. So he really has but little more than eight combs available for brood.

Oppenheimer's twelve combs fit about as do Brock's ten, so he loses nearly two, leaving him with but about ten for brood.

Old Man Philetus' hives are standard eights, with ample room for the frames which are kept away from the hive sides so that the outer surfaces of the outer combs are occupied with brood.

Didn't realize how nearly alike the different brood-nests were, eh? Well, they are nearer than that; and, what is more, Old

Man Philetus actually has more brood in his hives than either of the others.

We will do some measuring and counting, not because you like to fiddle with figures, but because they are good for your mental digestion.

A standard L. frame with inch-thick top-bar has an internal area of 134 square inches. Figuring 25 cells to the square inch, and doubling it for the two surfaces, such an area would have 6700 worker-cells; by count it is 6800. Those are the figures provided the combs are built on foundation and fill the frames. But how many combs approach that condition? Let us go to the different yards and see.

O. M. P.'s combs fill the frames solid from top-bar to bottom-bar, and from end to end, and all worker comb—that is, all but the lower half of one comb in each hive, and that is drone comb, and all the drone brood is there. Wise Old Man Philetus! His combs are beautifully filled with brood, even regular sheets of it, and only a narrow line of honey and pollen next the top-bar.

Deducting the half-comb of drone and the total area used for pollen and honey in the eight combs, we find that there are about 45,000 cells of worker brood. (Not nearly enough for a good queen and best results, as O. M. P. has learned, and he is changing to larger hives.)

Brock has good combs built on foundation in wired frames but the combs do not touch the bottom-bar, and are rounded off

Mr. Luke, of Jefferson Co., Ind., and a part of his bees.

on the lower edges or have a fringe of drone-cells and more of the same in the lower corners. By measure we find that an area equal to a frame and a half is thus wasted. In other words, he gives to drone comb about double the surface given by O. M. P., and loses the area of half a comb by unoccupied space. The amount of honey and pollen is much the same as in O. M. P.'s, except that the two outer combs are all or nearly all honey and pollen.

By measure and estimate we find Brock's ten combs when in use have available for worker brood the equivalent of but seven perfect combs of the O. M. P. capacity, or 47,600 cells.

Brock doesn't like the showing, but has to admit its truth. To make him feel better we will take him with us to Oppenheimer's.

O.'s "twelve-frames" look immense beside O. M. P.'s "eights," yet there does not seem to be much more hustle, except of drones. We open up some hives, and here is what we find. (Really it is a shame to expose O., but after all it is best for everybody concerned.) Some of O.'s combs are built from starters, some from full sheets, some wired and some not. The two outer combs contain only honey and pollen. The other combs contain many drone-cells, sometimes a strip along the lower edge two to three inches wide; also spots of them here and there over the surfaces. The brood

in these combs is not in solid sheets, as in Brock's or O. M. P.'s, except in the combs where wired frames of foundation chanced to have been used. Pollen and honey are found in patches here and there among the brood; and where the foundation has stretched, wide strips along the top-bars are filled with honey. By measure and estimate we find that O. has the equivalent of but seven combs of the O. M. P. type.

To be sure, his queens have more room to lay; but it is in drone-cells, and hence a loss to him. And Oppenheimer is mad, and insists that his combs are as good as the average run of combs. He is right, there; but the "average" is lower than what a hen lays an egg on daily.

By a little figuring, we shall find the available worker-cells in the three typical classes of combs to be as follows:

O. M. P.'s "Best," 6460.

Brock's "Good," 5950.

Oppenheimer's "Average," 4760.

But more brood is produced in the same worker-cell area of "Best" and "Good" combs than in the "Average," so the latter are even poorer than the figures indicate.

That is a long way around to reach the point; but the longest way around is the nearest way home, or is so reported by persons not really strictly sober.

One of the boys will say that his queens keep only an eight-frame hive properly full of brood, while his neighbor says it takes

A portion of the apiary of Mr. Chas. McCauly, Jefferson Co., Ind.

trees. In ordinary years, everywhere one looks there is a profusion of white bloom. Basswood, locusts, poplars, blackberry, raspberry, yellow and white sweet clovers, asters, and white clover seem to vie with each other in the abundance of their bloom. In most parts of the county the sweet clover, basswood, locust, and white clover are the chief sources of nectar.

This is about the only locality in the State where nearly every one keeps bees. However, there are few professional bee-

keepers. The chief beekeeper, Mr. Chas. McCauly, died the past winter, and with him has passed the chief of the professional beemen. It was Mr. McCauly who first brought in yellow sweet clover, and he was the first to demonstrate that Jefferson County has a honey-flow so dependable that one may make honey-production his only source of income. There are hundreds of beekeepers who keep from one to twenty colonies. Not many keep more than fifty, but a few keep a hundred or so.

Most of the county is very broken. The twelve combs to accommodate his queens. Possibly it is the queens; but it *may* be the combs. Better find out before you waste ink and paper and use up valuable space in the magazine, as I am doing. Lest you should run out of food for thought, consider the following: It costs less to get "Best" combs than it does those of the "Good" grade; and when you take into account trouble and labor, combs which have to be cut out and replaced, excess of drone combs, uneven comb, etc., you will find that the "Average" grade is the most costly of the three.

These are cold hard facts. Use the cold part to relieve your aching head.

Providence, R. I.

BEEKEEPING IN JEFFERSON CO., IND.

Sweet Clover Preventing the Land from Washing

BY B. F. KINDIG

I am always glad when my work calls me to Jefferson County, Indiana. The hills and valleys covered with a mantle of honey-producing plants always fill me with admiration. This is the home of the locust

Picturesque drive shaded by locust trees.

FIG. 1.—Combs of colony with Isle-of-Wight bee disease.

forests have been pretty well cut over. Where the land is not cultivated, the locusts have taken possession of considerable areas. The land that has been cultivated or pastured is mostly covered with sweet clover. And sweet clover has been the farmer's salvation here as in many other places. It stops the washing, or prevents it. It puts the necessary humus and nitrogen into the leached hillsides, and rejuvenates them. With the clearing of the forests the natural fertility began to decline, and the hillsides washed until there was almost no vegetation to cover their rocky sides. Then sweet clover came and put new life into them. Blue grass began to take root, and white clover followed; and now those slopes to which sweet clover first came are covered with a beautiful carpet of blue grass through which peep millions of white-clover blossoms. In addition, sweet clover, that "noxious weed" which has been fought with scythe and by legislation, has gained a well-deserved victory and now furnishes tons of nectar for Jefferson County beekeepers.

Although the land is of limestone formation, it is common to find some of the flat hilltops sour. But that is to be expected unless the region be rather arid, for the tendency toward sour soil increases with the increase in total annual rainfall. Usually only the flat hilltops and ridges and the fertile bottom lands are cultivated. The sweet clover on the hillsides is usually cut once, and then allowed to grow up and

bloom. This gives an excellent flow of later honey.

Very few colonies of bees have to be fed in the fall, for ordinarily the aster flow is sufficient to insure an abundance of winter stores.

Jefferson County has a smaller number of cases of foul brood per hundred colonies than any other county in the State that I have investigated. Both European and American are here, but are only rarely found. Some years ago foul brood was a common trouble; but after their sad experience the beemen are on the alert, and use

vigorous measures wherever a case develops. One item that probably contributes largely to the scarcity of foul brood is the large number of bee-hunters and the resulting small number of bee-trees. In some counties of this State, everywhere one goes the cry is, "Give us a law that will allow us to

FIG. 2.—Condition of bottom-board under Isle-of-Wight disease colony.

enter upon a man's premises and cut the bee-trees so that we may destroy the sources of infection." Here the unwritten law is that, wherever a man finds a bee-tree, it is his to cut and rob. I feel sure that this custom is in a large part responsible for this small per cent of foul brood. But this is the locality par excellence for sac or pickled brood. I have found it in hundreds of hives, but it rarely proves very serious.

On May 23 many colonies were literally living from hand to mouth. Spraying when the fruit-bloom was open weakened many yards, and a number of colonies were reported to have been killed. There was very little locust bloom this year. A very dry period, followed by cold rainy days, prevented any considerable work on the white clover. Beekeepers in general were feeling very pessimistic in regard to this year's honey crop; but at this date, June 7, a bumper honey crop is in the making.

Indianapolis, Ind.

THE ISLE-OF-WIGHT BEE DISEASE

BY JOSEPH TINSELY

The beekeepers of these islands are considerably disturbed by the prevalence of the Isle-of-Wight disease; and although it is some time since it appeared in England, yet it shows no signs of abating. Formerly it was known more as a summer or early spring complaint; but in our own county we have had a rude shock in the way of winter mortality.

The symptoms in the summer are well known. I was called to a case last July. A beekeeper had a dozen excellent colonies. The bees were storing honey rapidly. When I went over, each colony had fully 60 lbs. in the honey-chambers; then, as if by magic, the Isle-of-Wight disease gripped them. The sight was most peculiar. Thousands of bees were crawling all around the hives, unable to unite their wings. Small pieces of grass and weeds around the apiary were seized upon by the insects to raise themselves higher, where they clustered in knots. The bees were swollen; and if one was pressed with the feet the excreta would spurt out as if the whole body of the bee contained nothing else. Sulphur and several advertised cures were tried, but all in vain, and the bees dwindled away rapidly.

Considerable conflict of opinion is being noticed in England at the present time as to the cures. Some have achieved success with certain remedies, while the same remedies in the hands of others have met with no success. The investigations made by the

FIG. 3.—Bottom-board covered with the excreta of the diseased bees.

Board of Agriculture have also done very little toward the eradication of the disease; and in their official report they state definitely that there is no cure, and advise burning. Until last year we were not seriously visited in this county with the pest, although it was in adjacent counties. The losses in some places are enormous. I know of more than 500 colonies being lost in one county alone. Even the experimental apiary connected with the British Beekeepers' Association at Swanley was attacked by the pest.

The winter state of the disease is all the more alarming. The bees go into winter quarters in apparently good condition; but when one takes his early spring peep to see how things are going he finds a great many

FIG. 4.—The bee on the left is diseased. Notice the distended abdomen and the unnatural appearance of the wings. The bee on the right is healthy.

A 2½-year-old beekeeper.

dead bees. I was called by a beekeeper in February who had lost half of his colonies with the Isle-of-Wight disease. I took photos of the bees, which I enclose. In illustration No. 1 are three combs taken from the dead hive, showing the exact condition of the stock. On the right hand is a fine comb of honey, weighing approximately 6 lbs. There were three like this. In the center will be noticed a small patch of brood, showing that the queen did her work right up to the last; and it is a peculiar feature of the disease that the queen is the last to die. I found her very easily, and her body was quite fresh, giving one the impression that she had not been dead more than a day. The comb on the left consists of empty cells where many of the bees clustered only to die. The bees were badly swollen, and all over the interior of the hive, and on the combs, was noticeable the peculiar faeces emitted by the bees.

The second illustration shows the floor-board. Not a live bee left. The sight was appalling, and we walked away from the apiary wondering what would happen next. The beekeeper in question was one of the most up-to-date men we have. Every thing that could be done for the bees had been done. They had clean, dry, sheltered situation, and plenty of good food and winter covering. Foul brood is insignificant in comparison. I have seen 60 lbs. of honey produced from a colony suffering from foul

brood; but I doubt whether we shall see 6 lbs. from one suffering from Isle of Wight. This year up to the time of writing I have seen no less than 10 apiaries devastated as a result of the disease.

One point I have noticed very particularly and that is that I have not seen a colony of Italian bees with this malady. Of course I am only speaking now of what I have seen, but I have great faith in the Italians as disease resisters. On the other hand, we have a number of beekeepers in England whose bees are kept in any thing but a proper manner, and who pay no attention to the improvement of stock. Possibly a lowered vitality in the strains of bees in this country has been responsible for the pest finding a home. This, of course, is my theory only; but as I have studied the disease since its first appearance in this country, and am in communication daily with the best beemen in the British Isles, I hope to state some reliable facts shortly.

Stone, Staffs., Eng.

A "NEW" BEEKEEPER

BY FRANKLIN E. JAMES

After keeping bees for a year I would say that I have had more genuine pleasure and gained more knowledge than I could have believed possible; and, besides, they have more than paid for themselves, as I got a good crop of honey. There are many beekeepers around here; but most of them still use box hives, and have little acquaintance with their little workers. Some of them still sulphur the bees whenever they want to "take" the honey, and no amount of persuasion can make them change their methods. I am sending a photo of my youngest boy; and, although only 2½ years old when the picture was taken, he could handle the frames in a hive nicely. When I asked him to pose for his picture this is what he did, saying, "They won't hurt you."

New Bedford, Mass.

SNOWDROP AS A HONEY-PLANT IN IDAHO

BY F. F. GEORGE

I believe you need an up-to-date picture of a wonderful honey-yielder, snowdrop (buckbush). By looking a little close you will notice almost a mass of white berries. I am quite sure nurserymen once sold it by the above name; but I think I will submit to the name "buckbush."

This plant blooms here in June, before the white clover. I have a bottle of the honey

secured in June, 1910, that is not candied yet. It is very light amber now, but water-white when first extracted. The flavor is very pleasant, and it does not detract from the flavor of white clover. The plant grows everywhere here, from 6 in. to 4 ft. high. Pheasants and cattle eat the berries. The cattle also browse on the tender twigs in summer. It has been reported to me that the same bush bears red berries in northern Missouri. They are white here, and they have a mild, sweet, bitter taste.
Fraser, Ida.

AN OPEN FENCE FOR A WINDBREAK

BY GEORGE SHIBER

After carefully reading all that had appeared in the journals on the subject, I built a windbreak last fall in order to shelter my bees from the winter winds. I decided to have it 7 feet high; and knowing that it would have to withstand hard wind pressure I selected 4 x 4-inch posts imbedded three feet in the ground, with two cross-pieces of 2 x 6-inch stuff.

Then the question was, whether it should be tight or open; and if open, how much so? After considering the matter on both sides I decided to have it open—that is, the boards were 7 feet high, and separated two inches. I concluded that, if it should appear that the tight fence was better, it could be easily changed.

I was agreeably surprised to note the difference in a strong wind, the inside being comparatively calm. The air was just in motion. The entrances to the hives pointed away from the wind also.

Well, I concluded that the colonies ought to winter well. They were abundantly fed last fall; and now I am reminded of something Mr. Byer wrote Jan. 1, p. 10, to the effect that the paramount question in wintering by any method is that of having plenty of stores in the hives. From my experience I would most emphatically say that he need not guess again.

I used planer shavings for packing, placing a hive-bodyful above the frames, and that is all the packing they have. No paper or packing is around the sides of the hives at all.

Of course, up to date, Jan. 20, we have had a very mild winter, and we may have some severe weather yet, but so far every colony has wintered well—I might say perfectly.

I do not think my windbreak will have the disastrous effect mentioned by A. J. Halter, p. 55; for when there is a wind the cool air is in motion inside. The enclosure

Snowdrop, or buckbush—a honey-plant in Idaho.

is sufficient, I think, to keep them in the hives when too windy to fly safely.

The editor is, I think, entitled to credit for bringing up this point strongly. It seems, therefore, to me that a windbreak, of whatever kind it is, should be somewhat open; and yet subsequent experience may prove it to be wrong.

Inside the windbreak the snow is distributed evenly, not drifted at all.

I do not like to have the snow drift around the hives, as it has a tendency to make the inside of them damp. I want perfect dryness to prevail in the hives.

Randolph, N. Y.

THE NEW TEXAS FOUL-BROOD LAW

BY WILMON NEWELL

The new Texas law relative to bee diseases, mention of which has heretofore been made in these columns, went into effect July 1, and is, perhaps one of the most comprehensive laws on the subject that have yet been enacted. Briefly stated, its main provisions are as follows:

Sweet-clover roots. Photograph sent by W. E. Kirk, Amarillo, Texas. The seed was sown six months before the roots were pulled. The center root weighed 4½ pounds. The root at the extreme right grew on sod land.

The law previously in effect is repealed, and the new law specifies that the Entomologist of the State Experiment Station shall be State Entomologist of the State, and have charge of the enforcement of the law. Under the former law the Professor of Entomology in the Agricultural and Mechanical College was State Entomologist. This change was made principally because such work as eradicating foul brood was deemed more appropriate for an Experiment Station than for an educational institution. This change in the law does not, for the present at least, make any change in the incumbent of the office of State Entomologist, as Mr. Wilmon Newell, the State Entomologist, is entomologist of the Station, as well as Professor of Entomology in the College.

Section 3 authorizes the State Entomologist to issue such regulations relative to quarantines, shipment of bees, etc., as may be necessary to a proper enforcement of the law, and any violation of these regulations is defined as a misdemeanor.

The provisions of Section 4 require that all bees, except those shipped in wire cages without combs or honey, when shipped into the State be accompanied by the certificate of the State Entomologist or Chief Foul-brood Inspector of the State from which they are shipped. However, in those cases where a certificate can not be obtained from the proper State official, or where there is no State inspection of apiaries, permission to make the shipment into Texas may be obtained from the Texas State Entomolo-

gist upon the presentation of suitable evidence showing the bees to be healthy. As noted above, these requirements do not apply to the shipment of bees in wire cages without combs or honey. On shipments of these there are no restrictions. The provisions relative to queen-bees are in exact accord with those of the Postoffice Department, i. e., queen-bees must be accompanied by a certificate or by copy of an affidavit showing that the honey used in making the candy contained in the cages has been suitably boiled.

The law authorizes the State Entomologist to make regulations relative to the interstate shipment of used hives, fixtures, etc., and makes it obligatory upon all common carriers to comply with such regulations.

Shipments of diseased bees found in the possession of any common carrier may be confiscated by the Entomologist or his inspectors, and, for purposes of inspecting bees that are in process of shipment, these officials are authorized to enter railway depots, cars, express offices, etc.

The new law is, perhaps, unique in its provisions for the quarantining of counties or other areas within the State of Texas. The State Entomologist may impose either a "protective" quarantine or a "restrictive" quarantine in any county or group of counties. A protective quarantine is defined as one which is to keep diseased bees out of any county or other area which may be either free from the disease or in process of being freed by the work of eradication.

Such quarantines as this have heretofore been in force in Texas. That is, whenever the attempt was made to free a county of foul brood, the movement of bees *into* that county was prohibited except upon their being inspected and found healthy. The restrictive quarantine, on the other hand, provides for prohibiting the shipment of bees out of any county or other area in which disease is rampant. The object of the restrictive quarantine is to prevent the general dissemination of disease from any badly infected locality.

In the enforcement of the new law the State Entomologist is given authority to take testimony under oath, to compel the production of books and papers, and require the attendance of witnesses for examination. The sheriffs and constables are required to assist the State Entomologist in the discharge of these and other duties whenever called upon to do so.

Provision is made for the publication of literature of importance to beekeepers.

Provision is also made for the transfer of bees from box hives to frame hives, upon order of the inspector; and in the failure of such transfer the inspector may transfer the bees and thereafter legally collect from the owner the costs of the transfer. In a similar manner the cost of treating diseased bees may be collected from the owner thereof.

The malicious exposure or distribution of diseased combs, fixtures, or infected honey is made punishable by a fine of from 25 to 200 dollars. The penalty for selling or bartering diseased bees is the same. A similar penalty may be imposed upon any one convicted of trying to prevent inspection of bees, either through threats of physical violence or by intimidation.

The foregoing statement includes the most salient points in the law which are of interest to the general reader. Texas beekeepers will, of course, find it to their interest to have a full and complete copy of the law at hand.

As soon as conditions permit, the State Entomologist of Texas (whose address is College Station, Texas) will issue the new law in booklet form for general distribution to the beekeepers of that State, and to such other parties as may be interested in its provisions. We are advised that these booklets will probably be available for distribution by Sept. 15 or 20.

College Station, Texas.

SMOKERS

A Larger and More Efficient Smoker Needed

BY R. F. HOLTERMANN

To me the bee fraternity often appear like a flock of sheep or a cluster of bees especially black bees that have been smoked too much, and are following those who start a run, not thinking whither they are going. What I mean is, that there is too much of a tendency for the majority to follow others regardless of the wisdom of doing so. In this article I am going to undertake to say something to the beekeepers; and if, incidentally, it hits the supply dealers, it will not be the first blow they have had.

My special complaint in this article is the smoker question. In my estimation there is not a smoker advertised by any supply dealer in this continent which can not be made vastly more efficient, especially for the beekeeper who uses such a device hour after hour, and also for one who has only a few colonies, because, as a rule, a beginner is more timid, and requires a volume of smoke at a moment's notice. Let me say here that I am no advocate of heavy smoking. I object to unnecessary smoking; but, nevertheless, there are times when, owing to weather or possibly to some blunder of our own, the bees become almost unmanageable. And it is then that smoke is needed at once, and lots of it.

It is unnecessary for me to trace the history of smoking bees. I believe some trace it away back when the progeny of bees burned to death in forest fires inherited the fear of fire, etc. To my way of thinking, the bees fear smoke because of their sensitiveness, and because of their highly developed breathing-organs which are irritated and stifled by smoke.

It has been my hope that somebody would invent something practical for the apiary with which to smoke bees that would be less trouble than the regular smoker. But my present purpose is to seek to *improve* the smokers. The compartment for the fire has been enlarged somewhat from time to time, and no doubt there has already been a vast improvement; but when a smoker that is always in use requires loading so often, and thus takes valuable time, I have wondered why the capacity for fuel could not be still greater and thus save more time. I therefore ordered Jumbo smokers with the fire-cups three inches longer than usual. These I have used for several years. Last winter I decided that I wanted even a larger fire-cup as well as a larger bellows, and so ordered a dozen of that kind. The chief rea-

son why I ordered these smokers is because the grate at the bottom of the fire-cup is stamped, legs and all, out of one piece of metal, and there are thus no obstructions to the grate to interfere with the draft.

The sample smoker that I received first had a fire-cup $4\frac{1}{4}$ inches in diameter, and $8\frac{3}{4}$ inches long without the cover; and the bellows was $5\frac{5}{8}$ inches wide by $8\frac{1}{2}$ long, the leather being 4 inches wide at the top. This smoker was so superior in the estimation of those helping me, that whenever I was working with the bees I had to have it plainly understood that this extra-large smoker was *mine*.

Brantford, Ont., Canada.

BEE CULTURE AND ITS POSSIBILITIES

A Glimpse from One Locality in the South

BY A. I. ROOT

I said to our people a few days ago that it was no more than fair that the great wide world should know what is being done and what can be done in a wide section of territory; and to commence with I sent a letter to our good friend Marchant, asking him some questions. Below I give you a list of those questions and his reply.

Friend Marchant:

What I should especially like to know is, how many colonies of bees you had to start with last spring; your yield of honey, say in tons, and about how many colonies you have now. If you have sold bees to any amount, of course that would come in. Then I should like to have a brief statement as to the sources of honey, and, if you have no objections, state the price you receive for it. I suppose you do not produce comb honey—at least not to any extent. We should like to know, also, how many out-apiaries you have, and how many colonies you find it best to keep in each apiary. Do you have an extracting-outfit located at each apiary? or do you carry your extractor around to each apiary? Any other items you may think of interest we should be glad to get. One reason I have asked the above is because I fear our people have been a little backward about letting the world know the possibilities of bee culture.

Your old friend,
A. I. ROOT.

Mr. A. I. Root:—The number of colonies of bees I started with last spring was 530. This includes the hospital lot, which was about 40 colonies that did but little toward gathering any surplus.

My yield of honey was about 30 tons. I now have 700 colonies. I also sold 100 1-lb. packages of bees with queens. These came out of this lot of 530. Of course I have a queen-yard independent of this lot. This honey came from the ti-ti, black gum, and willow, but the surplus came from the black tupelo and the white tupelo. It brought me f. o. b. here $7\frac{1}{4}$ to $7\frac{1}{2}$ cts. During spring, or the main honey-flow, I had only two

yards besides my queen-yard. At present I have five outyards, but will unite them into two or three yards next spring.

I find that from 250 to 350 is best for each apiary, but I have had 1000 in three yards, and they did equally well.

I have an extracting-outfit at each apiary.

This lot of bees would have produced several tons more of honey had it not been for a flood in our river during the main honey-flow, and lasting all through the flow. This caused the bees to become demoralized, especially during swarming, when lots of them were lost in the water. Besides, the apiary could not be kept up to the standard, as one could not take care of the swarms. In fact, you could not tell what hive they came from; and, of course, the parent colony, not being operated to cut out all cells, this caused afterswarms and crippled the apiary a great deal. The yard that was overflowed had 380 colonies.

In some correspondence I had with the company some time ago I wrote them my crop brought \$3100. This was sold to one man alone, and I forgot to mention the rest I had furnished to my regular customers.

A. B. MARCHANT.

Apalachicola, Fla., Aug. 25.

[Perhaps I should say right here that many successful beekeepers have objected to printed reports of their work, because there are always a lot of foolish people who will dump a lot of bees right into their neighborhood, thinking, evidently, that it is locality and not the man that "delivers the goods." I heard this same thing in California. In fact, it has been discussed all around; and our neighbor Rood in Florida objected to reports of what he had done, because several times his locality was overstocked by beekeepers moving into the neighborhood or locality. Therefore please do not think of moving bees where these big reports come from until you have first corresponded with the man making the report. In this way he and you could arrange a location that would not be likely to interfere with his own field. See "Overstocking" in the A B C book.—A. I. R.]

Wintering Nuclei in One Hive

I have several nuclei with queens that I wish to winter if possible in order to save the queens. Would it be all right to divide a ten-frame hive into two or three parts with wire window-screen, giving each nucleus a separate entrance? The hive is a double-walled chaff, in protected location.

Indianapolis, Ind., Aug. 2.

W. E. GREEN.

[The plan proposed might work, but it would be our opinion that it would be better to use thin boards, ~~say~~ 3-16 inch thick, in place of the wire cloth.—Ed.]

Heads of Grain from Different Fields

How we Give Live-bee Stunts Before an Audience

I have an engagement to give a live-bee exhibit at our county fair this fall. This will be my first experience. Is it advisable to feed the bees while they are confined?

Wausau, Wis., Aug. 14.

O. S. LUNDE.

[Generally speaking, we would advise gentle bees for live-bee-demonstration work. However, for our own uses we would not pay any attention to that matter. When our regular men are away we sometimes select the bees at random, not knowing what their temperament is, and we have never had any trouble so far.]

We never have fed bees just before operating. It might and probably would have a quieting effect. To handle bees inside of a wire-cloth cage or in a lecture-room, it is necessary, of course, to use smoke in removing the wire-screen top of the box or nucleus. It is our plan to use a big dishpan. Into this we shake one or more frames of bees just as we do during extracting time. The bees are caught in the pan, when it is given a little shaking—not violently, but gently enough so the bees lose their colony spirit. They are then in condition where they can be scooped up by the handfuls. Right here it is necessary to observe caution. Our plan is to roll the bees into a ball by a manipulation of the pan, then cause the ball to roll on the hand. If this is done carefully, there will be no danger of stings. At other times one might scoop them up provided the movement is very gentle and cautious, *being careful not to pinch or crowd a single bee*. We have given some 200 or 300 bee demonstrations of this kind, and have never been stung once.

The next stunt is to dump a couple of handfuls of bees into a hat. Give the hat a little shake downward, taking the precaution to get every bee off the hat-band; then adjust the hat gently to the head. For this purpose a soft felt hat is better than a stiff one. The next stunt is to lift the hat off the head, and shake all the bees from the hat on to the head.

The next stunt is a little more ticklish. There will be no danger of stings providing the operator is cautious. The fingers of each hand should gently comb the bees out of the hair. The few that may be left after combing will gradually leave of their own accord.

Another stunt that we have indulged in occasionally is to put bees in the mouth and let them fly out one by one. But we would not advise any one to practice this stunt unless he knows himself to be practically immune to bee poison. We have never been stung more than once, and yet we have put bees in the mouth many a time.

In giving these various demonstrations we have stepped out of the cage and walked down through the audience. Sometimes we take along a frame of bees, point out the queen, the drones, and the worker bees. If the operator walks slowly down the aisles he can give every one in the audience a pretty close inspection of a comb of bees and the bees themselves.

We recently spoke before about 800 teachers at the summer school located at Wooster, O. A close examination of this frame of bees seemed to please the individual members of the audience as much as any thing. The very fact that the operator has bees on his head and a frame of bees in one hand seems to inspire confidence in the audience; for if the bees do not sting the operator they certainly will not sting the individuals in the audience.

It is usually our custom to tell bee stories while walking up and down the aisles with bees—tell how bees gather nectar; how many trips they have to make to get a pound of nectar; how they pollinate fruit-blossoms; how they sometimes rob from each other; how the queen bee is "introduced" to her subjects. While these things are commonplace to a

beeman they are exceedingly interesting to one who knows little or nothing about bees.

At the close of our demonstration we give the audience an opportunity, by means of little strips of wood, to have a taste of liquid honey and honey butter (candied honey). We also show samples of comb honey, queen-cages, introducing-cages, and other appliances for working with bees.

If one is "on to his job" he will be able to delight an audience, giving them a novelty such as they have never seen before. To be able to handle bees in the manner described, with bees on the head and shoulders and in the hands is profoundly interesting as well as startling to the average audience. We were never stung on any of these occasions except once, and that was when we borrowed an old stinking hat from a volunteer in the audience. It was the first one proffered, and so we could not well refuse it. When we dumped the bees into that hat, its odor seemed to rouse them into a frenzy. We had promised to put a hat of bees on the head, and so we had to "take the consequences." The bees resented being put into such quarters by giving us a number of stings. We took it all calmly, and no one knew the difference except one old farmer who came up shortly afterward and said, "Say, mister, was there one bee that stung you?"

"What makes you think so?" we answered.

"W-a-l-l, mister, you looked as if there might be one bee stinging you."

The fact was, the good wife pulled out, the next morning, something like thirty stings.

We go on doing these stunts, but have been careful ever since to use only our own hat or one that is reasonably clean.—ED.]

Sending Honey by Parcel Post Not Satisfactory; Two Queens in a Hive

I have tried an experiment with honey by parcel post. Two packages of four one-pint fruit-jars, each jar wrapped once with corrugated paper, stood on more such paper, in a heavy pasteboard packing-box that fitted so that only a few (two or three) crumpled newspapers could be crammed around and between jars and box, and covered with corrugated paper and heavy strawboard, all securely carded, were mailed, one for over 200 miles, the other less than 100. They were plainly marked "Extracted Honey," in large letters. Either package could have been thrown across the room without damage, for no jar would have hit any hard object. Result, two jars were broken in each package, effectually sweetening that lot of mail. I believe that, at least for the present, honey to go safely by parcel post must be in tin containers, with the covers well soldered on, and the whole boxed in one-half-inch wood. My two packages weighed just 11 lbs. each, the limit then.

Some one shut the queen in above the excluder accidentally. That hive grew to four stories before the bees quit flying out, and sent out a big swarm besides. When extracting time came we found only two bodies full of sealed honey, while the lower two had each a queen and the frames were full of eggs and brood.

Florence, Ala., Aug. 18. H. A. MOODY, M. D.

[Packages sent by parcel post must be capable of standing pretty severe handling. So far Uncle Sam has not eliminated the trouble arising from breakage. We do not believe that extracted honey, either in glass or tin, and much less comb honey, should be sent by parcel post, no matter how carefully it is packed. A small sample, say half an ounce or an ounce, when put inside a solid wooden block, will go through all right; but a pound or two is quite liable to be broken. For a further consideration of this question, see Straws in this issue.]

The queen that got above the excluder made it possible for another queen to be raised in the hive. During the honey season there may be one or more queens in a colony, providing they are separated by a perforated zinc; but as the season winds up they will all be killed off but one. Experience has shown that it would be very desirable if we could arrange to have two queens in a hive; for then it would be possible to have big colonies, and large colonies are the ones that gather the honey. If one queen should die suddenly, the other would be immediately available, and this would be quite an advantage.—ED.]

Producing Comb and Extracted Honey, and the Prevention of Swarming

As it is quite possible to control swarming with two nine-frame-story Langstroth depths, since the queen does not occupy half of the upper story with eggs, wouldn't a half-story of five-inch frames, nine frame size, on top of a nine-frame Langstroth-depth brood-chamber, and one or two comb-honey supers, answer the same purpose of swarm control? One shallow extracting-super and one comb-honey super would give a depth of about ten inches instead of the Langstroth extracting-size of $9\frac{1}{2}$ inches in depth. As I am a comb-honey producer I should greatly prefer the shallow extracting-super to the Langstroth extracting-super if it has the same power to control swarming, as it would leave me room for more comb-honey supers.

Chichester, Que., Aug. 1.

ALF. POTVIN.

[The shallow-depth super, if the combs were fully drawn, might do nearly as well. Indeed, it might be even better in a moderate honey-flow; but in a heavy honey-flow the combination of the extracting-super and comb-honey super, with foundation in the sections, would not be equal to a full-depth extracting-super with drawn comb for the prevention of swarming. One of the secrets of swarm prevention is *drawn* combs placed on the hive when the bees need it for room, and *before* they start building cells. The giving of a half-depth super of drawn comb and a super of sections might answer for a few days; but when the extracting-combs are fairly well filled, the bees might hesitate a little before drawing out foundation in the sections; and that hesitation might cause them to start preparations for swarming. The matter can be helped a little by lifting the super of extracting-combs when it is partly filled, and putting the sections under. But if the extracting-combs were old, the bees might darken the combs in the sections slightly. In using extracting-combs in connection with sections, the former should be almost new—clean and white.—ED.]

Preparing for the Next Season's Increase in September

My apiary of 125 colonies is located forty rods from our residence, with an orchard on the north and a building at the west, so that there is good protection on these two sides. The bees have always wintered well in this place, but I always make sure that each colony has plenty of stores and that they are in prime order in the fall. Last year I put 80 colonies in the cellar and had 45 packed on their summer stands for the purpose of making increase the following season.

Since keeping bees I have made my increase by selecting a strong colony having a young prolific queen of the previous season's rearing that has been tested long enough so that I know she is prolific. After choosing a number of such colonies for increase the next season I feed them during the month of September enough to insure brood-rearing until I have to provide second brood-chambers and combs to keep them from swarming. In the mean time I feed some of the colonies that I expect to put into

the cellar enough so that they will be sure to fill and seal five extracting-frames.

About the last week in September I take the upper brood-chambers off the prepared colonies and shake the bees in front of their hives and give them the extracting-supers each containing five combs of sealed honey, prepared for them as stated above. Then I put four quilts on top of the escape-board, then another empty super which I fill with very fine chaff. After this I fasten two-ply roofing-paper around the hive, with four cleats, allowing it to extend above the top far enough to put in some more chaff. Then I fold down the paper; and, lastly, tie a square of paper over all with a piece of cord.

Colonies so prepared winter safely and come out in the spring so strong that I can build them up to three colonies by the 15th of June strong enough to store honey in the supers. Bees thus treated seldom make any attempt to swarm, but will work nicely all the time.

Yorktown, Ind.

J. W. DAVIDSON.

Experiences of a Sixteen-year-old Beekeeper

I am only sixteen years old, but have kept bees for two years. Three years ago last fall my father bought a colony of bees in an eight-frame hive. In the following spring, when the bees had begun to fly, a beekeeper from a neighboring town visited us and showed us how to open the hive, how to inspect the combs, and how to find the queen. He also told us that we might expect the bees to swarm very soon, and advised us to purchase of him one of his twelve-frame hives, and transfer the bees into it, explaining that they would be less likely to swarm from such a large hive. But they evidently had contracted the swarming fever before we changed the hives, for they soon swarmed. A little later they cast a second swarm. We failed to hive either of these swarms, because we were not at home. Probably because they were weakened by excessive swarming, the bees failed to store any surplus honey in the super that year, though we took out two full frames of honey from the brood-chamber, and packed the two spaces on the outside with dry leaves, using division-boards.

The bees came out the next spring in excellent condition. My father, a little disgusted at securing so little honey, turned the bother of the bees, as he called it, over to me for the following year. I studied the A B C and X Y Z of Bee Culture through many of the long winter evenings, and soon had the "bee fever."

That year, 1911, was well known for its long dry spells. The beekeepers in this locality not only failed to get a surplus, but were obliged to feed their bees in order to keep them from starvation during the following winter. Many of the old-timers here were surprised when I told them that I had taken off ten pounds of section honey, and about twenty-five pounds of honey in frames, besides securing a fine swarm, and that I had left honey enough to winter the bees.

The next year, 1912, I secured 162 marketable sections of honey and 20 lbs. in large combs, all from my twelve-frame hive. My smaller colony came through the winter in bad shape, but built up in time to gather enough for winter, and a small surplus besides.

In my comparatively little experience I have found large hives to be the best. The bees seem to winter better, breed earlier, build up faster, and are stronger in numbers when the flow starts than the bees in smaller hives. I would rather have the twelve-frame hive, standard, than the eight or ten. There is less swarming, and what swarms do issue are large ones. Perhaps an older beekeeper could subdue swarming entirely with the hive I use. The only objection I have to the twelve-frame hive is that two bee-escape boards must be used side by side, instead of one, but this is a small matter. My super holds ten rows of sections, four in each. I

have used both the 4 x 5 and the square section; but I like the tall one better, and shall use it entirely next year. In the sections I use starters, but full sheets of foundation in the brood-nest in order to avoid drone combs. I gave most of my honey away, but sold some at 25 cents a pound, and cleared about \$10.00.

ADOLPH C. KROLL.

Northampton, Mass., March 10.

Why the Bees Die that Accompany the Queen

What causes the bees, accompanying a queen in shipping-cage, to die while being introduced? I have gotten of you three queens this summer. In the first case not a bee died. With the second about one-third of them died after the cage was put in the hive during the time the queen was being released; but the queen was all right so far as I know. With the third queen, about half the bees died in the cage after being put in the hive; and, fearing the queen would die, I released her. She was favorably received, but died inside of 24 hours. Have you had such experience?

Asheville, N. C., Aug. 2.

O. BROMFIELD.

[As a general rule a queen-bee will stand longer confinement in a mailing-cage than any of her attendants. Whether this is due to the fact that she is more vigorous than they, or whether it is because they feed her and thus use up their own vitality, we can not say. The probabilities are that bees in the hive during the interim of confinement feed the queen new honey when they would not feed her attendants. The candy in the cage becomes hard, and, unless usable to the bees, it might cause them to starve; while the queen, favorably received by some of the workers of the hive, would be lavishly fed. It is a well-known fact that the bees accompanying the introduced queen will die, as a general thing, before she is released.—ED.]

Uses for Propolis

Having occasion last spring to graft a couple of fruit-trees I got together my tools, but could not find the grafting-wax. After a search I found a lump about the size of a base ball. Being a little hard I warmed the wax, and worked in a little linseed oil. When the weather warmed I noticed the bees apparently helping themselves to the wax around the grafts, so I lightly touched it on top with a little carbolic emulsion that I happened to have left after treating cabbage and cauliflower for root maggots. Some weeks later, on looking through my tool-box I found a ball of grafting-wax intact. Then what was it I had used for grafting? Propolis, and it worked finely. Since then I have used it thinned down with linseed oil for painting wounds when pruning fruit-trees. It also makes a good tanglefoot for flies if warmed and thinned with molasses; then spread it on manila paper.

GEORGE H. BEDFORD.

East Stroudsburg, Pa., July 26.

Wintering in a Room Kept Cool with Ice

Although I am a beginner with bees, I will give here my experience in the past winter. I have six colonies which I have been wintering in a cooler used for butter in the summer. I placed the hives on a board about two feet from the bottom floor, and have left the entrance open the whole width of the entrance of the hive. The temperature has been around 28 to 30 degrees most of the time. The colonies all had a good supply of honey gathered from the field. Out of six hives I do not think that I lost over two quarts of bees that died from old age.

The cooler is cooled artificially, although in the fore part of the winter there was no ice in it. But about the middle of February the temperature was a little higher—about 32; so we got the ice into it,

and it then kept just 28 degrees for weeks. The room is 8 x 10 x 7 ft. There are four spaces between the outside and inner wall, lined with good building-paper. There is a cool-air inlet at the bottom, and an outlet at the top four inches wide by the whole length of the cooler, with a trap-door at the inlet and one at the outlet so as to open and close as the temperature goes up and down. The outlet from the roof runs up high enough so that there is a good draft. The inside of the cooler is always very dry.

Malone, N. Y., March 17.

J. N. VASSAU.

Another who Winters Bees in Cold Storage

I sold a colony of bees to Mr. Henry Schneider, of Pottstown, last fall. He is treasurer of a cold-storage plant, so he put the bees in cold storage in a room where the temperature is kept at 32 degrees. They weighed 56 pounds in the fall. He weighed them Jan. 4 to Feb. 24. They consumed 3 pounds of honey in that time. We took them out March 15. Then they weighed 49½ pounds. They came out fine and lively.

W. B. REITMEYER.

Pottstown, Pa., April 2.

[Wintering bees in cold storage is rather startling. In both the above accounts it appears that the air was fresh and dry. These experiments do not prove, therefore, that a temperature in a bee-cellar below 35 degrees does no harm.—ED.]

Queen rearing; No Difficulty in Getting Cells or Virgins, but Can't Get Them Mated Fast Enough

We have had no trouble to get the cells and to hatch the virgins; but when it comes to getting them mated, it's a different proposition. I notice in GLEANINGS where you say that your basswood apiary will produce 3000 queens besides its full quota of honey. I should like to know how you can produce and mate that many queens from a yard and still get its full quota of honey; for by any system of mating that we have used, we have always found that it takes considerable strength from the bees to make the nuclei and mate the queens. Do you still use baby nuclei? I thought I saw in GLEANINGS a while back where you claimed that the two-frame nuclei of standard size was the best, and that the babies were too small, troublesome, and fussy. Now, to take two frames of brood, bees, and honey from a colony here just before a honey-flow weakens it so it will not store as much honey as it would have by several pounds. I have had no experience with the baby nuclei; but if they're a good thing I might consider adopting them provided you could make them to dovetail in with the Danzenbaker hive. We have used mostly, to mate our queens, two frames divided off to one side of a colony with entrance in the rear; but it leaves the brood-chamber of the main colony too small, besides weakening it somewhat to get the nuclei started, and interfering with uniform storing in the super above. The best method that we have found to mate queens is in connection with increase, when we want to fill up empty hives. Just divide the hive half and half with one entrance in the front and the other in the rear, and put two frames of brood and bees and honey in each half with a ripe cell, or a virgin.

Now, I had thought that, if you could make us a combination nucleus mating and shipping box, of two and three frame capacity for the Danzenbaker frame, then that, together with our divided empty-hive system in connection with increase, might be the best systems for us to adopt. Then by one system we would be getting increase and queens, and by the other we would be getting salable nuclei and queen

We should like to know how you mate your queens so inexpensively, and also to have your advice as to

the baby nuclei, and how best to mate queens in large numbers, as we have been literally swamped with orders, and could have filled them all but for our mating troubles.

We should like to have a system of mating by which we could secure our full quota of honey, or nearly so, and still get our queens mated.

LATSHAW HONEY CO.

Carlisle, Ind., July 30.

[This subject of mating is a science or a trade in itself. In the first place, for the rearing of drones you must have queens *two* years old, of fine stock, and give them drone comb every now and then. These colonies should never suffer from want of stores; or rather, we should say, after the season for honey coming in stops they should be fed *gradually* and *continuously*, otherwise the bees will kill off the drones. A drone-raising colony is a good deal like a cell-building colony—both must have a continuous supply of nectar or a syrup. For feeding we use about two parts of water to one of sugar in a Boardman feeder, all the holes soldered up except one or two.]

With the twin baby nuclei you can mate more queens for a given number of bees for a given amount of help than from the same number of full-sized two-frame Langstroth nuclei. It is less trouble to introduce virgins to the small number of bees; takes less time to find the queens, and less food or syrup to take care of them. But one trouble with the baby nuclei is that queens must be taken out as soon as the queen begins laying. Unless you can have your orders regulated to come in just as fast as you can raise the queens, you must arrange to have the queens as fast as they begin laying in the baby hives kept in larger nuclei. This is so inconvenient that many queen-breeders prefer full standard Langstroth frames, two in number, for a nucleus.

We do not believe it practicable to make a combined nucleus and shipping box, as their function is so entirely different. For your purpose we think it would be more satisfactory for you to have two-frame nuclei, either in a single box or two nuclei in an eight-frame hive-body with a close-fitting division-board between. The entrances should be at the opposite ends of the hive. Such nuclei have the advantage of combined heat, and will hold the queens until you can use them for orders.

You might find it a little more satisfactory to come here for a day or two and talk with our men. We have no trade secrets but that we are willing to give to the public, and should be glad to see you or any of you at any time.

We use both kinds of nuclei for mating queens—the twin babies in the yard where we raised queens only, and the full-sized two-frame Langstroth (two in an eight-frame hive with a tight-fitting division-board between), at our other yards where we raise queens, nuclei, and bees for pound packages. The full-sized nuclei can be used for the nucleus trade, and sometimes they will furnish one pound or half a pound of bees. In good seasons the nucleus frames at our yards are extracted, as queen-rearing operations can not go on in a nucleus where the queen is honey-bound. When the baby nuclei get overfilled with honey we take out one frame of comb and put in an empty one and hold the filled one as a reserve, to be used when needed later on.

You do not understand how we can get honey from an apiary where we are raising queens from baby nuclei. Easy enough. The cell-builders and other colonies held in reserve for cell-building purposes must be strong. Such colonies will produce honey the same as any strong colony. Some years, like this season, it is not necessary to feed them any appreciable amount. This season honey began coming in almost from the time of fruit-bloom to the close of sweet clover, which is usually our last

supply of nectar. Cell-builders will swarm unless they are kept down by extracting, and hence the colonies at our basswood apiary were extracted. They were thus able to produce their full quota of honey.—ED.]

The Cheapest Way to Ship Bees Long Distances

I have about 100 colonies of bees; and as I can not sell them here for as much as I can get for the honey that is in the boxes I am taking the honey from them.

I am going to move back to Pennsylvania, and thought it possible to save the bees and express them through. My idea is to make a box, say about seven feet long, out of light material, and divide it into about 18 compartments, five by five inches; put in a pound section of honey for the bees to feed on, and put the queen with, say, two or three hundred bees in each compartment. On arriving in Pennsylvania I contemplate purchasing enough bees to take some racks and put in the new boxes in which I place my bees when taken out of the box in which I ship them. Of course I shall expect to feed the bees through the winter.

Hamilton, Mont., Aug. 8. C. A. MARKSBURY.

[Your plan of expressing bees back to Pennsylvania in long boxes we do not think would be practicable. You would have difficulty in uniting them to other bees on arrival in the East. Would it not be better for you to advertise your 100 colonies at a low price, sell them if possible, and take that money to buy bees in Pennsylvania when you go back? Your express on such packages of bees would be considerable; and our experience convinces us that many if not most of the bees would be dead on arrival at destination for this reason:

Combs in the sections will not stand hard banging; and the result is that they would be broken out and many of the bees in bad shape. It would be much more practicable for you to shake your bees into 3-lb. packages, as was illustrated in GLEANINGS in the April 15th issue. We have had phenomenal success in shipping bees this way, but found it necessary to use a bottle of water in connection with the candy.—ED.]

Early Cutting of Alfalfa Means Less Tonnage of Hay

The reason that the farmers of Colorado cut their alfalfa before blooming is because their customers, the dairymen, want it that way, claiming it is a better milk-producer when cut before it blooms. No doubt Mr. Turner could induce some of his neighbors to let their alfalfa go to bloom by paying them to do so. Cutting alfalfa before it blooms gradually reduces the tonnage, and eventually kills the plant altogether.

Glenrock, Wyo., Aug. 22. J. E. HIGGINS.

Wintering Surplus Queens in Nuclei

I find it a good practice to winter over a number of nuclei to provide for any loss of queens that may occur in the apiary; and if there should be no such loss, these nuclei serve a good purpose in strengthening up weak colonies in the spring. They are nice, also, for mating early queens, or they may be left to grow into strong colonies for the buckwheat flow. Ithaca, N. Y. E. L. DRESSER.

The Connecticut Foul-Brood-Inspection Law

I have read your editorial note regarding our apiary-inspection bill. The original bill asked for an appropriation of \$1500 annually, but this was reduced one-half by the appropriation committee.

New Haven, Ct., July 30. W. E. BRITTON.

Our Homes

A. I. Root

Know ye not that your body is the temple of the Holy Ghost which is in you?—I COR. 6:19.
Wash ye, make you clean.—ISA. 1:16.

KEEPING THESE GOD-GIVEN BODIES OF OURS
IN GOOD REPAIR.

Terry and I have a pleasant challenge, one with the other, as to which one will live to be a hundred years old. Now, we are both professing Christians; and in our teachings, if we do not honestly own up when we get sick, we shall not be living up to our profession as health teachers or as followers of the Lord Jesus Christ. Doctors and professional nurses, if they wish to be consulted as authorities, ought to be very careful about getting sick. If my good friend and neighbor Terry should get sick down would go his teaching, or at least they would go down a little way. Of course, he does not charge any big fee for his instructions, and, in fact, he does not charge any thing, so all his healing is, to a certain extent, like that of the great Master, who did his work when on earth "without money and without price." Terry must *not* get sick; in fact, I have felt sure the great Father would indorse the great truths Terry is giving us, by giving him health. Well, with this preface I have made another great discovery. It may be new to some of you, at least, as it was new to me.

To be honest, I do have spells of indigestion; and I had such a spell lasting several days in July. I first cut off every thing sweet. Then I tried going a little hungry; but the fermentation in my bowels did not let up until I had several meals of pure lean beef on the old Salisbury treatment. This got me in better shape, as it always has done. But still I had the bad taste in my mouth when I got up in the morning. When my digestion is real good my mouth is always sweet and clean—like a baby's, for instance. Perhaps one who is 74 years of age can not expect his breath to be as sweet as that of a baby; but I think it ought to come somewhere near it.* Well, when my teeth needed some repairs I at once went to a dentist. If we are going to chew every thing until it is liquid or semi-liquid we must have good teeth. This dentist is a

new one, or new to me. He is a young chap, and I think he is pretty well up to date. The first thing he said when he looked into my mouth was, "Mr. Root, when did you clean your teeth last?"

I replied, "My good friend, I am ashamed to say that I forgot to clean them, as I fully intended to do, before I started to come here; and, to tell the truth, I am afraid it is some little time since I gave my teeth a good brushing." Mrs. Root keeps scolding me, and usually brings me my tooth-brush, tooth-paste, and a dish of water on Sunday morning before I go to church, saying that I ought to clean my teeth at least every Sunday morning since I insist on refusing to clean them once or twice a day. Well, the dentist went on to say:

"Mr. Root, I know you will excuse me when I tell you that, if you let your teeth go in the shape they are now in, it is a wonder if you do not have indigestion. The matter collecting in the cavities in your mouth you can not very well get out with a toothpick. It will begin to ferment over night; and if you chew your food ever so well at your breakfast next morning, this matter from the teeth is mixed with it, and will keep up the fermentation in your stomach and bowels. If you wish to preserve your health, and live to be a hundred years old, as you and Terry have talked about, you must clean your teeth thoroughly every day."

Dear friends, I want to make two apologies right here. James enjoins us to confess our faults one to the other; and while I am ashamed to make the above confession, I think that, under the circumstances, it is my duty, and that it will do good all around.

The other confession is (and I wish to include an humble apology to my young friend the dentist), all at once Satan put it into my head that this dentist, perhaps, had tooth-brushes, tooth-powders, or tooth-paste for sale. I had been to two different dentists and paid them quite a little money within the past year, and neither one of them had said a word about my unsanitary teeth. I said, "My good friend, do you sell tooth-brushes or tooth-paste?"

"Nothing of the kind. You can get the best up-to-date implements for the care of the teeth at any of the drugstores."

Somebody has been mean enough to insinuate that dentists would lose a chance of getting jobs (with big pay) if they, like our physicians, should be too vehement in urg-

* Should God in his loving providence permit me to reach the age of eighty or ninety, I am hoping and working and praying to be able to keep clean, pure, and sweet, in body, mind, and spirit. I fear old people oftentimes get to be careless about their dress and personal habits, etc., just as I have been careless about my teeth. I have been scrubbing my body daily, from the top of my head down to my toes, but forgetting, ignoring, and overlooking the teeth and mouth—the "gateway," as we might call it, of every thing taken into the stomach in the way of food to keep up that "storage battery" of health and strength.

ing that "prevention is better than cure." Let us now go back to that bad taste in my mouth.

I think I have mentioned that, in eating my apples, I greatly enjoy a little bit of cheese—say half an ounce. Well, when I had that severe spell of indigestion, each morning when I awoke I could still taste the cheese in my mouth. I told Mrs. Root that I believed this had something to do with my spells of indigestion, and that I would try dropping off the cheese and eat only apples. Well, it did stop the "cheesy" taste; but there was still a bad taste in my mouth that I knew was not right. Now, what do you think? When I ate the cheese, even though I chewed it until it was almost liquid, it got between my teeth and remained there all night, and, of course, it resulted in a bad cheesy taste in the morning. I hope you will excuse me, dear readers, for going over this matter so much in detail; but my "great discovery" comes in right here. I went to the druggist and got the best up-to-date tooth-brush he had. Then I got the very best tooth-paste, and followed directions. I ate cheese, all I wanted, with my Red Astrakhan apples—seven or eight good big-sized ones—and I can honestly say I never enjoyed any food more in my life. I never enjoyed the most elaborate dinner more than I did those Red Astrakhans and Yellow Transparent apples. Before I went to bed I scrubbed my teeth and mouth most thoroughly. The next morning there was no bad taste whatever, and my digestion now is just perfect. I can eat raw tomatoes with sugar, pepper, and vinegar, or with sugar and cream for dinner, and they do not trouble me a bit. I eat peas and beans in moderation, and green corn; and I am satisfied that at least a great part of the improvement has come from thoroughly cleansing my teeth and mouth, finishing up with plenty of pure soft water.

May God be praised for our dentists and physicians who are not only able but willing to speak the plain truth when caring for these bodies of ours.

Let us not be weary in well doing; for in due time we shall reap if we faint not.—GAL. 6:9.

I have been reading the Home papers with great interest this past year; and as I need some advice I thought perhaps you could help me.

My father was a beeman in Barry Co., Mich., and took GLEANINGS as long as I can remember, and I used to read the stories written by "Rambler," with great interest when a small lad.

When I was twenty I started for myself and hired out to work on a farm for a neighbor, for, like most boys, I thought my own father's business was not as good as that of some one else. I had no bad habits; and as I got good wages I soon saved enough

to make a first payment on a little farm, and soon had some stock, chickens, and bees. I was thrifty, and every thing turned into money that I took hold of; but I was very discontented in living alone; and as every one kept telling me I ought to get a wife I soon grew to think so myself. I gave my heart to God, and have tried to serve him in my every-day life, and I don't know that I am doing right in writing this, as he has never failed me; and as I have never yet gone hungry I have no proof that I ever shall.

But to go on with what I started to tell you. I had almost paid for my little farm when a cousin came to visit me from the East, and wanted me to go back East with him and see some of the world; so, as I had a chance to exchange my farm for a cheaper one that would put me out of debt, and give me a little to the good, I made the deal, sold all my personal property, and went to New York. I liked the East, and decided to buy a cheap farm in New York; but when I came to sell the farm I had in Michigan I found that the title was not good; and as the party who gave me the deed had been dead for some time I had no redress and lost one thousand hard-earned dollars. I then had left only about two hundred dollars, and I decided to hire out to a dairy farmer, as they pay the best wages in the East. I think I overworked a little, for by the middle of September I was sick in bed under the doctor's care; and when I got out the doctor said I must not work at hard work for some time. This took all my hard-earned summer wages, and I was not in shape to work at dairying any more. I always thought I should like the jeweler's trade, so I began to repair clocks and watches. In the mean time I met and married my wife; and after buying our furniture I had very little left out of a declining bank account.

Last August there came twin boys to our house; and through the expense of sickness I have used all the small bank account, and have to get along on what I make from day to day. I now have the trade very well learned, and a very good line of tools; but this town is too small to keep a jeweler, and I have no cash to move to a larger town.

My chickens are doing fine, but I have only a small flock.

There seems no way for me to get where I can stand on my feet, to use a common expression, and I do not see my way clear in the future. Although I am not in debt to any one, I am just to the end of my cash and very little work. As you used to work at the jeweler trade, and have had a wide range of experience, I thought perhaps you might have a word of advice to offer.

Trusting that God will direct you to give me the proper advice, I am yours cordially,

New York.

F. S. C.

After going over the above letter several times I decided that this thing that got our friend into trouble—that is, if he really *is* in trouble—is the habit of becoming discontented. His losing his farm because the title was imperfect points a moral. When you buy property, have some competent attorney examine the title, in order to be sure it is all right. My opinion is (without consulting an attorney) that his title could have been made good, even though the one he bought it of was dead. Of course, circumstances might prove otherwise. Our friend did a very wise thing in getting married, and I think, also, the great Father above "did a wise thing" in sending the twin boys to that humble home. Below is my reply to his letter. I decided to put it

in print because it may encourage others who are situated in a similar manner. Do not be in haste, dear friends, to think you can improve your condition by moving to some other place.

My good friend, while I thank you for the high compliment you pay me in deferring to my judgment, I fear I may not be able to give you the advice you need. First, I am glad to know that you fear God and are trying to keep his commandments; and if you make it a matter of prayer as to what you shall do, I am quite sure you will be directed right.

Yes, the greater part of my life was spent at the bench. When I was climbing down the ladder after putting up my sign as watchmaker and jeweler, a man gave me a job, and I have never been out of work since. One reason is that I would repair any thing, or do any thing to help needy people. I tried hard to make myself useful to humanity. Now, if you are in a small town I feel sure if you try earnestly to do every thing faithfully that comes in sight to help your fellow-man you will find plenty to do, and ultimately get your pay. A great many times I know I spent perhaps hours at a time, and didn't feel that I could conscientiously charge what the job was really worth, especially for something that belonged to poor people; but that sort of work paid eventually. I got a reputation for being reasonable, and being Christianlike in making my charges. In a little while I had to hire help, and this thing has been going on for sixty years. Sometimes I feared I was reckless in trying to help people; but my reward came sooner or later.

Ask your wife if I am not right in thinking you should stick to your trade, where you are. With the help of the chickens, I am sure you will get enough to do, and will be better off than if you think of changing your location.

A. I. ROOT.

GOD'S KINGDOM COMING: DOUBLING UP THE COUNTRY CHURCHES.

We clip the following from the *Cleveland Plain Dealer*:

A PRACTICAL EXAMPLE.

In an effort to make rural churches unite, to the increase of their membership, economy in church management, and the financial advancement of their pastors, a monthly magazine is collecting statistics as to the number of churches in small towns. The investigators have taken two widely separated States of the Union as a field for their work, and the figures are interesting and suggestive.

Almost every little village that could support one church comfortably has from three to five which only by a stretch of the imagination may be said to be "supported" at all. A handful of people in each edifice, a hopeless, poverty-stricken preacher, a treasury with the minus sign in front of it—these are common conditions.

That such conditions are not irremediable, however, has been shown by a little town in Missouri; and the attention of these investigators might well be directed to that little town. Its name is Alma, and it is to be found only on the largest maps, for its population is only 319. Yet, not so very long ago, Alma was struggling to support four churches. These congregations were Methodist, Baptist, Presbyterian, and Congregational. Last year they just got together and agreed to bury their sectarian differences. They united in one congregation, chose the most convenient church edifice, and hired a minister to preach the gospel to them.

They are doing well in that church, they say. New members are baptized by whatever method they may prefer. Old members are not required to resign their allegiance to their own creeds or articles of faith.

Doubtless the brethren do not agree on certain doctrinal points, but they dwell together in unity for all that. Nobody's theological toes are stepped on, and they are out of debt, and their pastor has a living wage, promptly paid.

"A little child shall lead them," says the Scripture. Perhaps little Alma may yet lead the two and seventy sects into the unity that has been the dream of many Christians.

I read the above with much interest, because in one of my wheel-rides a few years ago it was my privilege to pass through the little town of Alma, Mo. I wonder if some good brother or sister who lives in Alma or somewhere else can tell us what they call the new church that was made up of Methodists, Baptists, Presbyterians, and Congregationalists. I have seen several attempts of this sort, and down in Florida they have been quite successful. The only difficulty was in deciding on the name. I think in one case they called this the Union Church. May God speed the work of doubling up.

REMEMBER THE SABBATH DAY TO KEEP IT HOLY.

The following, which we clip from the *Sunday School Times*, explains itself:

WILBUR WRIGHT'S ANSWER.

Today is a sabbath unto Jehovah.—Ex. 16:25. The Wright brothers, the famous aviators (of whom one died in 1913), are clean-limbed and clean-minded. From their father, good old Bishop Wright, they inherit two sterling traits—character and a shrewd business sense. When Wilbur was at the high tide of his first foreign success, and was acclaimed everywhere as "the emperor of the air," the king of Spain came to see his machine. An orderly approached and said, "His Majesty would like to see you fly." "I am very sorry," was the reply, "but we never fly on Sunday."

It is especially interesting to me, because I was so well acquainted with our good friend Wilbur Wright, his father (Bishop Wright), and the rest of the family. God grant that we may have at least a few men left who are not afraid to stand up before men, even kings, and confess their respect for God's holy word.

"PEACE ON EARTH, GOOD WILL TO MEN."

We clip the following from the *Commoner* of May 23. Can not the readers of GLEANINGS give it a hearty amen?

THE NEW DREADNAUGHT.

"Ever since the earliest days men have been building ships. They are still building them; but the ship we are planning is different from the others. Its compass is the heart; its shells carry good will; its missiles are projected by the smokeless powder of love; its captain is the Prince of Peace. I ask you all to drink with me to this new battleship—the ship of friendship. No target can withstand the shots that friendship sends abroad."—Mr. Bryan's toast to the "Ship of Friendship," in bidding good-by to the foreign peace delegates at the John A. Stewart breakfast given in Washington, May 18.

High-pressure Gardening

BARREN CORNSTALKS, ETC.

Just now the whole wide world is interested in eliminating the *hen* that does not lay eggs and the cow that does not give her share of the milk, etc. On page 578, Aug. 15, I have given you a glimpse of my patch of sweet corn. Well, during the severe drouth during the fore part of August our two cows gnawed down their pasture lot so that it was very desirable to give them some green food to keep up the flow of milk; and as their pasture lot was close up to the sweet corn I began cutting out the stalks containing no ears. There were three if not four varieties of sweet corn—Golden Bantam, Black Mexican, and Stowell's Evergreen. Almost every stalk of the Golden Bantam contained one or more ears. But with the two others I found one and sometimes two stalks, quite often, in a hill, with no ear on at all; and I went over the whole patch, cutting out these useless stalks. One reason why I took the time and pains was because I wanted to study the matter. First, I decided the barren stalks were mostly found where there were four or five stalks in a hill, indicating too heavy seeding. But this does not explain it all. Owing to the bad weather I have mentioned, there were many hills with only one or two stalks; and several times when there was only one great stalk in a hill, ten feet high or more, there was not an ear of corn nor a sign of an ear. I think I may safely say that in that patch of sweet corn ten per cent of the stalks were barren.

I once heard Professor Holden say in an address that your seed corn should be grown and saved in a little patch by itself, and that you should take great care to cut every barren stalk before the tassels could shed their pollen. In other words, he claimed that these barren stalks were the result of letting barren stalks stand in the field the generation before. Now, if this is true it is an exceedingly important matter. I have for years gone through our cornfield and selected my ears for planting. A neighbor of ours who got some of our seed corn because his was poor, said he got 49 healthy plants from 50 kernels of corn that I furnished him. Now, this is all well and good; but what is the use of having corn that will grow if ten per cent of the good thrifty stalks bear no corn? And if Mr. Holden is right, we can not afford to get our seed corn out of any cornfield. Our seed must be grown in a piece of corn remote from other cornfields, with the barren stalks or barren tassels carefully cut out. It is too

late now to do any thing this year; but shall we not make careful preparation to have some seed corn next year that will produce one or more ears on every stalk? A neighbor of mine has just told me that he found more barren stalks in the field this year than in any other season he could remember. Is it possible that the cold and unfavorable weather at planting-time had something to do with it? Of course, the above refers particularly to the saving of seed for field corn. I believe the Boys' Corn Club has been discussing this very matter; and these boys are more careful than their fathers have ever been to have the very best seed that care and skill can furnish.

Later.—Since the above was dictated I have been out among our field corn; and the stalks with no ears are not any thing like as frequent as with sweet corn in the garden. In fact, I do not think there are more than four or five stalks in a hundred with no ears on. Where there are too many stalks in a hill the few spindling stalks are apt to be without ears; but this shows plainly that it is the result of overseeding—too many stalks in a hill. But in our sweet corn several times I found four great lusty stalks in one hill, and almost nothing in sight to indicate where the ear ought to be. I think it must be the strain of seed, for our Evergreen sweet corn is worse in this respect than any other one of the three kinds planted on the same piece of ground. Another thing, the field corn this year was planted with a drill, aiming to get a stalk of corn about once every foot. Perhaps such planting would give fewer barren stalks than three or four stalks in a hill, say four feet each way; but by the latter plan, when cultivating both ways we find it much easier to keep out the weeds—that is, much less hand work is required.

SELECTING THE SEED CORN.

The above reminds me that, about the time this reaches our readers, they will need to be selecting corn for planting next year. Do not listen to the old farmers who insist that you pick your seed corn out of the cornerrib. A man of experience may, I grant, pick out better ears simply by the looks as they lie in the crib; but neither he nor any one else can tell by looking at the ears the circumstances under which they were grown. The following, which we quote from the North Carolina Bulletin on the Selection of Seed Corn, touches the point:

Go through the field, row by row, marking those stalks which come nearest your ideal, remembering that if a desirable plant is anywhere near a barren

stalk or one of decidedly undesirable qualities to leave that plant unmarked, because it is in "undesirable company," and has become contaminated.

Probably you think this will not pay. The Corn Club boys think it will pay, and are proving it by growing three and four times as much corn per acre as their fathers.

Later.—The *Ohio Farmer* for Sept. 6 has a most excellent and timely article on selecting seed corn.

They suggest that the ears for seed should be selected before the corn is per-

fectly mature. Go through the field as has been directed; and when you find an ear with environment and every thing else according to your ideas, break down the tassel just above the ear. This is quicker than tying a piece of cloth about the stalk as I have suggested. Then just before the corn is cut (or, indeed, it may be done while husking, providing you have some careful men who obey orders) sort out and preserve these selected ears.

Health Notes

HEALTH FOODS, CEREALS, ETC.

My good friends, how many different kinds of cereals and health foods do you suppose there are on the market in the United States? Well, in my hand I hold a report from the Connecticut Experiment Station in regard to food products and drugs. They enumerate something like one thousand different kinds of flour, cereals, health foods, etc. Among other things there is quite a good-sized list of diabetic foods. In fact, I do not know but half of them are special foods for the treatment of diabetes. Now, this report is entirely unbiased. No one can well maintain that this Connecticut station is prejudiced in its reports and statements, and the report is just about what I expected.

While many of these health foods are really good and wholesome, the price is in almost every case excessive and often exorbitant. Let me say again what Terry and I have so strongly urged: Get some good nice wheat directly from the farmer, just after it is thrashed. Then have a little hand mill, or, better, one run by power if your family is large enough, and make your own graham flour, cracked wheat, etc. This health food, direct from "producer to consumer," is more wholesome, I do believe, than any thing else you can find in your stores and groceries; and you can easily tell how much cheaper it is by weighing the grocery cereal and then weighing the wheat and counting the cost. Now, aside from the matter of cheapness, a great part of the health foods are not at all what is claimed for them in the advertisements. The gluten breads and gluten meals, some of them, are really not suited for a diabetic patient; and when you come to the so-called meltose syrups they are no better than maple syrup or good honey, while the cost is ever so much more. Macaroni, noodles, etc., are probably wholesome enough, but they are tremendously expensive compared with cracked wheat. Terry buys his oatmeal, etc., in quantities, and gets them at very

low rates. You can buy oatmeal by the hundred pounds at a very low figure indeed compared with what you pay at the groceries when you buy it in embellished paper packages. For an illustration, the breakfast foods to be found in our groceries cost from 12 to 65 cts. per lb.; and the farmers who grow the wheat get from 1½ to 2 cts. per lb.; and the wheat just as it comes from the farmer's field is ever so much better to sustain health and strength than any wheat product you can buy, that has gone through the mills to make it into flour, etc. Nuts are a good and wholesome substitute for meat; but the nut preparations on the market cost awfully compared with the expense of grinding the nuts in this same little hand mill. Allow me to copy a little. A manufacturer of malted nuts claims as follows:

Cow's milk is an excellent food for young calves, but it is a very poor food for a human infant, and still less adapted to adult human beings. Thousands of persons have discovered for themselves its unwholesome properties. Malted nuts supplies the place of cow's milk as a liquid food. Its composition is similar to that of milk.

In regard to the above, this bulletin says:

Its composition is not "similar to milk," even considered on the dry basis, as it contains much less protein, fat, and ash, and much more carbohydrates than dried whole milk. Such extreme and unfair statements regarding such a useful food as milk should not be allowed to pass unchallenged.

This food bulletin contains about 100 pages in regard to false claims for foods and drugs put on the market for sick people; and it is altogether a tremendous protest against the fashion of "robbing sick people" by holding out extravagant claims for special food products and drugs, including various wines.

TRUE SCIENCE VERSUS SUPERSTITIOUS NON-SENSE.

There are a lot of old people who probably will never give up their notions about planting things in the right time of the moon, about Friday being an unlucky day, the No. 13 hoodoo, nailing up a horseshoe to

bring good luck, and a whole lot of other things along that line. These good people, honest as the day is long, do not seem to be able to distinguish between true science and nonsensical notions. Just a few hours ago a man whom I have known for years attempted to show me how a peach-tree crotch enabled him to find water. As he walked along over the ground the switch would turn down at certain places. I insisted that it turned because he twisted it with his wrists. But he declared that the crotched stick was what made his wrists twist, and he may have been honest about it. But now listen: When asked why it would not work the same way in *my* hands, he said it would not work with everybody. When I asked why, he said there is more electricity in some people than in others; and this seems to be a widespread notion among many of the older people. Our boys and younger men who are getting to be experts in electricity would laugh at such an idea. It is true that you can put more electricity into one man than there is in another by standing him on a stool with glass legs; but while he is standing on the ground the electricity very quickly seeks an equilibrium. Then this man explained to me how a switch would go down just three times and no more until he changed his position. Then he would do the same thing again when he crossed an underground stream.

I wonder how many of our readers remember the planchette board that made such a stir in the year 1868. Many good people declared that the senseless piece of wood would spell out words. In the same way many good people insisted that the forked stick goes of itself because they unconsciously twist their wrists. Now listen to something more this man told me. He said he could tell the exact number of feet we would have to dig to get water. He does this by setting a tumbler of water on the ground, and hanging in it a button suspended on a thread inside of the tumbler. Pretty soon the button will commence swinging—that is, if the “water-witch” has hold of the string. It will then bump up against the tumbler just the number of feet one will have to dig to get to the water. And then he told me that just recently the button bumped 62 times, and the man found a bountiful well of water by digging *exactly 62 feet*.* When he attempted to explain that electricity did it, the subject suggested what I am now writing—the strong contrast between real science and humbug science.

* It occurs to me that it must be the “spirits” that make this button pound out the number of feet down to the water—the same spirits, perhaps, that used to pound out answers by means of “spirit rappings” in 1852.

In real science certain processes take place or work exactly alike in the hands of *any* experimenter. God’s agencies are “no respecter of persons.”* Edison has achieved wonderful things by careful study and experiment; and the lines of science are well laid down and established.

As there may be many good friends among our readers who still insist that water-witching is real sense and science, let me explain that some years ago the Department of Agriculture at Washington took the matter up. A number of scientific men went into a field with some of the most skilled water-finders or water-witches, as they are called. Among other tests they tried blindfolding the man to see if he could locate veins of water just the same when led over the route, and he failed, of course, to find where the former stakes were stuck. The two records did not agree at all. The stakes set by the blindfolded man had no relation whatever to those set with his eyes wide open. My recollection is that the greater part of the water-witches decide that, for some unknown reason, it would not work with a blindfolded man; and one good old man came out frankly and acknowledged that he had been deceived all his life in thinking the switch turned down of itself. We can forgive him, even if he had taken money for many long years for locating wells. But another chap, with a different kind of conscience, on another occasion managed to push the bandage out of the way a little so he could get a glimpse of where he was going. Of course the stakes he set tallied. When, however, he was blindfolded in such a manner that such a thing was impossible, he too had to own up that it would not work when he could not see.

The question has often been asked if the switch would turn when walking over a bridge where there is a stream of water. But I think they generally agree that it would not work then. The water must be under the ground.

The way in which people get into ruts or get senseless notions into their heads explains the success of the shameless frauds called electropoise, oxydonor, oxypathy, oxygenator, etc., and the various other things that have been invented for something that has not a particle of sense or science about it. Carrying a lucky stone in your pocket is along the same line. Recently a subscriber sent me a glowing circular with hundreds of testimonials, apparently, of a finger-ring that will cure rheumatism. If the testimonials are not all manufactured, they come from foolish people who imagine the rusty ring wrought

miracles in the way of cure. I hope it is true that the coming generation will not be as easily humbugged by such quacks and absurdities. Educated men and women, and educated girls and boys, at least the

way they are being educated at the present day, as a rule demand sensible reasons before they invest in something that pretends to be scientific when it would not even bear the scrutiny of good common sense.

Temperance

THOSE PICTURES; OUR GOOD FRIEND DOOLITTLE TALKS TO US ABOUT THE PARTNERSHIP EXISTING BETWEEN THE UNITED STATES AND THE SALOONKEEPER.

Dear Mr. Root:—By a strange coincidence I was reading in the semi-weekly *Free Press* the internal-revenue statistics for the fiscal year ending July 1, 1913, when the issue of *GLEANINGS* for August 1st came. I picked out *GLEANINGS* from the other mail, and read the editorials, *Stray Straws*, and then turned to *Our Homes* and the Temperance department, as is my custom. Those pictures took my eye at once, and I said, "How true to life!" Then I turned to the statistics in the *Free Press* (not a temperance paper), and read these facts: "The people of the United States consumed more whisky, brandy, and beer, and smoked more cigarettes and cigars than in any previous period in the nation's history. The returns show that the government received from drinkers and smokers in taxes, \$309,478,000 in the past year—an average of about \$1,000,000 for each working day in the year, or \$16,500,000 more than during the previous fiscal year, which paid about half the government expenses." Then I turned back to the pictures again, when that saloon front riveted my gaze. I asked, "Whose is that saloon?" and the only answer I could find was, "The government's." The building, bottles, liquors, and tobacco may or may not be the saloon-keeper's, but the saloon belongs to the United States government. Let the saloon-keeper try selling those liquors without a permit from the government, which is called a *license*, and see how quickly he will "look out from behind the bars." So we have this: \$25.00 paid for a license establishes a *government saloon*; \$1.10 tax procures from the government a gallon of whiskey; \$1.00 a barrel of beer; this in addition to the cost of production of the liquors. And none of that \$309,478,000 could come into the treasury of the government without some one to sell these taxed and licensed articles.

Now, Bro. Root, is it not plain that the *saloon-keeper* is a necessity in the economy of these United States if you and I are to have "half our government expenses" paid? And is it not also plain that the officials in whose hands this matter of tax and license rests should seek out and urge men to sell, buy a license, and pay the tax, that this revenue may come to us and the rest of the people of this United States? Your company would not hire a man to sell honey unless he sought out customers for that honey. And after the saloon-keeper has paid his license and tax to the government, is he not doing a legitimate business in branching and reaching out that he may get his money back and something for a living? Should we not be willing that he do this when he is so useful to us in paying half of our government taxes? Seriously, Bro. Root, I do not like to see that bright boy in these pictures turned into "The Finished Product," but of late it has looked a little out of place for you and me to be "pounding" the saloon-keeper when, at the same time, we are willingly or ignorantly receiving pay to the half of our proportion of the government expenses through the efforts of the saloon-keepers of our land. If we are honest we must acknowledge that the saloon-keeper fills a niche of no small importance in the economy of the United States government. Surely, from the statistics for this last

fiscal year the revenue from our government saloons almost overshadows that from the tariff and custom-house. Are you equal to some plan to save the boy without materially injuring the amount of revenue we are receiving into the government treasury?

Borodino, N. Y.

G. M. DOOLITTLE.

Friend D., I have a plan—yes, and may God be praised that there is a plan open to us all. The plan is to teach our boys and girls, our old men and women, to "seek first the kingdom of God and his righteousness," and then that "all things shall be added unto you." Yes, those who administer our government and our laws should be taught that, if they will seek first God's kingdom and his righteousness, plenty of money for "revenue," and every thing else will be surely forthcoming.

ONE-THIRD OF THE SALOONS OF OHIO TO BE PUT OUT OF BUSINESS.

We clip the following from the *Wheeling Advance*:

"Law closes 3341 saloons in Ohio; leaves 5144 still doing business."

The above seems too good to be true; but when they come to put on their spectacles and find 5144 saloon-keepers of good moral character I imagine there is going to be more trouble yet, especially if the law is to be strictly enforced, in big cities as well as little ones, as our good Governor declares it shall be enforced. See the following:

SUNDAY CLOSING OF THE SALOONS IN OUR LARGE OHIO CITIES.

I am well aware that it is not a new thing for the brewers and liquor party to make great promises about the "cleaning up" and "law enforcement" they are going to inaugurate. Our readers will also recall what I have said about the efforts of the Baptist Brotherhood to enforce law in Cleveland in regard to Sunday closing. Now, once more please keep in mind that the Governor of Ohio has favored a license law. He thinks it will be a temperance measure; and as he has been most severely criticised on this account he comes out just now in the *Cleveland Plain Dealer* as follows:

"So soon as the State Liquor License Board announces the appointment of county licensing boards I am going to call every county license commissioner to Columbus and talk straight from the shoulder to them," said the Governor.

"First of all, I am going to tell them that the first one of them that permits a violation of license law without taking action against the saloon-keeper who has broken the law will lose his own official head. The law is plain. A saloonkeeper may have his license revoked on a second conviction.

"In regard to Sunday closing, my position is this: The success of the whole license system depends on its enforcement. The people of Ohio expected it to be enforced. Every saloon must close on Sunday, and stay closed. This applies to Cleveland, Cincinnati, Columbus, Toledo, and every other large city, with the same force that it will apply to small towns. Ohio will be as dry as the Sahara desert on Sunday."

I hope Governor Cox will excuse me for mentioning right here that the friends of temperance—at least some of them—have been unkind enough to suggest that the above is only for effect; that, notwithstanding such a strong public statement, they fear things will go on after the old fashion, especially as it seems very evident that the mayor of Cleveland is not in sympathy with Sunday closing.

Now, one reason why I have given place to the above is that our Ohio people may know what the Governor promises to do and is *expected* to do. May God help him to make good his declaration, notwithstanding every thing the brewers and liquor-dealers may be able to bring forward to block the way of the enforcement of our righteous and just laws. Will our temperance friends in Ohio see that there are plenty of printed copies of this declaration, and that they are kept constantly before the eyes of the licensing boards of our wet counties?

WHAT SHALL WE DO WITH OUR GRAPES?

Quite a hue and cry has been raised by way of remonstrance against the work of "temperance fanatics" in their determination to ruin the industry of making wine. What will the poor women and children do? The great ranchers of California have immense capital involved for producing grapes to make wine. Somebody suggested that they should make their grapes into raisins. But, if I am correct, the wine grapes do not make raisins. Here is a suggestion from the *Practical Farmer* that solves the problem. Can't you say amen to it?

THE BRYAN BEVERAGE.

It is scarcely twenty-five years ago that we began to hear and talk about "unfermented grape juice." It was about that time that there were a few places in New York city where the juice was freshly pressed out of Concord or other black grapes, and served to thirsty customers at five cents a glass. We hailed the beginning of this enterprise with a good deal of enthusiasm, expecting that so delicious a beverage was bound to appeal to public fancy, and possibly be the means of powerful aid in the fight against the evils of intemperance. Since the days of that very modest beginning, the industry has grown by leaps and bounds, and the unfermented juice of the grape has become a common and popular beverage.

That it is exceedingly wholesome, as wholesome as it is palatable, is not in the least subject to doubt. At one time it was even claimed (with what justification we have no means of knowing) that the fresh or canned juice of the grape is fatal to the typhoid-fever germs. We know that it is a very pleasant summer or winter drink, and that it requires no special skill to put up a home supply if one has the grapes or can get them. If Mr. Bryan's courageous defy of old-established custom will serve to stimulate the use of and call for unfermented grape juice, and make the substitution of this harmless and wholesome beverage for alcoholic drinks fashionable and common, then he has thereby rendered to the country a service that can hardly be overestimated.

Lakewood, O., March 3. J. D. McCALMONT.

CIGARETTES, AND WHAT THEY ARE DOING IN THIS LAND OF OURS.

I presume our readers have all been shocked by the terrible story of the factory that burned in Binghamton, N. Y., on July 22. Below is a newspaper clipping in regard to the probable cause of that shocking calamity whereby between fifty and sixty women and girls were burned to death:

Some features of the catastrophe were brought out in a statement by President Freeman, of the company which operated the burned factory.

"I was in the office when Mrs. Freeman called to me that there was a fire," said Mr. Freeman. "I ran out on the main floor and saw flames coming out from under the open stairway. Some of our employees are so addicted to cigarettes that, smoking being forbidden in the building, they went out into the alley every hour or so for a puff. I believe one of these, on returning to work, threw his cigarette under the stairway."

The man or boy who smokes cigarettes becomes stupid. His senses are dull; and the cigarette fiends are continually causing fires by their stupidity in cases like the above. The general government is just now leaving almost no stone unturned in the way of prevention of loss of life like the above; but when it comes to whisky and tobacco, and especially the deadly cigarette, it says, "Hands off." Bulletins are sent out discussing habit-forming drugs, but the cigarette is not mentioned. There are millions of money in the manufacture of cigarettes that are to be sold three for a nickel. Nobody disputes the fact as to their bad mental effect on children, and older people, perhaps, to a lesser extent; but comparatively nothing is being done. Why, even the Chinese, in their recent crusade against the opium habit, are going ahead of us. May God speed the day when cigarettes as well as rum shall be handled by our President, and the officials under him, without gloves.

ANOTHER VICTORY FOR TEMPERANCE.

I am glad to tell you that we whipped the saloon advocates soundly. Our county is free from the saloon curse, and I believe it will remain so.

Weiser, Idaho, July 11.

Editorial

"CASH FOR YOUR HONEY AT YOUR DOOR."

DO NOT fail to take advantage of the special offer by N. E. France, as announced in his advertisement on page 20 of this issue.

MR. C. E. PALMER, of Ransomville, Niagara Co., N. Y., wrote us on June 13, "Bees have been killed by the peck in this locality by spraying with arsenate of lead; and it looks now as if little or no comb honey will be secured this season."

EMBARGO ON THE SHIPMENT OF BEES IN IMPERIAL COUNTY, CALIFORNIA.

THE following telegram came too late for insertion in our issue for Sept. 15, and hence we are inserting it here at this time.

On account of prevalence of European foul brood, the bee inspector of Imperial County has quarantined against shipping of bees from any of the counties in the southern half of California into this county. This is an absolute quarantine. Any one contemplating shipping here had better get full information and save expense.

Imperial, Calif., Sept. 11.

J. W. GEORGE.

THE TEXAS FOUL-BROOD LAW INOPERATIVE FOR THE WANT OF FUNDS.

WE are advised by Mr. Wilmon Newell, State Entomologist for Texas, that the last legislature which was in special session in July and August did not make any appropriation for the continuation of foul-brood or educational work. The beekeepers of the Lone Star State are, therefore, without funds for keeping up their fight against bee diseases during the next two years. This is too bad.

CARELESSNESS IN STRAINING HONEY.

THE following statement in a letter to a honey merchant in New York State is right to the point. "I have bought honey this year that averaged about one cupful of dead bees to every sixty-pound can, and there was more or less other foreign matter besides."

A few cans of honey put on the market in such condition will do more to lower the price of honey generally, and to cause suspicion regarding it, than can be offset by all the advertising and painstaking efforts of careful producers combined. Every pound of inferior honey sold hurts the honey business in general, and the careless producer in particular.

OUR COVER PICTURE.

THE view on the cover for this issue shows a part of the apiary of George Zautner, located in the city of Albany, N. Y. Mr. Zautner writes that the honey crop, while it is quite light this season, was very good last year. In 1912 his 72 colonies, spring count, produced three tons of honey.

We are glad to present on page 679 another view of the apiary showing also Mr. Zautner and his family. So far as we can recall, this is the largest crop of honey ever produced right in a city. Are there other city beekeepers who can beat it?

A CORRECTION.

IN giving credit to Professor Baldwin, who assisted us in the preparation of matter relating to honey-plants, in the preface to our A B C and X Y Z of Bee Culture, we gave his name as Eugene G. Baldwin when it should have been Edwin G. Baldwin, of Deland University, Deland, Fla. Both Mr. Lovell and Mr. Baldwin did excellent work in bee botany for the A B C, and we have expressed our acknowledgment to both the gentlemen; but, unfortunately, we have obscured Professor Baldwin's name just enough so his friends do not recognize him as one of the editors in the new work.

INSURING BEES AGAINST FOUL BROOD IN SWITZERLAND.

FROM the *Scientific American* for March 15 we learn that a form of insurance has been in existence for several years against disease (not against winter loss or any other contingency). A few years ago the Swiss Beekeepers' Association decided to establish a system of insurance, to be compulsory upon all the members, of whom there are about 7000, each paying a premium of about one cent a hive. In return for this they are guaranteed free treatment of suspected colonies, with instruction and assistance, and also with compensation to the extent of 75 per cent of the value of hives and combs destroyed by inspectors.

In December, 1909, the Swiss government decided to take over the inspection and treating of diseased colonies, and the Association was thus relieved of the expense.

In 1911 the number of colonies insured was 105,179; cases of foul brood, 114; the expenses, including claims paid, exceeded the premiums paid by 342 francs, or in our money a little over \$17.00—very small loss, surely.

In this country, owing to the fact that disease is more prevalent in some localities, at least, the premium would doubtless have to be much higher than one cent a colony.

FREE BOOKLETS ON THE USE OF HONEY.

THE National Honey-producers' League is preparing to send out to honey-producers free literature in the form of booklets designed to stimulate a demand for honey. The only condition required is that applicants pay their own postage. (See how they may be obtained in the advertising section of this issue, page 20.)

The Honey-producers' League was organized for the purpose of advertising and creating a demand for honey. The way seems to be open by which funds which it has held can now be distributed for the benefit of beekeepers at large in this country. All honey-producers, especially those who sell in a retail way, should avail themselves of this excellent opportunity before the supply of booklets on the uses of honey has been exhausted.

We understand that Mr. France proposes to use the balance on his hands (some \$600) for purchasing and distributing this literature. There will doubtless be a very heavy demand for the booklets, and those who desire to secure them will do well to get in touch with Mr. France at once, before the supply is exhausted and the money is gone. The issuance of these booklets just after the present fine crop of honey has been secured is particularly opportune.

NEW SUPERINTENDENT OF APIARY AT THE MASSACHUSETTS AGRICULTURAL COLLEGE; JOHN L. BYARD APPOINTED.

THE apicultural work at the College is growing so rapidly, and the demands of the beekeepers are becoming so insistent and general, that it has been found necessary to maintain a larger number of colonies of bees in order to accomplish results. This healthy growth is an index to the interest in apicultural advancement.

To enable the proper upkeep of the stock, Mr. John L. Byard has been appointed Superintendent of the Apiary, beginning September 1. Mr. Byard, besides attending to the bees, will also assist with classes, maintain the apiary building, exhibits, and collections, and prove new methods and implements. The addition of Mr. Byard to

the corps in Massachusetts interested in the promotion of beekeeping should afford further service to eastern beekeepers, heretofore impossible to render.

Mr. Byard is known to the majority of Massachusetts beekeepers through his extensive service as Deputy Apiary Inspector since 1911; as President for three years of the Worcester County Beekeepers' Association, and through numerous demonstrations at conventions and institutes. He is now president of the State Beekeepers' Association of Massachusetts, a delegate body representing the local organizations of the State. His life-long experience with bees began in Vermont with his father, a beekeeper and bee-hunter, since which time he has been in the front rank of practical beekeepers.

Since 1888 he has been recognized as an experienced and successful apiarist in Southboro, Mass. Many a beekeeper in New England will acknowledge indebtedness to Mr. Byard for enthusiasm, encouragement, and assistance rendered them, either as a beginning beekeeper or one confronted with perplexing problems.

DROUTH BROKEN; SHIPPING COMB HONEY; THE IMPORTANCE OF MOVING IT EARLY.

THE drouth that prevailed in many sections of the country has been broken by copious and refreshing rains. Where clover was only partially killed out, the plant will take a new lease of life, for it has wonderfully recuperative power. If conditions from now on are favorable, followed by plenty of snow, there is no reason why clover should not do as well next year as this.

Our Honey Column will give the trend of prices; and it should be borne in mind that now is the time to sell honey, especially that in the comb. If comb honey is not moved by car before freezing weather, it is pretty sure to be broken in transit, and, worst of all, it will begin to granulate. When granulation once sets in, the process is rapid; and of all things, granulated comb honey is difficult to sell.

Comb honey, especially alfalfa, from now on should be kept in a warm room or building. It is very, very important that there be no rapid variation from high to low temperature. Comb honey stored in a room without artificial heat, in the Northern States, may be warmed up by sunshine, and at night the temperature may go down to 60, 50, or even 40 degrees. If the room is, we will say, 75 during the middle hours of the day, and goes down to 50 at night, and if that variation continues for a couple of weeks, granulation is almost sure to set in.

We can not emphasize too strongly the importance of moving comb honey in car lots before freezing weather sets in. There have been more jangles and more trouble over late shipments of comb honey than over almost any other proposition connected with the honey business. Comb honey, when near or below freezing-point, breaks very easily, and a car of it at such times is quite sure to arrive in poor condition.

BRIEF NOTES ON MODERN RATIONAL BEE CULTURE; DEVELOPING AND IMPROVING ITALIANS IN THEIR NATIVE COUNTRY.

The above is the title of a new bee-book in Italian, by Gino Travaini, a teacher in the Provincial Agricultural School of Goritz, Austria. Mr. Travaini has put out a charming and interesting book. But the feature that makes it most interesting to us in this country is the fact that it has so much to do with American hives and methods. While the illustrations and descriptions of European hives and equipments are given due prominence, it is evident that the author has become permeated with the American way of doing things.

We believe it is the general consensus of most beekeepers of the world that the Italian is the best all-around strain of bees. Some of the old original imported Italian queens of some twenty years ago were some of the finest that we have ever seen—not in point of markings and bright golden bands, but in honey-gathering qualities, longevity, and gentleness. If this book shall result in the development of this strain of bees right in its own native clime, it will have well served its purpose in Italy and the outside world at large. At the present time we are unable to secure as fine a strain of imported Italians as we did some years ago. Why this is so, we do not know. If it is because beekeeping has retrograded in Italy, this work will serve to stir up a new interest. It will also mean the development of that strain of bees that has become famous the world over. Speed the day.

MORE ABOUT THE SMOKE METHOD OF INTRODUCING.

For a couple of issues back we have mentioned the success we have had in introducing virgin and laying queens, some of the latter too old to be introduced by any method except the use of smoke. We have been watching Mr. Marchant introducing by this method; and when we asked him if there was not danger of introducing queens by that method he replied, "Not as I do it." His plan is this:

He approaches a hive with a virgin or

laying queen. He then starts the smoker going, giving a dozen or two strong puffs out in the air. When the smoke rolls out of the smoker into the air dense and heavy he blows three strong puffs in at the entrance and then closes the hive. After an interval of perhaps ten or fifteen seconds he picks up his virgin and pushes her in at the entrance. He then follows her up with one more strong puff of smoke, and closes the entrance. In all he gives only four puffs—all that a large smoker will give when the bellows is closed clear down at each puff. Certainly this amount of smoke would do no harm to either bees or queen.

Up to this point Mr. Marchant follows the plan as laid down by Mr. Arthur C. Miller, p. 370, *GLEANINGS*; but instead of waiting 12 hours or over night, he removes the plug over the entrance in some five or six minutes, as he finds it not necessary to keep the hive shut up any longer.

Another thing he discovers is that this way of introducing can not be employed successfully in a small nucleus in full-sized hives, even if the rest of the space be filled up with empty combs. An ordinary division-board placed next to two or three frames is not sufficient to confine the smoke or the queen when she is allowed to run in. There must be a tight-fitting division-board or the queen will run wild into the vacant space; and when she does get back where the bees are, there is "trouble."

In one place where we watched Mr. Marchant he smoked in 23 virgin queens in as many different hives. Of these, 22 were found accepted and laying a few days afterward.

Mr. Miller's improvement over the old Alley plan of using tobacco smoke for introducing is in showing that tobacco is not necessary, and that an excessive amount of any smoke is not only not needed but cruel.

LAYING WORKERS AND A LAYING QUEEN IN THE HIVE AT THE SAME TIME.

For over ten days we have had laying workers and a laying queen in the same colony at the same time, the laying workers pursuing their careless go-as-you-please way, and the queen her careful methodical way. While this has been reported before, the facts in this case may be interesting.

By an oversight a queen that had been introduced to a colony without young brood, some time in June, was not checked up later on, as is our usual custom, and it so happened that the queen was not accepted. At any rate, the colony was left hopelessly queenless for some weeks, and laying workers developed. The true state of affairs

was discovered about the 15th of August. On the 21st, as an experiment, a laying queen was run into the entrance of this colony by the "smoke" method, and, contrary to what might be expected, was accepted and at once began laying. We have known of other instances like this, so that, up to this time, our story reveals nothing out of the ordinary. However, contrary to the usual rule, the laying workers did *not* disappear. Their haphazard work, consisting of several eggs in one cell, eggs attached to the sides of the cells, and eggs everywhere, in fact, continued right along, and yet in the midst of it all could be seen the work of the laying queen. She proved to be a good layer, as her work could be distinguished by the regularity and uniformity—that is, the eggs were in regular order, and always placed in the same way in the bottom of the cells. All about could be seen the work of the laying workers, the appearances going to show that they apparently entered into competition with the queen. It is not often that one can witness in a single comb such a curious combination of the regular and irregular placing of eggs, bordering upon (shall we say?) a mixture of the sublime and the ridiculous. Patches of perfect worker brood could be seen surrounded by scattered drone brood, cells containing larvae and eggs both, others with five or six eggs, etc. How long this struggle between the normal and the abnormal would have kept up we do not know; for on September 1, fearing that the abnormal might prove the stronger we called off the game, removing the laying queen, and placed her in a hive where she would have full sway.

Was this queen an unusually courageous one, or one who disliked to show her authority? The colony being so long without a good laying queen was made up of old bees, most of which were black and shiny. Had conditions gotten so bad that they had given up all hope? or had the laying workers become so numerous that there had not yet been time in the ten days that had elapsed since the queen had been introduced for their work to come to a stop?

AN AMERICAN BEEKEEPER IN NORWAY.

We were recently favored by a visit from a native of Norway, Mr. Ewald Omdahl, Drammen, Norway, who is nevertheless an American beekeeper in every sense of the word, for he uses American hives and fixtures, and he is a close student of American methods. Among writers in this country he is a great admirer of Dr. C. C. Miller and the late E. W. Alexander.

Mr. Omdahl's chief business is the manufacture of leather; but he has a beautifully

kept apiary, managed according to the very latest and best accepted practices of America, right in the heart of a city of 30,000 inhabitants. The bees are obliged to fly a considerable distance. During his three trips to this country he has made a special study of American methods, and has visited various noted beekeepers. His apiary is made up of Carniolans and Italians, not crossed, but in their purity. He prefers the Carniolans, because they work better in all kinds of weather, and are easier to handle.

We doubt whether there is a bee-cellar in the United States with such elaborate means for controlling the ventilation and temperature as this one of Mr. Omdahl's. It is built especially for wintering bees, of concrete, and the temperature is accurately maintained throughout all variations of all outside temperature by means of electric heaters, which can be turned on or off at will. These heaters do not exhaust the air, nor do they give off any bad odor.

This cellar has been used three years without any loss of colonies. Drammen is located on the sea coast, hence is not subject to any violent changes of weather. In many ways the climate is like that of Northern Ohio, as bees are generally removed from the cellar the latter part of March to get the early pollen which comes in the fore part of April.

Among the sources of honey may be mentioned the dandelion, willow, maple, fruit-blossoms, alsike clover (two crops), raspberry, some white clover and basswood, much heather in some localities, sunflowers, blueberry, etc. Two honey-flows are secured from the alsike—one beginning about June 20, and the other in August, but this latter crop is not so sure. The wild raspberry blossoms more or less all summer long. The principal sources of surplus honey are the alsike clover, the raspberry, and the heather. A peculiarity of the heather honey, as is well known, is that it is so thick that it must be extracted before it is sealed over, else it can not be taken from the combs at all in the ordinary centrifugal honey-extractor. From one five-story colony of pure Carniolans, whose queen was imported from Carniola (Austria) the year before, he took \$32.00 worth of comb and extracted honey.

Mr. Omdahl feeds 25 lbs. of sugar syrup, made of two parts of granulated sugar and one of water, to every colony in the fall—generally the first week in September. This amount is fed rapidly and at one time. The sugar is the unbleached yellow granulated sugar, 98 per cent pure, which is obtained from the condensed-milk factories. It is probably imported from the West Indies.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

FOR the second time in my life I have seen a queen sting a worker to death. Aug. 15 I put a virgin not a day old on a comb of a nucleus. The first thing it did was to elinch a worker, which showed it had been stung when it was released, but it did not die till some minutes later. Why did the queen sting that worker? A general spirit of destructiveness is shown another way in a young virgin. After she emerges from her cell in a nursery it is a frequent thing to find she has dug a hole in the side of the cell, as if she would kill the inmate.

THERE you go again, Mr. Editor, p. 561, telling us the average Ontario crop is 63 lbs. per colony, without saying whether comb or extracted. *You* may know what kind, but not every one else does. [There are times when we can not be specific in regard to comb and extracted honey. The reports sent out by the Ontario Beekeepers' Association did not say whether the 63 lbs. average was comb or extracted. The beekeepers of the country very seldom specify the number of pounds of comb or extracted honey. We should judge that most of the honey produced in Canada is extracted—possibly three-fourths of it.—ED.]

P. C. CHADWICK, you're wise to return to the book-record system, p. 600. You can lie on a lounge at home with your book, and lay out a program for the day's work in an out-apiary, saving time and avoiding blunders. Or, if you're too busy for that, you can do your planning on the way out. Then, too, it often happens that one wants to know exactly how something was 5, 10, or 20 years ago, when memory would be hazy about it. I believe the time is coming when every forward-looking beekeeper will count the improvement of his stock a point of the highest importance; and I don't quite see how much can be done in that line without an exact record.

J. E. CRANE, why didn't you ask that question before about having trouble with young queens hatching if a colony was left ten days, p. 564? I had the answer all ready a year ago, and it was this: "For at least 40 years I've followed the rule that a queen-cell could not be started and a queen hatched from it inside of ten days, and I never knew it to fail. I've tried it hundreds—yes, thousands—of times, with never an exception. When I give a comb of eggs and young larvæ to a queenless colony to have cells started, I know I'm safe if I cut the cells in ten days. No, friend Crane, that's one of the things I know, and know

for certain, that with me there is no exception to that rule." But I can't use that answer now. This summer I went to cut a batch of cells ten days after giving the comb, and found the oldest virgin already out and beginning the slaughter of her baby sisters in their cradles. So my answer now must be, "Never? well, hardly ever."

"It is probable that there is no great amount of nectar at any one time in the sweet-clover blossoms," p. 557. Is that the testimony of those who have sweet clover in large quantity? I had always supposed it an abundant yielder, from the fact that the bees are found in such numbers upon it.

P. S.—Just been out watching bees on sweet clover. Besides being thick on it, they seemed to spend at least as much time on each blossom as they do on white clover. [Perhaps the statement in question was a little too strong. There are times and places when sweet clover does yield considerable nectar; but in most localities in the East it does not yield a large amount of surplus, for the simple reason that the plants are scattered in long rows along railways and common roads. It is seldom found in solid compact masses or areas. As the agricultural press is now beginning to wake up to the value of this plant the probabilities are that sweet clover will be very much more in evidence in the future than it has been in the past.—ED.]

A. I. ROOT, old friend, aren't you a wee bit off in thinking that just because that beautiful first Psalm is so brightly hopeful it must have been written when David was comparatively young, p. 585? When he was old, and yet had never seen the righteous forsaken, hadn't he a more substantial foundation on which to base his hopefulness? Besides, look at yourself. Are you any less hopeful as years increase? I'm sure it isn't so "in this locality." [Thank you, dear old friend, for your kindly suggestions. Yes, I do think that as we grow older we should grow more hopeful. The hope of a mature Christian, however, is a little different from that of boyhood; and I still think, but perhaps I can not explain why, David wrote that first Psalm when he was young—say before he got into Satan's toils and had deliberately broken two if not more of God's holy commands. I am glad to know, old friend, that your faith in God's promises grows stronger and stronger as the years pile up. May God grant that the same may be true with each and all of the old "scarred veterans."—A. I. R.]

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

A few days ago the Crop Committee of the Ontario Beekeepers' Association met in Ontario to consider the buckwheat-honey situation. Reports received indicated about the same yield as last year, which means a rather light crop, for last season was a long way below the average. In our locality the yield is much lighter than last year. Rain did not come in time to help the buckwheat; although we have had a light yield of this honey, for some reason the bees stored more honey in the brood-nest than usual, so of course we have the comfort of knowing that the feeding-bill will be lighter, even if the surplus is smaller than was anticipated earlier in the season. Any way, the crop from clover was good, so naturally we do not feel like grumbling at the situation.

* * *

Since writing my last notes for this department nearly all parts of Ontario have had copious rains, and the long drouth prevalent in many places has been broken. Rains came too late in many localities (our own section among them) to be of much help to the clover. As a result the prospect in these places is poor indeed for alike next season. Beekeepers in Brant Co. report good catches of clover, and I understand that adjoining counties in that part of Ontario have been blessed with early rains too; so some parts of the Province will have a good chance of a crop next year any way. It is too early to make a forecast; and, after all, so much depends on weather conditions at the time of the honey season, no one ever knows what may happen, even if prospects are very poor. At the apiary 100 miles north, forest fires got uncomfortably near the bees; but rain came in time to prevent the fires spreading to the apiary. Nothing gives one a more uncomfortable feeling than to fear the results of a threatening fire; and I certainly heaved a sigh of relief when word came that rain had at last stopped the fires from spreading.

* * *

This spring a young man living near me sent to one of our well-known queen-breeders across the line for 25 one-pound packages of bees. The bees were sent just at the opening of the clover flow, and on coming to Toronto were stupidly held by the customs officials or express handlers (perhaps both were to blame) for 48 hours after their arrival in that city. Naturally the bees were in none too good shape when they arrived; but a strange feature of the case to me was that eight queens were dead in the

case, although the majority of the bees were still alive but about starved out. My own experience has always been that the queen will be about the last one to die in case of starvation in hives or cages, and I could not understand the cause of so many queens being killed. My own conclusion at the time was that the queens had been killed when introduced to the bees in the cages; but I could hardly believe that such a thing would happen in case of queens mailed by an experienced queen-breeder. It is only fair to state that the queen-breeder in question acted very fairly and generously in the matter, and these criticisms are not made in a carping spirit. The breeder in question is and has always been noted for his desire to give the "square deal." Perhaps some others who may have had experience in shipping packages of bees may be able to explain why the fatalities among the queens were so high, and whether it is a common experience to find dead queens among the bees when they are shipped in this way.

* * *

NO OBJECTION TO HAVING COLONIES STRONG OUT OF SEASON.

G. M. Doolittle's reasoning on page 442, where he champions the plan of using dummies in the brood-nest for the purpose of forcing all white honey into sections is hardly clear to me. He says that in apiaries of blacks or hybrids the use of dummies will save from \$150 to \$200 in an apiary of 100 colonies; but with a good strain of Italians that will reduce brood-rearing as the flow increases, the use of these dummies for the purpose of repressing out-of-season productiveness is not so apparent. With a non-restricted brood-nest with such a strain as he describes what will happen in the honey season? It has been my experience that it invariably means that the colony will put a great lot of white honey in the brood-nest instead of in the sections; and for my part I should prefer to have the queen occupying the frames with brood instead of having the combs filled with honey. Where there is a buckwheat flow following the clover and basswood, I do not believe there is wisdom in trying to force a queen to occupy as few as five frames with brood, as in such locations there are no periods of from 35 to 50 days between flows as he specifies; but, on the contrary, when there is a basswood flow it makes us hustle to get it off before buckwheat comes on. For "our locality," "bees always strong" is the only safe rule if best results are to be obtained, and I never fret about bees being reared out of season.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

Editor Root, page 593, recommends the Burt system of preventing swarming, as illustrated on page 610. The Burt system may be all right at times; but with our cool nights in California it is a very difficult matter to preserve heat sufficient to get the outside rows of sections completed at best, and any additional air-admitting space should be avoided. This is only in keeping with what I have been preaching for a long time, that plenty of room will retard swarming by keeping the colony cool; and to my notion it is better than the Burt plan. By his plan the bees are simply forced to remain at home to help keep the brood warm by sheer force of numbers, while a hive might be manipulated in a manner that would permit many of the hive force to enter the field rather than to remain to hover brood. I am not sure but that it would be more profitable to allow swarms than to make a condition that will cause loafing inside of the hive to prevent swarming. The plan has been tried to some extent in this climate, and will reduce swarming as claimed; but in at least one instance I have known where a beekeeper used small rocks to prop up his hives for ventilating purposes when it would have been more appropriate to wrap them in blankets to preserve what heat they were able to make.

* * *

Early in the year I mentioned having questioned a number of members at the State convention concerning the color of alfalfa honey, and that many were of the opinion that the difference in color was due to darker grades becoming mixed with it, also stating that I was of the opinion that the pure alfalfa was white. In the April issue of the *Western Honey Bee*, Mr. Harry K. Hill took issue with me, stating that he gets at least three different shades during the season. In the May issue Mr. L. L. Andrews says of orange honey: "Some seasons it is much whiter than others, and at times much milder. In the June issue I cited the fact that every form of nature follows its law, each form on the line on which it was created, and that it could follow only the line given it, regardless of the opinion of man, and that a plant could not under the laws of nature produce more than one color of nectar. In the July issue Mr. Hill says that his observations were taken at a time and place that left no room for doubt on the matter, and intimated that climatic conditions might have something to do with the variation in color. In the same issue

Mr. Bixby says that he has been "wraslin'" with me for two years trying to convince me that the white-sage honey from the disintegrated granite of the foot-hills is much lighter in color than that from the dove lands. Why not alfalfa also? Then he adds, "These fixed laws of nature all have so many exceptions that they wiggle a little. Locality makes a lot of difference." He also says, "Nectar from cultivated buckwheat is often so light in color during the first few days of the flow as to be readily mistaken for clover honey, except for the rank odor." I presume Mr. Bixby does not take into consideration that the difference in soil has any effect on the color of white clover, as he makes no mention of the fact, and does not qualify his statement with a soil condition; and in this, at least, I believe he has weakened his own argument. In the September issue such able men as Mr. J. W. George claim that alfalfa is not white, while others claim that climatic conditions have an influence. Alfalfa honey may not be white—my strong contention has not been that it was, though I have not fully given up the idea yet—but my main contention is that, if it is not white, it must have a color peculiar to its nature, and that it does not change color with the wind nor the moon nor soil, nor does any other plant. If it does, then my twenty-five years of observation have been set at naught, for that would be entirely at variance with my observations. If there were no fixed color for the nectar of the various honey-plants, the mere name orange, alfalfa, white clover, basswood, etc., would mean nothing so far as color is concerned, as it might range anywhere from white to dark amber from the same source.

It will take a lot of evidence to prove to me that climatic conditions or soil have any influence on the color of nectar, any more than the atmosphere or the color of the food that I eat has any effect on the color of my blood; for, as I have said, it is not consistent with nature; besides, I am not willing to admit that I have no assurance of the color of honey I shall get from the orange alone or sage alone, though these trees and plants are growing on several kinds of soil within reach of my apiary, and there is always a variation in climatic conditions during the honey-flow.

This question is at least worth discussing; but I believe the majority of beekeepers will sustain me on my opinions of this matter.

Beekkeeping Among the Rockies

WESLEY FOSTER, Boulder, Col.

BEEES AND PARCEL POST.

I had two two-pound nuclei shipped April 15 from Texas. These bees were not shipped in the regular packages as shown in April 15th GLEANINGS, but were sent in the two-frame nuclei boxes with one frame and a bottle of water. The queens were caged. The sponges placed in the bottles came out during the trip, but the bees had not apparently suffered. One package weighed 9 lbs. and the other 7½. When started from Texas, three and a half days before, they weighed 18 lbs., according to the express billing.

The cost of shipping these two nuclei, weighing 18 lbs. combined, was \$2.63, or at the rate of 15 cts. a pound. By mail it would not have amounted to more than about five or six cents a pound. And, beemen, there is no reason why we can not take this matter up with the Postmaster General and get bees sent in pound, two-pound, and five-pound packages by parcel post. The Postoffice Department does not put all mail into sacks. The postmaster at Boulder told me that all fragile goods are handled outside of mailsacks just as carefully as is done by the express companies. Eggs are being sent all over the country for setting, and baby chicks are being sent the same way; and I should like to have some one tell me why it would hurt a postal clerk to get stung any more than an express agent. Why can not the Postoffice Department handle this business as well as the express companies? We will see that they can very soon, for we can not have discrimination.

* * *

THE PSYCHOLOGY OF INCREASE.

We have the psychology of business, the psychology of success, the psychology of the mob—nearly every thing is psychological these days, so why not put bees in the psychological category? There is about as much psychology in a hive as in any thing I know of, and Mr. Maeterlinck would probably say there is a great deal more. All of which, by the way, is introductory to what I want to say regarding making increase without lessening the honey crop. Coming back to psychology again, it should be remarked that the Alexander plan of making increase is taking advantage of colony conditions at the psychological moment.

Bees built up with gratifying rapidity last spring. In an apiary of 100 colonies, one-fourth of them had brood in all their ten frames by April 30. Combs of sealed

brood and hatching bees were given to all weak colonies, and many hives with more honey than needed were relieved of some, and empty drawn combs were put in their places. Forty combs of honey were taken out in this way to give room for breeding. This honey went back to the bees again a little later to feed the brood and young bees coming on.

Our main honey-flow does not begin until early June, so that, in order to keep our bees on the up grade, we use the Alexander plan of increase on all we can. The queens must be kept busy laying until June. If we can keep them laying, there will be less swarming, and we will have twice as many workers for the alfalfa harvest in June, July, and August. When we take eight or nine frames of hatching brood and place them over an excluder with the queen below, and an abundance of combs all clean and ready for the laying of eggs, that queen just gets busy, and it keeps her busy for some little time too. In ten days the upper hive with queen-cells, perhaps, may be set aside, the cells cut out, and a young queen given. Feeding may be necessary, but it will pay well to feed both lots of honey if necessary to keep up brood-rearing. A hive jammed full of brood June 1 to 10 is going to begin super work much sooner than one that is half full of brood. The first forty pounds of honey will go below if there is room for it.

The defects in the queens will show up right along when conditions are such that the queens are unhampered for egg-laying room. You will soon realize the need of extra queens. One, two, or three dozen on hand all the time these days will be an advantage.

Educational Apiary in London

In the 1912 Reports of the Zoological Society of London which I have just received I find the following on pages 8 and 9:

BEEKEEPING.

The Council arranged with the British Beekeepers' Association, which had received a grant from the Development Commissioners for the establishment of an experimental and educational apiary in London, to provide accommodation at the Gardens. A site on the north bank of the canal was selected for the apiary, made suitable for hives and for demonstrations, and the use of the lecture-room for lectures was given. The association paid the society a small rental to cover expenses, and agreed to remove the bees if their presence proved injurious to visitors or to the animals. So far as the society is concerned, the arrangement worked satisfactorily in 1912.

Valparaiso, Chile, June 10. J. A. WOLFSOHN.

At Borodino, New York.

GRADING AND CRATING COMB HONEY.

"How shall I crate my comb honey? This is my first experience in sending honey to a distant city."

"I would advise you to put not over twenty sections in a case, and then to put nine of these cases in a crate made with two handles on each side so that two men can handle it. This large crate will weigh about 200 lbs. In this way there is not the liability of breakage that there is where each of the nine cases of twenty sections each is shipped separately. This is on the supposition that you will ship your honey as freight. Comb honey by freight is much less liable to breakage than when sent by express, for all express matter is handled very rapidly on account of the short stops of such trains."

"But my honey is of different shades of colors, some being made from clover and basswood, some from buckwheat, and some from goldenrod and fall flowers."

"These different kinds should all be kept by themselves, and not mixed. You would hardly expect that a man having apples of different kinds to sell would mix greenings, Baldwins, and Spies together, would you?"

"No. But suppose he has those greenings, Baldwins, and Spies, each in different piles, and all of them are nice smooth apples. And we will assume that, as to size, they run from 1½ to 3 inches in diameter, and that some of them grew on the sunny side of the tree, so that they are nicely colored, and some in the shade, with little color on them. Will he pick them up promiscuously and put them in the barrels thus? or will he put the largest and nicest-colored in the bottom and top of the barrel, filling in the center with the remainder?"

"We are now getting at some of the old difficulties of the past. Possibly I can answer better by telling you of the instructions I received from a man to whom I sold apples a few years ago. He bought thousands of barrels of apples, and shipped them to large cities. In the first place, no apple was to go in that would go through a hole bored with a two-inch auger, no matter how smooth, perfect, or highly colored. All these were to go in as seconds. Then from the firsts and seconds the largest and best-colored half bushel was to be selected to go into the bottom of each barrel marked firsts and seconds. These selected apples were to be placed stem down on the bottom of the barrel till that was covered, when the rest of the half-bushel was carefully poured on them. Two bushels were now picked up

promiscuously and put in the barrel. A second half-bushel of apples was selected as was the first, and poured on top. The barrels were now headed up, turned over, and marked firsts and seconds, with the kind; and when shipped the shipping directions were put on this end, so that, when opened at their destination, the row of choicest fruit would stand out prominently, stem end up, which gave a very inviting and tempting appearance."

"But was not such a course a sort of fraud?"

"That was the question I asked, but was told that the market demanded this way of putting up apples; and unless I put them up according to instructions the apples would not be accepted, as the buyer could not get market prices in any of the different cities he shipped to unless they were so put up. I protested a little to draw him out, and was met with 'How can it be considered a fraud to put up apples thus? All apples that will not go through a two-inch hole are called in market firsts or gilt-edged. I do not retail these apples, but sell from one to forty or more barrels to grocers and jobbers, and these men specify how I must put them up.' Now, while this does not fully apply to honey in sections, yet it has a bearing in the matter. First, the different kinds of honey should be kept separate, and such sections as have mixed honey in them should also be kept separate."

"Second, while no two-inch hole can be used for grading honey, yet each kind should be sorted as regards travel-stain, evenness of comb, unsealed cells, etc., generally making three grades, as fancy, firsts, and seconds, doing this grading carefully and honestly. Now, as with the apples, let us suppose the honey is graded, and we are casing fancy. We take out enough sections to fill a case. How are these sections to be put in that case? Haphazard? Not one buyer or commission man has so instructed during my forty odd years of beekeeping. All have believed that it was perfectly right to select from *that case a number of sections* those that are the best, and put them next to the glass. Yea, more. I have always been instructed to turn the best or face side out at that. But you will note that this dishonest facing matter hinges on the sorting or grading rather than on any thing else. For a man to go through his crop of honey and sort out the very best sections, and use these for 'facing' his cases of culls would not only be dishonest, but also very foolish, even from a business standpoint."

General Correspondence

A NEW PLAN FOR THE PRODUCTION OF COMB HONEY AND FOR THE ELIMINATION OF SWARMING

Cutting Extracting-combs in Pieces and Fitting them into Sections for the Bees to Fasten

BY DR. G. A. HUMPERT

Some weeks ago we received a letter from Dr. Geo. A. Humpert, a specialist, of St. Louis, Mo., who had evidently taken up beekeeping for pleasure and profit in his back yard. He said he had developed a new system for the production of comb honey that would make it possible to secure perfect sections of honey, all fancy and No. 1, with no seconds; and, more remarkable still, he would be able to eliminate the nuisance of swarming. He desired to know what we would pay for such an article, saying he thought it ought to be worth a considerable sum; for if one could produce all fancy and No. 1 comb honey and eliminate swarming, it would mean a good deal to the fraternity. We were not willing to pay any definite figure until we could have some knowledge of its feasibility from some disinterested party like Dr. C. C. Miller, of Marengo, Ill. The result of our negotiation was that the plan was to be submitted to Dr. Miller in all its details, and that Dr. Miller, after examining the same, should give us his unbiased opinion of its feasibility without revealing the method or any detail thereof.

This was done. After examining the system carefully the doctor wrote us that he did not believe it would prevent swarming, but, of course, did not explain why. Later he was given permission to do so, and then wrote us that the system would fail in swarm prevention because it did not provide *drawn* combs, such as the extracted-honey man gives his bees; that in the matter of fitting the filled combs into sections and letting the bees fill them, he did not know, but had some doubts.

This letter of Dr. Miller satisfied us that we could not pay very much for the method. Further negotiations resulted in our securing the privilege of examining into it ourselves with the privilege of placing it before our readers.

We would not go so far at this time as to say there may not be some possibilities in the plan. It will pay every one of our readers to go over it carefully, for it is not only exceedingly interesting but it suggests a train of possibilities that may be worth developing. Here is the article:

Once upon a time a patient said to me, "Doctor. I owe you a little bill. I haven't the money to pay you, nor do I know when I shall have any. If you could use a stand of bees I might accommodate you."

It has always been my policy to take whatever I can get. So I took the stand of bees. It was an old-fashioned box hive. The man said that he had always intended to transfer them to a patent hive; but—he was afraid. In fact, he had been afraid to rob the bees. The hive was a sectional affair, about five feet high, and his wife explained that for two or three years preceding she had always urged "Henry" that the bees needed room. Then Henry would make another section, slap it on, and—run.

I had always been vaguely interested in bees, credited them with almost supernatu-

ral instinct, yet knew but very little about them; but now the interest became acute. I hastened to the public library and secured what books I could find on the subject. I also subscribed to the various periodicals on bee culture, and, as a natural sequence, was soon in the toils of the supply manufacturers. After the most careful consideration and judicious selection a beginner's outfit was ordered. I remember with what feverish impatience I awaited its arrival. Several tracers were sent after the shipment (unnecessarily, I have no doubt). When it finally arrived I went to work and transferred the bees *secundum artem*. Dear me! what a mess it was! hundreds of the poor little workers succumbed to my inexperienced brutality—the more brutal because of my own fear and trepidation. That her royal highness did not perish was a wonder. However, in a crude way I succeeded, thanks to the industrious workers, in repairing the damage I had wrought.

The bees did well; in fact, I raised more bees than honey, so that by the following year I had six thrifty colonies on the rear part of a town lot, and began to resent the term "beginners" so often met with in the books and journals, as applying to me. My neighbors began to complain; but being now thoroughly inoculated I concluded to remove to a country town. I chose to ship my goods on a boat up the Illinois River, thinking that it would be easier on the bees; but when I followed the last load down the levee I was met by the drayman who asked what he was to do with the bees, for the captain wouldn't receive them. In surprise I inquired why. "I don't know," said the drayman; "he simply swore, and, I believe, is swearing yet; but I got one hive on all right before he stopped me."

I went on board, hunted up the captain, and, when I asked why he would not take the bees, he replied with a string of oaths which, in the way of emphasis and vehemence, I have no doubt was quite artistic, but did not answer my question. In an effort to conciliate him I gave every assurance that the bees were well packed, and could inconvenience no one. Then the captain made some very pertinent remarks:

"Yes," said he, "that's what the beekeeper also declared who shipped bees on this boat several weeks ago. Well packed! yes, may be they were; but when a roustabout knocked a hive off the stack it smashed. The whole air was filled with angry bees, and every d—d nigger jumped into the river. We shoveled the busted hive into the

river, but the bees stayed on board looking for it, or the niggers—I don't know which. The upshot was that we had to tie up there for nearly a week until the bees quit bothering before the niggers would venture on board again to work the freight. No, thank you; bees don't go on this boat again, even if you paid double freight."

It was useless to argue. I was obliged to sell the unshipped colonies at a loss.

One colony, however, came through all right. That, in the course of time, increased to some thirty; but my new locality, though affording more elbow-room, was really a poor one for honey.

Some three or four years ago, when feeding back a lot of scraps in a super, I observed, after a time, when every brood-frame was doubtless filled, that the bees no longer took the honey down, but, instead, fastened the scraps to each other and to the vessel in which I had placed them. This gave me an idea. Instead of compelling the bees to build in the small sections, toward which they seem to have a natural antipathy, why not permit them to do the principal work in the extracting-frames, then cut it out in suitable plugs, or squares, insert into the sections, and put them back on surcharged hives to fasten up?

With feverish haste I selected a few well-filled extracting-frames, and, in a crude way, cut out a number of plugs just the size of my sections, slipped them in, and set the sections over the same hive. The following day I took them off, and, lo and behold! they were all firmly fastened. It is true that the job was not a neat one. Some had toppled over, owing to the fact that the lower cut had not been exactly at right angles with the surface; others,* for the same reason, were fastened in rather crooked; but they were all nicely fastened. Moreover, wherever the sections had been smeared with honey they were licked dry, and not a speck of propolis was to be seen; they hadn't had time to daub them up.

I figured that it would be cheaper to put in full sheets of thin foundation in shallow extracting-frames, just the size to yield four sections; and that with special knives rigged up in such a way as to cut out the plugs accurately with one stroke, slipping in the plugs, putting on and taking off would be preferable to putting foundation into the sections separately and scraping off the nasty propolis. Moreover, every section would be filled—no half-filled sections, some with merely a dab of honey. Last, but not least, the well-known preference with which bees fill large frames to small sections would insure a larger yield of section honey; furthermore, swarming could

be controlled, even as in the production of extracted honey.

The following winter I devised and constructed a machine consisting of a set of five knives screwed four inches apart upon a common pivot. These knives puncture the comb just beneath the top-bar, when a gentle pressure on a foot lever forces the blades through the comb to the bottom-bar. The comb is next slipped back off of the knives before the foot releases the pedal. This completes at one stroke the five vertical cuts. The machine is made large enough to hold a superful of combs, and to fit snugly on a tin pan which catches all of the honey drip. The horizontal cut is made by a pair of knives mounted in one handle four inches apart. For this purpose the comb is laid upon an inclined plane, whence the honey may flow into any vessel, and where the sections may be slipped over the plugs of comb after being slightly separated, allowing space for thickness of the sections.

Being ready for business I impatiently awaited the next honey-flow; but the following year proved an absolute failure in my locality. Then, very much like a grazing horse that always thinks the grass in the distance is better than that near by, I moved again. This time I chose the northwestern portion of Missouri, when, lo and behold! the drouth there the following year (1911) was so severe that the bees had a struggle to maintain themselves. Completely discouraged I turned my attention to professional matters, and left my pets in the care of inexperienced hands. The consequence was that many of them went into winter quarters with insufficient stores.

With the following spring my interest reawakened; and hoping that I might try my experiment on a larger scale I again looked after my bees personally; but, alas! over half had perished, and the remainder were too weak to make a fair test. Any way, the spring of 1912 was little better in that locality than 1911. However, the fall flow was some better, and I found it possible to make the test. My first difficulties were in finding but few of the extracting-combs, which I intended to cut into sections, as perfect as I desired. Owing to the inexperienced help, many of those frames (filled with full sheets of thin foundation) had been on the hives too long during the two failing springs preceding, consequently some had been but partially built out, while others had been gnawed and disfigured. The imperfect combs did not prove to be as much bother or loss as an equal number of imperfect sections would have been, for they were all extracted, though the first ex-

tracing had to be performed with care on account of the thin foundation.

After selecting the best combs, my son and I went to work. The first step was to slide the comb so the five knives simultaneously penetrated it just beneath the top-bar, then a downward pressure of the foot on the pedal forced the knives through to the bottom-bar, completing the vertical section. Then, slipping the comb back, it was laid upon an inclined slab (which drained into the uncapping-can). Now the two knives mounted four inches apart in one handle were inserted and the longitudinal cut made. This double operation was made in less time than it takes to describe it. But the following steps were a little more tedious. The plugs had to be slightly separated to permit room for the thickness of the sections. However, the plugs fitted exactly; but I discovered that, if the slab were hinged in such a way that it could be raised into a vertical position, thus facilitating taking off the filled sections without fear of having the plugs slip out, it would be quite an advantage. Yet I worried along very nicely. In placing the sections in the supers I tried to overcome another difficulty; it has been my experience (and, I believe, every bee-keeper's) that bees will wax up or propolize any contiguous parts; but where there is bee space it will take some time before they will get to daubing. Here's where I spent a lot of useless time. At first I had driven nails through slats to rest in the bottom of the supers with the points projecting upward about $\frac{3}{8}$ inch, intending to set each section on four nail-points, and as far apart. (I had a number of large supers, made to fit the Dadant hive, otherwise this would not have been possible). Thus I expected that, if there were any daubing at all, it would be only at the nail-points; however, this was a failure. Too much time was wasted in placing the sections, and the care required in handling to prevent toppling over. Then I resorted to a modification of the old T tins; but instead of being shaped thus  I enlarged the center fold thus  so the requisite bee-space was secured, and the sections could be quickly placed.

Now, in my impatience I chose six of my strongest colonies and put two supers on each to be sealed. In twenty-four hours I removed them. Yes, they were all fastened: a few plugs had toppled over, but, alas! many cells had been emptied. I had neglected to gorge those colonies first, thinking that, as they were the most populous and wealthiest of all, they required no preliminary treatment. Somewhat discouraged—yet determined to hold out—I proceeded to

gorge three colonies and tried again with better success; and, being also more careful about the longitudinal cut, so as to get it square, and at right angles with the surface, none toppled over. Ah, the beauty of it! though the sections had been daubed with honey they were all licked clean, and not a speck of propolis. Only one doubt remained—were those plugs sealed as firmly to the wood as otherwise? Apparently, yes; but after a little rough handling at the store two dropped out. Hereupon I left them on 36 hours instead of 24, with better results.

Such were my results, but what avail? Most of my bees had perished; and, considering the uncertainty of season and locality, I chose to devote my whole time again to my profession. My son also, who, I hoped, would become a successful apiarist, determined instead to become a machinist. To perfect himself in this his ambition turned to the metropolis, where opportunities and facilities existed. Having but one son I dreaded an early separation, so I completed the circuit and moved back to St. Louis.

Not being in position to test this method of comb-honey production any further I give it to the public for what it is worth. I am convinced, however, that any one in a fair locality would soon become proficient with this method. Practically the bees would be treated the same as in the production of extracted honey, with the exception of the hives utilized for fastening and finishing up. Yet with those, though being gorged, could be given plenty of super room and thus discourage swarming. Some more experience is necessary to ascertain just how long the finishing process should last to secure best results. I had as many as six supers at once on the strongest colonies. It seemed that better results were secured with four or six supers than only one. The more dripping honey there was to be cleaned up, the less space they had left to put it. As to the fastening up, it really seems to be instinctive. The bees themselves appear to dread any loose combs or parts.

St. Louis.

[Before negotiations had been completed by which we were to publish the article, and after securing Dr. Miller's opinion, we in turn wrote our own "opinion," a part of which is given herewith:

Mr. Geo. A. Humpert:—Your favor of July 12, with the enclosure of article describing your system of comb-honey production and swarm prevention, together with letter from Dr. Miller, was duly received. We don't wonder that it seems fascinating to you; and unless one has had a very large and extensive experience, and opportunity for extended observation, he might be misled, just as you were in part.

We have been over Dr. Miller's letter that he has written to you, and would endorse every thing he says, especially where he says your plan would not prevent swarming. Your scheme is based on the idea that, when running for the production of extracted honey, there would be little or no swarming. This is correct when the hives are properly managed—that is, providing that empty drawn combs are given the bees fast enough, or, rather, often enough, so that at no time are they ever crowded for room. But your plan does not contemplate the scheme of giving extra room. You produce your honey in the first place in shallow frames. This honey must be built off from thin super foundation, and in that respect you are no better off than if the combs were drawn out and filled with honey in sections. Now, this may be a new fact to you; but we have been producing comb honey in shallow supers for the last six or seven years. We are mailing you under separate cover a sample of our cut comb honey, such as we have been supplying to the Pullman-car trade during that period.

Naturally enough, we supposed, as did you, that when we produce extracted honey in shallow frames we would reduce swarming; but in this we were very greatly disappointed; in fact, we can see very little difference between the behavior of colonies drawing out foundation in shallow frames and colonies drawing out foundation in sections. The one seems to be almost as bad as the other in respect to swarming. But, on the other hand, if we can give shallow extracting-combs, *already drawn out*, mind you, there will be little or no trouble from swarming, providing these supers are put on often enough to give the bees room as fast as they fill one set of combs. The theory of swarm prevention in extracted honey production is empty combs all ready for the bees. On that point Dr. Miller is exactly right. The thing that makes bees start to swarm is building combs, simply for the evident reason that they have not any store room ahead. When that condition arises, and the hive is a little crowded, swarming is almost sure to be the result. Bees seem to be disinclined to build comb, and they will swarm before they will do very much of it—that is, unless other preventive measures are employed.

In your letter to us, however, you say that the matter of swarm prevention is not your only idea. We can readily see that. It involves the old scheme of producing comb honey by a plan which you believe will give perfect combs, free from soiling, by making the bees attach those combs to sections after they have been drawn out and capped over.

Right on this point it is our belief that you would not be able to get the bees to attach these combs to the sections as firmly as if they had been built there in the first place. The very fact that some of the combs dropped out in shipping is rather an indication of what might happen if a few cases of comb honey produced in this way were shipped long distances as ordinary comb honey has to go.

Now, we have spoken rather frankly, and in a way that almost indicates that your invention is of no value. So far from believing that, the fact that we have been using something along similar lines would indicate that we do attach some value to cut combs, not on the plan that you employ, but on the plan that we use in putting them into cartons and then wrapping up afterward. Combs will ship in cartons very much better than they will in sections. You see we have a saving over you in that the bees do not have to attach the combs to any thing. We simply cut them up and then put them into cartons and wrap them up.

Taking it all in all, we think you will see that the plan we have been working upon is an improvement on yours in that the combs do not have to go back into the hives to be attached to the sections. We simply produce shallow extracted honey, cut it up afterward, and then wrap it up as shown in the

article in GLEANINGS for Dec. 15, 1909. This plan has the advantage over the one that you mention in the fact that comb honey can be shipped in this way around the world, because it is not attached to any thing. The difficulty with ordinary comb honey in sections is that the combs break away from the rigid support of the section. That is the reason why the comb-honey business has been going to the bad, and nearly every one is working toward the production of extracted honey. E. R. Root.

As stated in this letter, we have had a great deal of experience in cutting up extracting-combs into small squares or plugs for the Pullman-car trade. This plan was illustrated and described in our issue for Dec. 15, 1909, as already stated. Since that time we have continued the business of comb-honey production, but not on the regulation lines. We found a considerable demand for these cut combs, especially for fancy restaurant and dining-car trade. We have not attempted to cut comb honey in squares weighing a pound or more, but have only catered to the trade that calls for individual service of comb honey—that is, little chunks weighing between two and three ounces. Well, having been at this business for the last seven years, the scheme of producing comb honey in shallow extracting-frames was a rather old one to us. We have not, however, tried the plan of cutting the combs of just such a size as to fit neatly the common section honey-box. Without having tested it, it would be our opinion that these combs would not be as stable in the sections as those built there in the first place; that the cut comb afterward fastened in the section would have a sort of stuck-in look—that is to say, it would not have the finished appearance of a nicely built comb that has been built in the sections from foundation. However, we are open to conviction; and if Dr. Humpert has struck upon a new and simpler plan of producing section comb honey we feel sure that the beekeeping world will be glad to pay him for it. While he may be able to secure a patent on the appliances for cutting the combs, he could not very well protect himself on a patent covering the method of letting the bees fasten the cut combs into sections. Honest beekeepers, of course, would pay the doctor a royalty; but thousands of dishonest ones, and others who might claim the idea was old, would disregard his rights, secure in the belief that he would never know that they were purloining his invention.—ED.]

Comb Honey, 214 Lbs. from One Colony

This has been a fine season. I have taken 440 lbs. of comb honey from five colonies, my best giving 214. I think that is good for one in the A B C class. Springfield, Ill., Sept. 2. A. C. BAXTER, M. D.

A COLONY OR TWO OF BEES

How They May Reduce the Cost of Living

BY W. R. COMINGS

[The writer of the following article, Mr. W. R. Comings, superintendent of the public schools of our neighboring city of Elyria, a place of 15,000 inhabitants, deserves more than passing notice. Mr. Comings was formerly superintendent of our own Medina schools, and during that period, in the late 70's and early 80's he had much to do in shaping the future policies of a number of the boys, particularly of ourself. It is not too much to say here that we feel more indebted to him for our educational training than any other teacher we ever had. Always up to date, he is most of the time a little ahead of the world. His schools in Elyria show that in every room. Well, when he took up beekeeping, it was presumed, of course, that he would use modern methods at the start, and he did. Not only that, but his progressive mind has been looking toward new and old fields. He writes:—Ed.]

Why do I keep bees? First of all, for the fun of it. Second, to reduce the cost of high living, or, rather, to have a taste of high living without any cost.

Formerly the annual purchase of honey for the family was not above half a dozen pounds a year. Honey was a luxury, and rather expensive, as I fancy it is to a great many people. But if bees would pay their own way, why not have honey in plenty? And then I had a little sportive desire to see what I could do with bees, and so last year a colony was ordered of my good friend Root.

The interest I have taken in those bees has amply repaid me, for all along it is a bit of nature study with an incentive. But I have nothing new to add to the beekeeper's lore. I have an argument to present. But first let me remark that there were many dark forebodings about those bees. The good wife had visions of their flying straight into the faces of all the neighbors and the neighbors' children, and there are no less than six families living within sixty feet of that miniature apiary. But no one has been stung besides myself, and one is soon immune to the poison-punctures.

Well, that colony doubled the first season and produced sixty pounds of delicious sweetness. This year the two colonies increased to four, and the season's crop was 285 pounds. Enough honey has been sold to eliminate all costs, and there is honey on the table every day. Hereafter my honey costs me nothing.

Are not these facts sufficient justification for my preachment, which is that every householder should keep a colony or two of bees. They make little work, occupy almost no space, turn out a good product, reduce the cost of high living, eliminate largely the craving for expensive sweets and chocolates,

and provide a diversion for the tired man after business hours or on holidays.

The next step might be a goat or two if one cared to go that far; but I stop with the bees, and shall continue to buy milk as long as possible.

Elyria, Ohio.

SHIPPING FULL COLONIES 1000 MILES BY EXPRESS

BY M. A. PETERS

While living at Spring Valley, Ohio, in the spring of 1910, I was the happy possessor of 72 fine colonies of bees that had wintered in fine shape. If I remember rightly, there had been some willow and dandelion bloom. I suddenly decided to move to Ft. McCoy, Fla., and take 42 colonies with me. The problem arose as to how to ship them. The railroads would not accept them by freight, and eight-frame hives partly full of honey were too expensive to go by express. Therefore I resolved to use light shipping-cases $\frac{3}{8}$ x 4 inches wide, and the snug length of a Hoffman top frame bar. The sides were to be made of wire cloth, and tacked every $1\frac{1}{2}$ inches. Those cases were made two inches deeper than the frames. There were cleats nailed inside of both ends high enough to make the frame level with the top.

One frame one-half or two-thirds full of honey and some brood were put in each case, directly in the center. Each colony was carefully shaken into the case; the lid nailed, and two screws put down through into the top-bar of the frame to prevent turning sidewise. About ten of those were nailed into a light skeleton crate ready for immediate shipment by express. Empty hives had been sent on ahead by freight to receive those when they arrived at their destination. The hives containing combs were sent on immediately after.

The bees arrived at their destination not much the worse for their long ride, although it seems to me that it would have been better if they had been provided with a little water, as they seemed very thirsty when turned loose.

Bees properly crated in this manner could be safely shipped 2000 miles. Plenty of sealed honey must be provided for such a trip, as the consumption of honey seems to be considerably above the normal.

I shipped by freight several hundred fine newly drawn combs wired four times across. Those came through with scarcely a break. I put about 100 into a box, and packed them very tightly.

George Zautner and family, of Albany, N. Y. Another view of Mr. Zautner's apiary is shown on the cover of this issue. See editorial.

AN OLD BUT VERY EFFICIENT FRAME-NAILING DEVICE

BY J. L. BYER

While beekeeping has, no doubt, kept pace with other industrial pursuits during a number of years, shown by the many new things that are constantly brought to our notice, yet every once in a while some old device or plan will be found that, after all, is better than the modern methods which are supposed to supersede the more ancient ones. The frame-nailing device illustrated here is in this class; for while my grandfather and his brother used this forty years ago, I have yet to see a better plan, although I have seen a great many other devices for this purpose during the past ten years or so. Indeed, I doubt if there is another one as good as this, all things considered, as frames nailed in this device are absolutely *on the square*, and a good smart operator can nail up quite a few hundred frames in a day, and work in a position that is not tiresome to him.

Figure 1 shows the front of the device. The only movable parts shown in this picture are the lever at the bottom right-hand

corner, and the two pieces about six inches long at the top, marked each with the large crosses. The block inside the four corners designated *a-a* is the exact inside measure of the frame. The foot lever at the bottom is shown raised up, and the holder is ready for the frame in the flat to be placed ready for nailing. The top-bar is laid flat in the space at the bottom of the block marked *a* at each corner, and the end-bars stand upright in the grooves shown at the ends of said block. The bottom-bar is placed in position on top of this block; the foot-lever is pressed down, and the two strips marked with *x* clamp the frame solidly for nailing. The frame is now nailed; and then when the foot lifts the lever at the bottom, the job is done. It takes much more time to describe the process than to do the work, as an active nailer can at least run one a minute.

The two smaller crosses, lower down, show a shelf for nails which is divided into two compartments, one for the small nails and one for the larger ones for the top-bars. The device should be constructed so that the top leans away from the bottom at least eight or ten inches out of perpendicular, and the front should be of inch lumber.

I might add that the block referred to,

FIG. 1.—Front view of Byer's nailing-device.

and marked at each corner *a*, is simply made of a piece of inch lumber the exact size of the inside measurement of the frames to be nailed, and is fastened to the other boards that extend from the bottom upward.

Figure 2 shows the rear of the machine, and I think it is made so clear that little explanation is necessary. The strip from the foot lever up to the two diagonal pieces in the center is made of a heavy piece of band iron. It is fastened at the bottom with a small bolt, and the two pieces above are sawed so that there is an inset to allow the iron strap to enter them about two or three inches. Small bolts fasten them to the iron. At the top, each one of these diagonal pieces is fastened to the pieces shown on other side, marked *xx*, by wooden pins. When the lever is pressed down these pieces move down in the grooves as shown in the left side of Fig. 2, and so firmly lock the frames to be nailed that they can not move while the nailing is going on.

A REMOVABLE PORTICO FOR WINTER PROTECTION.

At different times I have mentioned the name of J. F. Davison, Unionville, Ont., as a beekeeper who believed in a low temperature for cellars in which bees are being wintered. Whether right or wrong, it is quite evident that for *his* cellar it is all right, as

he invariably winters his bees in first-class order. In addition to the bees wintered in the cellar, he also winters about as many outdoors, and the picture shown illustrates the plan he uses to protect the entrances from wind, snow, and also to keep the sun from shining directly in the entrance on days when cold winds are blowing but when the sun is quite warm, enticing the bees out only to perish as fast as they come out. The bottom-boards of the packed hives project about four inches, and the porticos shown rest on the bottom-boards, and project out at the bottom about two inches further than the bottoms of the hives. This allows the bees to carry out their dead; and if by chance the beekeeper is away and a warm day comes, allowing a good flight, the bees can find their way back to the hive. The portico always insures an air-space next to the entrance, no matter how much snow may be piled over the hives; and it is an effectual preventive of cold winds blowing in at the entrance. The sides of the portico rest on the bottom-board of the hive; and on the top a piece of band iron screwed fast to the hive is bent so as to turn down over the portico and hold it in place. The hive marked with a cross shows the "button" turned down in place, while the one at each side of this hive shows the

FIG. 2.—Rear view of Byer's nailing-device.

Apiary of J. F. Davison, Unionville, Ont., showing the removable portico for winter protection.

pieces of iron turned to one side and the portico ready to lift off the hive. These porticos have been used in this apiary for a number of years, and are as good as any thing I have ever seen for the purpose intended.

Note the nearness of buildings—apiary right in the center of a village, which shows careful handling on Mr. Davison's part, as the bees have been there for many years.

Mt. Joy, Ont., Canada.

A FEW WORDS IN DEFENSE OF WINTER AND SUMMER SHEDS

BY L. LIST

The Jan. 15th issue contains a severe criticism, p. 55, of the combined winter and summer shed described by me Dec. 1, page 766. It never entered my mind that the shed described should be the *ne plus ultra* in wintering contrivances. It is, however, quite satisfactory for a busy man who, because of other more pressing duties, can not, like the professional, aim to get from his bees "all there is in 'em." Of course it has a few drawbacks. I do not use this kind of shed myself, as Mr. G. could have noticed by carefully going over my words. I have regular cases for winter (see illustration), and shade-boards for summer. Still, I consider this shed of interest to some of the thousands who read *GLEANINGS*. Mr. Greiner himself, though he utterly con-

demns the whole thing in some sentences, and warns beginners not to adopt it, at several other places offers suggestions how it may be greatly improved.

I still believe that many of our small beekeepers, especially in the country, would do well if they, without much trouble to themselves, would protect their bees according to Mr. Knoll's way. Mr. K. is a prosperous, busy farmer, and only his spare moments can be devoted to bees. Thousands of other beekeepers are in a similar position.

But let us look at a few of Mr. G.'s objections. He considers straw poor packing material. For four successive seasons my bees were packed that way, and during that time but one colony, weakened by disease, was lost. No kind of packing could have saved it. Straw, by the way, comes through the modern thrasher in pretty fine shape—plenty of chaff in it too. And if it were not broken up, wouldn't it then give us innumerable dead-air spaces between the hive-body and the outer wall? Last year's winter was certainly a most trying one. Mr. K.'s bees came out in fine shape. So did mine. Another objection: Hives can not be easily manipulated. True, not so easily as when spread out in the open. But it can be done fairly well. I went through every one several times last summer, removing every frame. I admit that the bees are likely to be stirred up a little more than when they are entirely separate. But Mr. G. himself

Winter cases as used by L. List, Detroit, Mich.

says that one would not notice it very much in the sheltered position behind the shed.

Finally, the suggestion regarding a change in construction to keep out rain and snow is quite superfluous. Rain and snow have no chance to get inside of the shed, though it appears that way in the picture. Let me explain. That photograph was taken in the middle of summer, and the hinged front was simply let down for a few minutes, the hives being left standing apart. For winter they are moved close together. From one long and several short pieces of $\frac{3}{8}$ -inch stuff an entrance is made $\frac{3}{8}$ by 5 inches. Then a narrow board, just wide enough to fill out the space between hive and wall, is laid on top of these entrances lengthwise, inside of the shed. The space above is filled with straw. Last winter we had many a driving snowstorm from the east, the direction in which the sheds are facing. No snow ever got inside.

Detroit, Mich.

A WINTER CASE FOR TWELVE HIVES

BY J. F. ARCHDEKIN

Having sustained serious winter losses in my apiary a number of times, I have been compelled to adopt some method of protection for the bees. While I have had excellent luck in wintering in the cellar, my last winter's experience with the cellar was dis-

astrous. But bees outdoors need protection. Although I have wintered bees on their summer stands in common single-walled hives with no loss, yet at other times I have had severe losses by this method also, and feel that this is to be discouraged as much as possible. The following is my way of making a winter-case. The only claim I make for it is that of cheapness and simplicity of construction. These are, in the writer's opinion, very important if they can be combined with ample protection.

Expenses make the profits smaller, and, after all, it is profits that most of us are after. An ordinary person can make a case to hold 12 colonies (eight-frame) in less than an hour. The materials required are four boards 1 x 12 x 18 (for 12 colonies); one 2 x 4 x 12; about 70 feet of 1 x 6 x 18 boards, and enough roofing-paper to cover as many cases as required. The 12-inch boards are nailed together with cleats, and form the front and back of the case. The front is now marked off, allowing 18 inches for each hive. In the center of each space, from left to right, the entrance is made $\frac{3}{8}$ x 8 inches. Cut the 2 x 4 into four pieces 36 inches long, and, selecting a level piece of ground, lay them flat and use the six-inch boards to cover them, forming the floor. The sides are set up, the ends boxed up, and a lath nailed across in the middle on top to keep it from spreading when the

packing is put in. The front should be set back three inches from the edge of the floor to form the alighting-board. This can be seen in the illustration, which shows the complete case. The sides should be toe-nailed to the floor in a few places to prevent spreading at the bottom.

The other picture shows the entrance cover which connects the hive entrance with the outside entrance, and allows packing the front of the hive. It should fit over the front of the hive-bottom instead of resting on it as in the picture, and extend forward $1\frac{1}{2}$ inches further than the bottom-board, so that the bottom-board may not stop up the outside entrance. If it is made this way it will prevent mice getting in the hives from the packing. In practice the entrance cover is slipped over the hive entrance, and the hive pushed forward so that the cover fits tight against the hive and the case. The case is two feet high, and gives room for a comb-honey super on the hive, which is filled with packing with a piece of burlap over the frame. I put a cover on the super and

Entrance protector to fit over the front of the bottom-board. This keeps the packing material in the winter case from filling up the entrance of the hive.

leave a small wisp of straw under one side so as to give some ventilation upward. Packing is put on top of the hives, and rounded up slightly, and the roofing paper is then put on. The case should measure 31 inches wide outside.

When spring comes one can tear down the case, and use the boards for other purposes, or store them away out of the weather for future use.

TWO SUCCESSFUL EXPERIMENTS IN INTRODUCING QUEENS BY THE SMOKE METHOD

BY C. D. CHENEY

There being just now considerable mention of the Miller smoke method for introducing queens, the following may be of interest:

One Saturday a thorough examination of No. 9 was made. One fine frame of hatching brood was found, but not an egg nor the queen. Not being entirely satisfied, another examination was made on Monday, with the assistance of another person, but the results were the same. There were no eggs, no unsealed brood, and no queen. The colony was of medium strength. I mailed an order for another queen (it being then

Aug. 25), after which I watched that hive. After a day or two I became convinced there must be a queen there nevertheless.

A queen came by mail on Saturday. The weather was hot and sultry, and the queen appeared very much exhausted. She was very large, evidently having been taken off the combs while actively engaged in laying, and had suffered severely in consequence.

Before introducing the new queen I decided to have another "look" for the original queen, and, sure enough, there she was, looking as fine and prosperous as could be desired. However, as it appeared that she was not "on her job" I caged her, and within 20 minutes "smoked" the new one in. I observed that she was very sluggish but I hoped she would revive when again placed among natural surroundings. On

FIG. 2.—Scholl's group of five hives with supers and covers placed on in a "jiffy." See "Beekeeping in the Southwest" for last issue.

Chicken colony house containing colonies of bees packed for winter.

Monday I opened the hive, and almost at once found her. She was barely able to cling to the comb, and within a few seconds the bees surrounded her rather roughly, though a little smoke dispersed them. A further search disclosed about a dozen queen-cells, each well extended and containing a larva. I destroyed every cell, and closed the hive. Then I sat down to think it over about as follows. The smoke introduction was very evidently a success; the bees must have recognized at once the condition of the new queen, and gone to work actively and very promptly to avoid probable queenlessness. The original queen must have begun laying between my second and third examinations, whereby the colony had eggs for the queen-cells. The new queen is a "goner." The original queen looks fine, and is this season's hatching. There is only one thing to do—put the old lady back on her job. Upon lifting the cover there was the new queen on top of the frames, without an attendant, just able to crawl. She was caged with four or five bees which appeared to attack her in the cage. The original queen was then smoked in at once. That was on Monday. Another examination on Friday showed the queen perfectly at home, and with a very good start at brood-rearing. Every vestige of the dozen queen-cells had been removed and all the breaks repaired.

This little experience presents two points for consideration, viz.: Two successful in-

troductions with smoke under trying conditions, and the risk in mailing queens right off the combs while distended and heavy with eggs. A rest of at least 24 hours might prevent much dissatisfaction and loss.

My regret at losing the queen (representing a good dollar) is considerably tempered by my success with the introduction. This method (which should be named the Miller) is such a saving in time, and appears so logically safe and correct, that I shall practice it until I get a jolt or until something better comes along, which doesn't seem likely.

New Jersey.

WINTERING TWELVE COLONIES IN A CHICKEN COLONY HOUSE

BY J. NIELSON

The illustration shows a cheap way of packing bees. The colony house is used in summer for chickens, and makes a fine place for bees in winter. This one house holds 12 eight-frame hives, six facing east and six west, with four inches of kiln-dried planer-shavings packed around them. The cover of each hive is taken off, and a tray with a burlap bottom over a two-inch bridge across the frames put on instead. The tray is filled with shavings, and then a tar-felt cap put over; so if the weather should prove bad when I take the hives out they will still be well protected against cold spring rains.

Apiary of Elias Fox, Union Center, Wis.

These were all given a good feed of sugar syrup with two parts of sugar and one part of water, and all just brought to a boil on the stove. There has been brood-rearing going on all winter here, and my bees that I have packed away in this colony house are stronger now with bees than last December, when I packed them. I got from two to four supers of comb honey per colony, selling at \$4.20 for 24 sections without crates, and \$40.00 worth of extracted honey. I had ten colonies last spring, and five of them were very weak.

Plattsmouth, Neb.

A TEN-ACRE FARM PAID FOR BY THE BEES

BY ELIAS FOX

Under separate cover I am sending a photo of my home here, showing a portion of my apiary. Only little over half the yard shows. I could not get it all in on account of the fence at the lower side. Neither could I show the honey-house, which stands at the right, just out of sight, in front of me. It was my intention to have the picture taken before the extracting-supers were removed, but the photographer was away.

I have here a ten-acre farm bought by my bees. My crop during 1912 was 10,500 lbs., principally all clover, from 100, spring count. I wintered 143 colonies in the cellar under the house, in No. 1 condition. My best colony gave me a surplus of 235 lbs. of honey, and swarmed besides. There was also plenty of honey left for winter.

Union Center, Wis.

A GOOD BEE-CELLAR A PAYING INVESTMENT

BY E. S. MILLER

In making a bee-cellar I would recommend the use of solid concrete—not cement blocks or brick if it is to be in clay ground, for the reason that they crack apart by action of the frost, and let in water. Nor do I believe that, as a rule, it will pay to use wooden construction anywhere if one owns the land and expects to continue in bee-keeping. I would have a cement floor sloping to a drain at the center; a ceiling lathed and plastered, and made as nearly air-tight as possible; double window shutters and doors. There should be a good honey-house above, and a chimney extending from the cellar-bottom on the east or leeward side to take the air from the bottom of the cellar.

A subearth air intake at least ten inches in diameter should reach from a point 100 feet or more on the west or windward side, and enter at the bottom.

The spaces between joists above the cellar should be filled with dry sawdust or other suitable insulating material. The cellar for 100 colonies should be 16 x 20, and 7½ feet deep.

Will it pay to build such a cellar? A good concrete cellar of this size, properly constructed, will cost approximately \$300. One man can put in 100 colonies in half a day, and take them out in the spring in about the same time. The cost of wintering would then be something like this:

Interest on investment at 6 per cent.....	\$18.00
Labor, putting in and taking out.....	3.00
Winter losses, 1 per cent.....	5.00
Depreciation of cellar.....	00.00
Depreciation of hives.....	00.00
Consumption of stores, 15 lbs. at 6 cts.....	90.00
Total, 100 colonies.....	\$116.00
Cost per colony.....	1.16

Now figure the same items when bees are packed outside, counting interest and depreciation on outer cases, and remembering that the consumption of stores will be about double.

It would seem that a careful consideration of these items will show that it is much more economical to put money into good standard hives and a good cellar than to expend it for thin outer casings or double-walled affairs with the consequent additional labor, depreciation, consumption of stores, and losses of colonies.

Valparaiso, Ind.

THE COLOR SENSE OF BEES

A Series of Interesting Experiments Showing that Angry Bees will Sting Black More than they will White; Bees Not Reflex Machines

BY JOHN H. LOVELL.

Mr. A. C. Miller's recent article, July 15, p. 487, on the relation of bees to black, seems to invite a reply. No doubt the sense of smell is well developed in bees. Although it has not yet been shown to be better than the visual sense, Forel and others have held the contrary. Certain odors bees find pleasing, others offensive. Cases where irritated bees sting objects because of their disagreeable smell may be at once dismissed. Some time ago Dr. C. C. Miller quoted the editor of the *Irish Bee Journal* to the effect that persons not cleanly in their clothing are often badly stung. Such discrimination is certainly to the credit of the bees.

"Bees like black," asserts Mr. Miller. Lubbock and Herman Muller both claimed

that bees preferred blue to other hues; but there are to-day few if any naturalists who believe that bees find an esthetic pleasure in blue coloration. Black is produced by the absorption of all the rays of light. There are none reflected to give pleasure or pain. Life is dependent upon light; and an animal or plant placed in absolute darkness will soon perish. The terrible sufferings of convicts confined in the dark cell have been graphically described by Charles Reade in "It is Never Too Late to Mend." It would seem to be impossible to imagine how a piece of black cloth or a black box could give pleasure to any animal. There never has been furnished, nor does Miller furnish, nor do I believe there ever will be furnished, a jot of evidence that bees like black.

I do not believe that bees are reflex machines. They possess at least a small amount of intelligence, defining intelligence in its beginnings in the words of Forel and others as the power of associating different sense impressions and instinctively making simple inferences. Bees observe and learn from experience, which they subsequently remember. I can not for a moment suppose that Mr. Miller believes that the fact that black bees are not stung to death by Italians, or that black insects belonging to other families are not attacked by bees, is evidence that they either like or dislike black. Huxley, after perpetrating in his letters a pun or an ambiguous joke, not infrequently followed it by the parenthesis "(Now, that is a 'goak')." Mr. Miller should have labeled the above statement "a goak." Usually, probably always, bees do not sting a black object unless it irritates or annoys them. A hive of gentle bees managed on the let-alone plan will hardly sting any thing.

The illustrations of black hogs and cows pastured near apiaries are not pertinent. The hives were fenced around with wire netting, and the animals could not come near enough to do any injury. Very likely they did receive some stings at first; but the bees speedily learned that there was no occasion for them to sacrifice their lives. A friend of mine keeps his hives, which are surrounded by a wire netting not over two feet high, in his hen-yard. When I last inspected them there were hens close to the netting; but neither hens nor bees paid any attention or manifested any fear of each other. It will be remembered that I hold that honey-bees neither like nor dislike black; but that, when angered, they will sting animals and human beings which are wholly or partially covered with black much more than they would if they were clothed in white, because they are more clearly seen.

Exception must also be taken to the statement that it is doubtful whether a sudden change from dark to light or *vice versa* affects a bee's vision at all as it does ours. The eyes of bees are of great size, and are highly developed. I know of no one else in America who has so carefully investigated their structure as Dr. E. F. Phillips, of the Bureau of Entomology at Washington. His figures show that each eye tube of the compound eye is connected by a nerve fiber to large and powerful optic lobes. There is, in my judgment, not the slightest reason to doubt that this highly specialized apparatus is strongly responsive to waves of light. Their impact incites molecular changes in the nerve fibers as certainly as a magnet influences the compass needle.

The experiments with the little house or tent of white cloth are of much interest in that they show that the flight of bees is influenced by the line of the horizon. In their endeavors to escape, the bees flew against the translucent walls always above the horizon line dimly visible through the white cloth. Buttel-Reepen gives an instance where bees at liberty showed by their manner of flight that they perceived the horizon line and were influenced by it. I regard this as good evidence that the compound eyes of bees can see distant objects.

In the experiment where there were four hives, one on the middle of each side of the room, I should attribute the ability of each bee to find its own hive to its memory of location. The late W. Z. Hutchinson once wrote me, giving an account of some observations showing that bees in their flight were strongly influenced by locality as well as by color. Buttel-Reepen also considers that memory of locality is very strongly exhibited by scouting bees. As an alternative there is, of course, the theory of Bethe, that bees are led back to the hive by an unknown force which draws them as a magnet draws steel. It is open, indeed, to the objection that there is no evidence of the existence of such a force. Or if one prefers he may believe with Fabre that they are guided by a sixth sense.

Personally I believe that bees flying out from the darkness of the hive see black objects much more clearly than they do white, which reflect all the rays of light. In the brilliant light of a mid-summer day a white object may easily escape attention. Our railroads do not use white signals in the daytime, but black. Newspapers and books are printed in black letters. In the arctic regions in winter, birds escape attention by their white plumage and mammals by their white fur. There are numerous instances where persons have attempted to pass

through a mirror, which largely reflects light, as through an open door; but no one, when the sun was shining, ever tried to walk into a black wall.

Mr. Crane did not exaggerate one iota when he said that it was the almost universal opinion among beekeepers that a black object is more likely to be stung than a white one. The recent articles by Mr. F. J. Cartan, of Oregon, and "The Beeman," hailing from New Mexico, show how widely disseminated is this view. The testimony cited in my paper was that of entirely trustworthy witnesses, including beekeepers interested in the subject chiefly from the commercial point of view, as well as the editors of GLEANINGS, Dr. C. C. Miller, Messrs. Crane, Townsend, and others. I infer from a personal letter received from Mr. Dadant some months ago that he also holds a similar opinion. Mr. A. C. Miller offers no reply to this evidence; he simply seeks to ridicule it. I am a naturalist; and while I do not consider it necessary to verify every observation when there is ample confirmatory evidence in its favor, yet when it is called in question it is my custom to appeal at once directly to nature by experiment.

The following experiments were made August 7, 1913, at 10 o'clock. The day was clear and calm, and the temperature in the shade was 80 degrees F. I was dressed wholly in white, but there was a black veil on my broad-brimmed straw hat. The white sleeves of my shirt were buttoned outside of a pair of yellowish-white gloves. Midway on the sleeve of my right arm there was sewed a band of black Cashmere cloth, ten inches wide, entirely encompassing the sleeve. No smoker was used, as it was desired that the bees should display their natural disposition.

Thus dressed I approached a hive of black bees, and, kneeling on the ground in front of the hive, I tapped vigorously with both hands on the top of the hive-stand. A large number of bees presently flew out of the entrance, many of which immediately attacked the black band on my right arm, while the left sleeve, which was entirely white, was scarcely noticed.

On the second story of this hive there was a super containing large pieces of partially filled honeycomb given to the bees to clean up. Standing on the west side of the hive, and facing the east so that the sun shone directly on both my extended arms, I lifted off the cover, and, introducing both hands into the super, lifted a piece of comb covered with bees and gently shook it. Instantly many bees flew toward me. A large number attacked the black band, to which

they were constantly coming so long as my hands remained in the super and disturbed them. An individual bee would not remain long upon the black band, but would soon fly against my veil, or circle about my head. So far as I could observe not a single bee attempted to sting the left white sleeve, and very few even alighted upon it. I closed the experience by walking away from the hive.

This experiment was repeated a second and a third time. During the second experiment I estimated the number of bees on the black band at a certain moment about thirty (I intentionally make the estimate smaller than I believe it to have actually been), while the left sleeve was almost wholly unnoticed. As in the previous experiment, the bees soon flew from the black band to the black veil, or circled about my head. So fierce was the attack that I found it advisable to withdraw to some distance. My third experiment yielded similar results to the two already described. I can not imagine how certain of the bees could have made greater efforts to sting the black band than they did. They seemed fairly beside themselves. To that part of my dress which was white the bees gave very little attention.

I now deemed it advisable to have a witness. A friend was summoned, and provided with a black veil and a pair of white gloves. She was stationed less than ten feet away, directly facing me, so that the behavior of the bees could easily be observed, and individual bees be plainly seen in the bright sunlight. Removing the cover I plunged both hands simultaneously into the super, which was overflowing with bees. What happened I will describe briefly in the words of my friend:

"A great many bees immediately flew to the black band on your right arm, although by no means all of the bees which left the super. I should estimate that there were at one time as many as forty on the black cloth. They were continually coming from the super to the black band, but they did not remain long upon it. I did not see a single bee upon your left sleeve, which was wholly white. There were hundreds of bees flying about your head or on your veil."

On August 12 I continued my experiments. The morning was calm and clear, and the temperature 76 degrees F. With the exception of a black veil I was dressed all in white; but on this occasion the band of black cloth, 10 inches wide, was sewed about my left arm instead of around the right sleeve as in the previous experiments.

At 10 A.M., facing the east as before, I lifted the cover from the same hive as in the experiments of August 7. As soon as a piece of honeycomb was shaken with both

hands a large number of bees flew furiously at the black band and endeavored to sting it. Only two or three bees were seen on the white sleeve of my right arm, and they did not attempt to sting. Both from the black piece of cloth and from the open super a great number of bees flew against the black veil. I then withdrew to a distance.

A little later I again approached the hive; and as soon as the combs were shaken a cloud of bees flew fiercely at me. At one time a part of the black band was almost literally covered with furiously stinging bees, and the black veil was assailed by hundreds. The right sleeve, wholly in white, and the other portions of my dress in white, received very little attention. As I walked away the bees followed me for a long distance. A third experiment yielded similar results.

I next opened another hive on the opposite side of my apiary. When I began thumping on the frames the bees at once attacked the black band and the black veil; but the right sleeve and the other white portions of my dress received little attention.

I now left the apiary and substituted for the black veil a new white veil which I had procured for this purpose. On my return the bees, as previously, sought to sting the black band; but the white veil was less attacked than the black. The difference was most astonishing. Whereas hundreds had before sought to penetrate the black veil, the number now was so small as to cause me no inconvenience. Those which did attack seemed much less persistent.

A third hive was opened. The black band on my left arm was furiously attacked as in all the previous experiments of August 12; but the white veil enjoyed much greater immunity from the attack than the black. So great was the difference that I propose hereafter when working among my bees to wear a white veil.

As a result of these experiments I have no hesitation in saying that beekeepers should always, when at work in the apiary, dress in white. The white veil which I used was made of mosquito-netting; and while I could not see through it as easily as through the black when looking at objects at a distance, there was little difference when I looked directly downward at the hive or the ground. Very likely some other material would give better results in this respect.

The results obtained in this series of experiments are most interesting and noteworthy. It is the first instance, so far as is known to me, where it has been shown conclusively by means of experiments performed directly for that purpose that angry bees discriminate against black. Strong colonies

of black bees were employed whose inmates were of a pugnacious disposition. While I had great confidence in the entire reliability of the observations cited in my previous article, the discrimination of the bees against black was far more decisive than I expected. Incidentally I take pleasure in extending my thanks to Mr. Miller for his criticisms, which led to the planning of the above experiments. They have opened a field for further work which I am hopeful will prove of value.

I do not consider that the series of experiments described above proves either that bees "like" white or "dislike" black. Their purpose was to sting the disturber of the colony. As they flew out of the super or hive, the band of black cloth most strongly attracted their attention, and became the chief point of their attack. Discovering their inability to sting through it they did not remain long upon it, but sought to reach me through the black veil. The sleeve which was wholly white was hardly molested because it escaped attention. In comparison with the piece of black cloth it was inconspicuous. For the same reason the white veil was less fiercely assailed than the black one. The behavior of the bees does not, therefore, indicate hostility to black or preference for white.

Waldoboro, Me.

[Mr. R. F. Holtermann, who paid us a visit a few days ago, remarked in the course of his conversation that there was one of his men who persisted in wearing a black felt hat; that he finally had to tell him that he would have to wear a white or a straw hat, the same as all the other men wore. He went on to explain that this black hat was constantly inviting angry bees; that it was the practice of him and all of his men to wear light clothing, not only to prevent stings but to stop would-be cross bees from following about.]

Some two or three years ago, Jay Smith, of Vincennes, Ind., told how a couple of dogs, one black and one white, went cavorting through the beeyard. The black dog was badly stung while the white one was not molested at all.—Ed.]

duced in that way I found two balled three days after, and queen-cells started. After making the bees release the queens, and destroying cells, they were finally accepted, although they still persisted in superseding.

Regarding virgin queens, I can give a plan that I have used without the loss of a single one, regardless of age. Here it is. I use the regular hive full depth, with division-board forming a twin nucleus, with $\frac{3}{4}$ -inch flight-hole at opposite ends. When I have a batch of old virgins I go to a colony having sealed brood over an excluder; brush all the bees off, and extract the honey. I replace it for the bees to clean up; then I take one frame of this brood with adhering bees and replace it in one side of the twin nucleus. I add an extracting-comb partly filled with sugar syrup, and plug the entrance with grass. I leave them confined till evening. By that time the bees will have gorged themselves to the limit, and will be crowding around like a flock of sheep. I then remove the grass from the entrance and run the virgin in and plug it again for a few minutes. I might add that the entrance should be plugged again early in the morning, as some of the old bees going home with their load of syrup will have marked the spot and return for more if during a honey-dearth. About 10 o'clock I open the entrance, and the bees by that time will have settled down to normal. I have never lost a single queen introduced in this way.

If your friends who have used the smoke plan for introducing laying queens will take the trouble to look those frames over they will, in a good many cases, find the queens laying and the bees raising supersedure cells.

I have had several young queens that were introduced safely, and had laid four or five frames of eggs, superseded about 12 days after introducing. I believe it is always best to look through a hive and to destroy the cells nine days after killing the old queen, as I am sure that at least a fourth of the queens introduced are superseded that could probably be saved if those cells were not allowed to hatch.

INTRODUCING VIRGINS REGARDLESS OF AGE

Danger of Supersedure of Queen in Smoke Method of Introduction

BY J. A. M'KINNON

Your editorial Sept. 1 regarding the smoking plan of introducing queens, while it is about the best I have yet tried, it is not always certain. Out of four queens intro-

Convention Notice

The 23d annual meeting of the Illinois State Beekeepers' Association will be held at the State House, Nov. 5, 6, 1913. Prizes will be given as follows: \$5, \$4, \$3, and \$2 for 1st, 2d, 3d, and 4th best essays to be read by the writers, and not to exceed 500 words. See page 83 of last (12th) annual report, or write to the secretary for particulars. The report of this meeting will go largely to make up our 13th annual report, of which every member will get a cloth-bound copy. Further individual notices will be sent to all the members.

Heads of Grain from Different Fields

Good Yield of Honey in Spite of the Dry Weather

This has been the best year we have had for five or six years past in spite of the drouth which has cut crops at least in half, and the fact that there was no dew nights at all. What few bees there are left, that were taken care of and looked after, have yielded a profit to beat Standard Oil stocks.

May 10 I bought a colony for \$2.00. The lower story was well filled. I moved the bees three miles home, and on the 14th I put on a case of sections for them. Up to date I have sold 66 sections of honey from that colony. These sections test from 17 to 18 ounces each, so I have sold them by the section at 18 cents. I still have fifty or more sections ready to move at any time from those bees. I have been unable to fathom the source of the supply. I know of some alsike-clover fields, some two or three miles from us, that I have thought probably were where a part of it came from. One man claims that the red clover was so rich in nectar that it was actually dripping from the petals on dewless mornings when he went into the clover-fields for the stock. Any way, we are getting the goods, and the honey is of fine quality. Others did as well as myself in securing good yields.

So far as I have learned, there have been few swarms. Some careless ones that neglected their bees came to get sections for them after the flow was past. To be sure, a part of our flow was from the once despised sweet clover, but now looked upon by the farmers in quite a different light. One man this year has sown twelve acres for fertilizing, and others will follow his example. Alfalfa is also getting started, so that we hope in the not distant future that the good honey-pastures of former days will come again, and that commercial beekeeping will be as profitable as it once was.

Bees Winter Better When a Way of Escape for the Moisture is Provided

I have tried the plan of wintering my bees in the cellar and also out of doors. In either case I usually found the combs wet and damp in the spring; and often water would run out of the front of the hive, and ice form on the bottom-board.

Four years ago in December I bought four colonies of bees—big strong colonies with an abundance of honey. They were in two-story home-made hives. They had gunny sack over the top under a make-shift cover. Some of them were open at the corners, and the covers were loose. Yet those bees were ready to come out at any time the hive was disturbed in the least. No water ran out of the entrance, and there was no frost inside the hive. They stood right out of doors where I put them when they were brought to my place, and they went through some 40 degrees below zero all right.

I have cut twenty or twenty-five bee-trees here in Montana. Invariably in these trees the entrance is at the top of the cavity. I have read the discussions in GLEANINGS regarding sealed covers, absorbent cushions, etc. However, last fall I made a winter house. It is 16 feet long, 30 inches wide, and high enough to put in a double-story hive if I wish. I placed my hive without bottom-board on cleats on the bottom, and bored a $\frac{3}{8}$ -inch hole in the back end of the covers, and packed the extra space with alfalfa hay, coarse remains from the cows' manger, and set a plank slanting in front of the entrances.

When I opened the hives early in March I never saw a drier or cleaner lot of combs and hives for that time of the year. The dead bees on the bottom were dry and clean, and the bees wintered well. Some were getting short of stores, which I find is frequently the case in Danzenbaker hives. However,

I had reserve combs for them. As elsewhere, the winter here was not severe.

From the above observations and experience I am of the opinion that it is better to let the moisture out, and keep the hive dry than to keep the moisture in and have the hive damp, and a lot of wet ill-smelling dead bees on the bottom-board.

Belgrade, Mont., April 16. C. A. KINSEY.

Bees Packed for Winter so as to Allow Escape of Moisture from Hives

I have kept bees for some time, and have always had marked success in wintering them. I use a telescope cover for the hives, with a three-inch space on the four sides, and a four-inch space for the top. In the air space I pack planer shavings; and just before covering the top of the hive with the shavings I raise the lid and slip a ten-penny nail between the lid and the hive body. This allows the moisture to pass out and to be absorbed by the shavings. In the spring, when I unpack the colonies I find them nice and dry without any moldy combs. As a rule the shavings are very wet, even down half way along the sides.

Last winter I put 23 colonies into winter quarters, four being quite weak. When I removed the telescope covers late in March I found the bees in excellent condition with the exception of the four weak colonies, and did not lose a colony.

Some of the hives were as full of bees as is usual the first of May.

One hive in particular was so strong that I had to lift out the frames, and a pleasing sight met my eyes—a nice lot of brood was started, and one frame in which the brood was sealed, and this March 20. This seems especially remarkable as the climate up here on the mountains is rather cold, and the seasons are slow, it being a rule that fruit bloom is ten days to two weeks earlier west and a little south.

Philipsburg, Pa., March 20. W. N. ZEITLER.

A Word of Explanation About Feeding Back to Secure Well Finished Sections

On page 564, Aug. 15, Mr. J. E. Crane asks whether there is not some mistake about getting 15 to 25 supers per colony finished by feeding back in the two or three weeks between clover and heartsease. This statement was based on memory, as I have not kept an exact record; and while I am quite certain one can count on 15 supers in three weeks per colony, yet it might be too much to count on 25. As I said, the character of the colony and weather conditions govern the amount finished. But with hot weather, strong colonies, and plenty of feeder surface, the section work goes very rapidly. We run up to five or six supers to the hive after a few feeds, and look the supers over about every other day, and add new ones next to the brood-chamber, or else heavy feeding will bulge the sections already on.

The bees must have plenty of room to store; and as fast as the partly finished sections are about drawn out, more partly built ones must be added. As regards the time, one usually has more than two or three weeks, especially in years when it becomes necessary to feed back. Frequently the early flow closes July 1 to 10, and perhaps no fall flow, to amount to any thing for section work, follows.

Such seasons are the ones when there are apt to be unfinished sections. We can begin a little before the flow ceases, and continue into the fall flow if it is light, so we really have perhaps nearer a month for this work than two or three weeks. I may have had the idea of counting on 15 to 25 supers per colony, and failed to state it clearly.

There is so much variation in the conduct of bees

from year to year that it is difficult to write of them so as to be understood. Sometimes they fill the brood-combs very heavily when fed to finish sections, and at other times not a great deal is stored there. My thought was to give a general idea of how to get partly built sections finished, and about how fast we could count on doing it, and let every one work out the details, varying them according to the need of the different seasons and localities. At this date, Aug. 20, I am feeding back to two colonies, and the work is going well; but as the early flow lasted until August, and tapered off very gradually, I had only 15 or 20 supers to feed back.

The Water-bottle for Queen-cages; a Good Testimonial from One of the Old Veterans

I am glad to see that you are going to add a water-bottle to your queen-cages. Years ago I bought of A. I. Root an imported queen, and home-bred queens all came through in good shape with their little water-bottles. Contrast this with the present method. Queens I bought of Messrs. Moore, Robey, and Hand all came dead. I suggested softer candy to two of the gentlemen, and the next queens came through alive. More than half the queens shipped here are dead on arrival. I know a man who returned queens four times to the same shipper. The fifth came dead, and he let it go at that—said he was ashamed to return her. All of these queens could have been saved if shipped as Mr. Root shipped them 35 years ago.

I question whether we have improved the frame designed by A. I. Root. I had some two thousand combs built in these trussed frames. There was no sagging of the top or bottom bar unless the wire broke. This is more than I can say of the frames I have now.

Bakersfield, Cal.

C. G. KNOWLES.

[My good friend, I am greatly pleased to see your indorsement of my queen-cages and frames of olden times. If I am correct, the preference seems to be strong for a heavier top-bar; and with these heavy top-bars the wire trussing I devised seems to be unnecessary. The heavy top-bar (an inch thick or more) does away with burr combs over the frames to a great extent. See A B C book, p. 130, for a full discussion of the matter.—A. I. R.]

The Smoke Method of Introduction Again Successful

When I received queen No. 2 I removed the old queen from a small colony of what I would consider pure blacks and laid the new queen on top of the frames. In 24 hours I looked in and found the queen still in the cage, but the bees had balled her and were stinging and biting her. I made the discovery that they had started many queen-cells. I said, "You are not going to kill that queen," and I plugged up the hole in the candy so that they could not reach her, destroyed the cells, and placed the queen back on the frames. The next day I found the same conditions and again destroyed the cells. The next day it was the same, and I concluded to try Arthur C. Miller's plan of introducing as given in GLEANINGS, June 1, p. 370. I did not tear the cells down, but administered the smoke as directed, and released the queen. I left them alone two days and looked in, and there was the queen as contented as if she had been raised there. The bees that came with her were also there. This is the first time that I ever had a swarm build queen-cells when there was a laying queen caged in the hive immediately after the removal of the old queen. I am also sure that I would have failed with any method that I have previously tried in introducing.

I never have read a report of the effect of a high

dry altitude on the candy in a queen-cage. It sometimes becomes so hard that I doubt if the bees would get it out in a week. I had this experience in Fallon, Nevada, last year.

C. E. HAMMOND.

Vivian, La., Aug. 8.

Sac Brood

I am writing you in regard to sac brood. Something got wrong with my bees, and I sent two samples of brood at different times from two hives that were affected to Dr. Phillips, at Washington, and both times he reported sac brood, and said that it was not serious, and no treatment was recommended. The two colonies affected were weak, so I burned them before I got his answer, thinking I had foul brood. I have a colony now that was affected with only a few larvæ in one comb, so that I cut them out and am writing you to see what I must do to them.

ROSCOE McELROY.

Morganfield, Ky., Aug. 18.

[Sac brood is not dangerous nor contagious, or at least only slightly so. We are sorry that you burned up your colonies. It is found in the height of the season in most apiaries in the United States. It usually disappears in a short time, and the only damage it does is to kill half a dozen or so larvæ out of possibly twenty-five or thirty thousand other individual larvæ in the hive. Such loss is hardly worth taking into account. If you will apply to Dr. E. F. Phillips he will send you a government bulletin on sac brood. Address him, Department of Agriculture, Washington, D. C.—Ed.]

Meeting of the Carolina Beekeepers' Association

The Carolina Beekeepers' Association held its mid-summer meeting in the convention room of the Langrenhold, Asheville, N. C., July 26. The meeting was one of unusual interest. O. Brumfield, J. W. Gooderyn, and others discussed the merits of the ten-frame hive over that of the eight frame, with the result that each hive had an equal number of advocates.

Dr. B. F. Landis talked on the subject of the best bee for the South. A discussion followed, and the matter was settled in favor of the pure Italian.

C. W. Harmon, a packer and dealer in fine honey, gave the convention a treat as to the best methods of preparing our product for the market.

Our society has doubled its membership in less than 12 months. The next meeting will be held in Black Mountain, N. C., Aug. 29, at which time new officers will be elected.

A. L. BEACH, Sec.

Virgins Lost Because of High Wind

Your editorial, August 1, page 513, states that a high wind July 13 and 14 left your queen-rearing yard almost queenless. I have had trouble this season. I have been replacing virgins continually that went somewhere. We have had a great many high winds preceding storms, and at other times. I can now understand why so many have been lost.

Cranbrook, B. C.

T. S. GILL.

Sweet Clover and Alfalfa Stood the Drouth

This has been a dry year. We did not get any rain this summer. The bees did better than they did before for eleven years. Some for the last three years did not make their own living. Through all the dry weather the sweet clover and alfalfa did finely. This is the first year the alfalfa ever honeyed. I have got 26 hives. My best hive made 115 pounds, and some made nothing. I will get your A B C book and raise by own queens next year.

Fredonia, Kan., Aug. 26.

CHAS. HEROLD.

Our Homes

A. I. Root

Seek ye first the kingdom of God, and his righteousness, and all these things shall be added unto you.—MATT. 6:33.

Lay not up treasures for yourselves upon earth, where moth and rust doth corrupt, and where thieves break through and steal.—MATT. 6:19.

In our last issue, page 663, I suggested to our good friend Doolittle that if the world could be taught the importance of seeking *first* the kingdom of God and his righteousness, all our State and national troubles would be ended; but thinking it over since then I am led to believe that I did not half realize what I was saying. Let us consider the matter a little. What is the world just now seeking? My good friend, what are *you* seeking? And, to come still nearer home, I have been asking myself what am I seeking? I have told you several times in years past, that my thought was largely devoted to hunting up "God gifts." There is a great deal said about the "high cost of living of late;" and several have suggested that we had better put it "the cost of *high* living," putting the emphasis on the word "high." Well, I have found enjoyment and happiness—yes, great happiness—by showing the readers of GLEANINGS how they could live and keep in good health without having it cost all one can earn. Our friend Terry has given us excellent lessons and suggestions along this line; and I fear a great many of us, men and women, have mistaken and exaggerated ideas in regard to what we must have to be decent and respectable. When I talked about having a little mill and grinding our own flour and wheat so as to have *better* and *cheaper* food, a great many were inclined to sneer at the idea. Let me branch off a little right here.

The good people in Cleveland have inaugurated what they call the "Fresh-air Club." They gather up a lot of poor children during the hot summer months and send them out into the country to get fresh air and outdoor exercise. This society asks the country people to take one or more of these children. For several years quite a few have come here to Medina. Now, this is all right. It is a splendid undertaking. Keeping these children free of charge for two or three weeks is, *without question*, seeking the kingdom of God and his righteousness, instead of living altogether for self; and I hardly need tell you that self and selfish interests are not "God's kingdom" by any means. It is something of a task to take two or three youngsters, brought up in the streets of a large city, and make them inmates of your home. If you have tried it you know something about

it. There is a difference in children, of course. Some will meddle with and destroy things, and have to be watched almost constantly. Others, who have been properly brought up, will be orderly and helpful. Now comes my point:

A couple of children that came from the city were taken by a family of moderate means. Pretty soon the children began to grumble, and they grumbled at having steel knives and forks on the table. They had not been used to that way of living. In another case a family of moderate means undertook to care for three children. I believe, however, that somebody who was abundantly able paid for the board and lodging of two of the three. Well, one little girl one day volunteered the information that her pa in the city received quite a little higher wages than the man who had volunteered to help care for the poor children!

I have related the above incidents to show you that even the children have exaggerated ideas of how we ought to live. Their parents, evidently, had not been seeking first God's kingdom and his righteousness.

Since we have been discussing the problem of the high cost of living, somebody has suggested that the "high cost of dying" ought to receive some attention. When my good friend Metcalf helped us to put the Anti-saloon League on its feet something over twenty years ago, he gave liberally, and also gave repeatedly, to get the new organization under way. He was always giving for praiseworthy undertakings all his life; but when he came to die he protested against money that might do good being buried up and wasted on an expensive coffin. He put a clause in his will saying that his coffin must not cost over \$25.00. I am told that, when the friends went to the undertaker's, they could not find any kind of coffin so cheap. You who have paid funeral bills know how it is in your own locality. An article in the Cleveland *Plain Dealer* of a recent date intimated that there is a combine among undertakers, and that they have a peculiar opportunity to combine, because no one ever disputes or questions the correctness of funeral bills.

Our friends will recall that, for a great part of my life, I was an enthusiast on greenhouses; but of late I have gradually lost my interest in them. Shall I tell you why? Because the greenhouses nowadays are mostly devoted to growing stuff for funerals. I have seen a wagonload of beautiful and expensive flowers thrown away at the funeral of a comparatively common-

place individual. I do not know whether these flowers are buried with the remains or whether they are dumped in a heap in the back yard. I believe, however, that seldom is any use made of them. I have all along protested against these customs, because I have happened to know that a great many times the bereaved family sadly needed the money that was just literally "dumped" into the fire. In olden times it was customary to bury things with the departed loved one, thinking he or she might need them. The Indians had a tomahawk and bow and arrow put in the grave, thinking the dead warrior might need them in the new hunting-grounds. And I believe the heathen in some nations still put in food for sustenance during the "trip across the dark river." While there are starving people by the hundreds and thousands in different parts of the world, great sums of money are buried in the ground where they can not possibly do anybody any good.

I have said more on this line of my subject than I intended; but is this sort of work seeking the kingdom of God and his righteousness? and is it "laying up treasures in heaven"? The Savior urged us, you remember, to put our treasure where it will not rust, and where it can not be stolen by thieves. Are we doing this? Here is a clipping from the *Cleveland Plain Dealer* of Sept. 11. Read it, and see what you think of it:

PAYS \$30,000 FOR BEAUTY; ASTOR'S WIDOW INSTALLS LUXURIOUS ROOM ADJOINING BED-CHAMBER.

NEW YORK, Sept. 10.—Mrs. Madeline Force Astor, widow of John Jacob Astor, will remain beautiful if a \$30,000 beauty parlor can effect that end. She has installed an electric beauty room on the second floor of her Fifth Ave. home, adjoining her bedroom.

The room, 9 by 15, is the quintessence of luxury. The white tiled floor is concealed by an oriental rug, while paintings, plate mirrors outlined in gold, and concealed lights are in the room. Gold and pearl are used wherever possible.

A modified barber-chair is in the center for use during the hair-dressing, massage, and other operations of the beauty doctor.

The world knows little or nothing about Mrs. Astor; but the world does know very much about John Jacob Astor. Has this woman ever done any thing for the world that should entitle her to this enormous wealth to spend for self as she chooses? No wonder the hard-working people are forming "unions" and sending up protests against this unequal division of wealth. Now, I am not going to turn socialist just yet. I hope John Jacob Astor secured his great wealth as the result of honest and legitimate trade and traffic. But how about his wife and children? How about thousands, including Thaw, his mother, Diggs, and Caminetti, who are trampling our laws under foot,

and saying virtually to outraged humanity, "Help yourself if you can." As I dictate these words, however, I can thank the Lord that there seems to be a prospect of better things, and, not only that, but Diggs and Caminetti are to go to prison. Of late, however, it transpires that after they are put in prison at great pains and expense, they do not seem to *stay* there. The man who led the gang that lynched and cruelly murdered poor Etherington at Newark, Ohio, is now at liberty again. Notwithstanding the saloon-keepers and liquor-men fought hard and long he was finally sentenced to twenty years in the penitentiary; but when he had been there just *two* years the whisky gang got up a monstrous petition and had him "pardoned out."

Dear friends, it just now occurs to me that I am making a doleful story so far, and may be I had better drop that part of it. It is a comparatively easy matter to point out the faults of others, of our administration, of the way society manages things, etc. But it is a harder matter to reconcile the fact that we are *all* sinful. We are all of us—yes, the best of us—spending a great deal of time and money in seeking other things than God's kingdom and his righteousness. We are more or less selfish; and this same selfishness blocks the way of getting what we are seeking. Thousands are learning a lesson—yes, I think more than ever before. People who have great wealth are, some of them, using that wealth to lay up treasures in heaven.

Instead of seeking first the kingdom of God and his righteousness, there is a new fashion of late, and it would look as though a good many people had adopted, as a motto in business, something like this: "Seek ye first the dollars and cents belonging to your neighbor; and (if he does not make any fuss about it) you will be heaping up treasures for yourselves."

I hardly need remind you of the public officials who, while receiving a liberal salary for looking after the interests of the people at large, accept a bribe for doing just the opposite; and I hardly need remind you of the way in which barbers, dentists, some doctors, perhaps some lawyers, "hold up" their victims if there is nothing in particular to hinder them from doing so. If you go down to Florida, be careful to ask prices in a barber-shop, at the dentist's, at the drugstore. If they have reason to suspect you are a new comer, and are unacquainted with prices and customs, you will be pretty sure to be "bled" unless you make a bargain beforehand. Now, please do not understand me as saying that this is the rule.

There are good Christian people, a lot of them, in Florida and everywhere else, who are *really* seeking "God's kingdom," and *trying* to lay up treasures in heaven. But this fashion of holding up people is in danger of spreading everywhere, among young and old. Let me give you one illustration.

In our capital city of Columbus, Ohio, I stopped to have my shoes shined up a little, after some dusty travel. The boy did a very neat job; and noticing some shoe-laces on a hook by his stand I told him he might replace my old soiled ones with the new. After he had my shoes neatly tied up I asked him how much the bill was. He replied, "Twenty-five cents."

"Why, my young friend, your sign here says, 'Shine, 5 cents.' Do you mean you want 20 cents for a pair of shoe-laces?"

"Yes, that is the price for those extra-nice shoe-laces."

You see the boy was up with the times. He not only had my shoes nicely shined and tied up, but he had me "tied up" also. I could not ask him to undo the laces and hang them up again on the hook, for they would be second-handed. Should I quarrel with the boy, even if he did charge 20 cents for a pair of laces, knowing that two pair just as good are usually sold for a nickel? I imagined his eyes twinkled as he saw that he had me "in a corner." I gave him the quarter, mentally deciding that next time I would stick to my rule of inquiring the price before I invested, even if it were only a pair of laces.

Now, dear friends, it is not only for *your* good, but for the good of every one who has something to sell, that you make it a rule to ask the price beforehand. It will help you and help the other man, or boy, to get nearer to both of the two precious texts we are considering.

Let me suggest to our friends who are writing me letters lately in regard to socialism, that the man who uses his money to start a factory, and gives employment with fair wages to hundreds of men, women, and children, is, in my opinion, laying up treasures in heaven. If the article that he manufactures is better and cheaper, and something that is needed in every-day life, his money is really invested in a way that may be called "treasure in heaven." Suppose this factory is started in a rural community and is for the purpose of manufacturing hoes. If the proprietor secures better steel than has been used before, makes a lighter implement, hunts up better wood for a handle, and if he sells it at a smaller profit than other makers, he does good in two or three ways. First, he gives a poor man a nice hoe for a little money. Then by the inven-

tion of this beautiful bright and shining hoe like the one I have used nearly every day of my life, he induces old men and those loafing around in towns to get out into the garden and help "reduce the high cost of living." Now, this manufacturer could not have done any thing of the sort without having considerable capital. If he is a Christian man (and he certainly ought to be, and thank God there are lots of men of means who are Christians) he can easily be a personal friend, I might say, to every one in his employ, and to every one who buys one of his hoes. I might say the same thing about hammers. When Maydole first made a better hammer than the world had ever before seen, he sent out men to sell them. These men would drive a nail through a board, and then by means of the beautiful well-tempered claw, they would grab hold of the small end of the projecting nail and pull it through the board, head and all. My friends, you have probably tried to get along with a poor hammer, and I hope you have also found out what can be done with one of the very best Maydole hammers.

In the last few years it has got to be quite the fashion to put great values on special things.* Last summer the newspapers gave several accounts of women who have been robbed at fashionable watering-places. They carried along to these summer resorts diamond necklaces worth thousands of dollars. I am old-fashioned, I must confess; but I have reason to believe "there are others," and I have said several times to Mrs. Root, "What in the world does a woman want with a diamond necklace that cost enough to buy half a dozen good big farms? What good does it do them to invest money in that way?" And if the poor deluded creature in seeking for happiness must have the senseless bauble, why on earth should she carry it to a watering-place or have it in a Pullman car where the porter, who is perfectly innocent, may be worried to death because he is accused of stealing it? If Billy Sunday (may God be praised for what he has already done) or some other evangelist like him has been the means of getting such women—yes, and men too—to give up their diamonds, and "invest" the money in "treasures laid up in heaven," we can all rejoice that God's

* Just recently I noticed they are putting great value on special furs. I am told by the papers there are fox skins worth—no, I mean fox skins that are *called* worth—\$10,000; and if I am not mistaken I read of a pair of silver foxes that were sold for breeding purposes for \$60,000. These foxes that are worth such a pile of money are bred on Prince Edward Island, Canada. Can we not take it for granted that it is the women-folks who are mostly to blame for putting these tremendous values on a little piece of fur?

kingdom has come here on earth. Now, dear friends, let us get down home. Are you and am I, as we approach old age, seeking first the kingdom of God and his righteousness? Are you and I both making it our careful study every day to be laying up a little more treasure "where moth and rust doth not corrupt, and where thieves do not break through nor steal?"

WHEN LIFE LOOKS BLACK AND BLANK, WHAT SHALL WE DO?

Mr. Root:—I wrote you a few weeks ago inclosing an advertisement clipped from *Suburban Life*, telling of a new method of growing celery, etc. You also wrote me a personal letter upon receipt of mine, and it is for that letter I wish to write you now, thanking you for the way it was worded, for you finished the letter like this: "From your old friend A. I. Root."

When life looks as black to others as it does to me, a friendly word like that is as a glass of cool water to a thirsty man in the desert. I am glad I have an old friend. I wish I had some young friends too, and then they would not die so quick.

SELLING SECRETS: RIPENING TOMATOES UNDER GLASS, ETC.

I was tempted to send a dollar to another party who has a secret for the benefit of market-gardeners, and he wants a dollar for it. A party advertises in *GLEANINGS* that he has a method of ripening green tomatoes in November. He says, address with stamps. I sent him a stamp and asked for particulars. He wrote me he would mail the particulars for a dollar; but as it looks so much like the celery deal I will not send my hard-earned dollar.

W. G. BRAINARD.

Gouverneur, N. Y., Sept. 14.

Below is what I replied to the above:

Friend Brainard, is it not at least partly your fault that you don't have friends? Are you reading my talks through *GLEANINGS*? and are you reading your Bible and keeping in touch with Christian people? Are you going to church and Sunday-school? Are you trying to make the world better? Of course, I don't know your circumstances; but if you are interested in exploring God's gifts and high-pressure gardening, you ought to be thankful and happy.

Don't send any money for secrets. No good thing ever came in that way. I have taken the man to task in regard to green tomatoes, but he don't seem to want to let me have his secret, even if I offered to send him the dollar.

May the Holy Spirit help you to see what a precious gift is human life, and help us to see also that even the obstacles that lie across our pathway are often evidence of God's love if we take them in the right spirit. "Whom he loveth, he chasteneth."

I think I shall have to say a word more about the advertisement of a plan to have ripe tomatoes in November, etc. It was given in two issues of *GLEANINGS*—Aug. 15 and Sept. 1, as follows:

Have nice ripe tomatoes in November from your late green crop. Ripen without sunshine. Let me instruct you how. Address, with stamps, 520 Atwood St., Longmont, Colo.

The above reads as if the secret or the discovery would be sent on receipt of a couple of stamps or whatever the applicant saw fit to pay him for his trouble. It transpires, however, the advertiser (who

does not give his name, you will notice) wants the stamp to pay for sending his circular. This advertising circular tells you you can not have the secret without sending a dollar. Had we not supposed (as every one would suppose) that the instructions were given for the stamps, it would not have appeared in *GLEANINGS*; and this is to say that if any of our readers have been misled, and have sent a dollar in response to the advertisement, they can have their money back by letting us know. Our experiment stations have said repeatedly that no good thing in gardening or agriculture ever came by buying secrets. Perhaps I might add what is generally well known, that the great tomato industry in Florida is built up by gathering the tomatoes just before they begin to color. These are then wrapped up almost air-tight and shipped north. A plan was also given in *GLEANINGS* some years ago of pulling up the vines just before frost comes and spreading them out on straw in cold-frames under glass. The cold-frames are usually unoccupied at that season of the year, and the tomatoes ripen beautifully, and are sold at big prices in the North about Thanksgiving time.

A LEVEL-HEADED FARMER.

One of our people sent me the following clipping from some periodical:

I do not know when I have been so impressed by an item in a newspaper as I was by one I came across last night, while reading the exchanges that reach my desk. It appeared in a small county-seat paper published in a prominent grain-belt State, and was to this effect: "One farmer near — lost forty pigs during two days and one night. When sympathy was offered him over the financial disaster, the farmer said he felt thankful that such plagues stayed around the barn and did not enter the house."

While we honor and respect the good farmer for remembering, even during such a loss, that the loved ones in the home are of incomparably more value than the pigs, I want to say a word on another line. We do not know what State he lives in, but I believe that most of our States have experiment stations; and what are experiment stations for if not to help out farmers in just such calamities? Boiled ham (suitable for sandwiches) is now 40 cts. per lb. here in Medina, and 40 or more in Florida. Heading off the hog cholera by scientific means is protecting the poor hardworking people; and, if you will not accuse me of going to extremes, I should like to suggest it is also laying up treasures in heaven. If I am correctly informed (although I am not in the "pig business" but only a chicken man) our Department of Agriculture is getting the upper hand of just such troubles as are spoken of above.

High-pressure Gardening

"A CORN CATECHISM;" OR, IS IT POSSIBLE TO
RAISE 100 BUSHELS OR MORE OF CORN

PER ACRE UNDER OHIO CONDITIONS?

The above is the title of a very valuable bulletin of 16 pages, sent out by our Ohio State University. It gives directions, boiled down, for securing a good corn crop, that are exceedingly valuable. My impression is that the average farmer in the average locality can make 100 bushels per acre, without much question, if he follows directions.

The matter of barren cornstalks, which I considered in our last issue, is gone into quite thoroughly. To get this large yield one must have a perfect stand, or very near that. No hills should have less than three stalks, and none more than five. To do this you will have to do some thinning out. But I think this will pay in the end. Selecting your seed ears from the field in the fall is an important matter. Taking the corn out of the cornerib, as I have said, is a very poor way of improving your strain of corn. Two years ago I went through our cornfield and clipped off the stalks just above the ear for ears I wanted to save for seed. When husking time came we took four or five men out of the lumber-yard to do the husking. The man who was chosen as foreman, by my directions told the huskers to be very careful and save out the ears from the stalks that were clipped. What do you think happened? Most of the huskers were used to farmwork and husking corn; and in spite of orders all but the foreman paid no attention to the clipped stalks, thinking, probably, they knew more about picking seed corn than I did, and gave as an excuse that the proper way to get seed corn is to pick it out of the crib. Let me say again, your selected ears for planting should be taken from a hill of three or four stalks. Then you have your perfect ears in spite of environment. If a nice large ear is selected from the crib, the chances are great that it was taken from a hill containing only one stalk of corn. The ear was large and fine in this case because it had a better chance than the rest of the field, and not because of extra vitality and pedigree.

THE DASHEEN IN THE WEST INDIES; THE ORIGIN OF THE NAME, ETC.

Mr. Root:—I see by GLEANINGS that you and your readers are interesting yourselves in dasheen as a possible crop in the States. I grow this plant extensively as a "catch crop" between young cocoa trees, and wish to point out that the man who wants a crop (*i. e.*, tubers), puts in plants; and the man who wants plants put in tubers. Especially with

your short summer in Ohio it would be rather hopeless to expect a crop from tubers; but I quite understand that in Florida it might be different. As these plants thrive here with a rainfall of 100 inches a year they will naturally want more water than your annual rainfall gives them, and flat culture. I am sending you a dozen plants by parcel post, and want you to let me know in what condition they arrive. One plant is trimmed ready to plant; from the rest, remove all roots and dark root stock (put them in ground apart to make plants), and also skin away any discolored root sheath from plants, leaving a narrow line only of root stock for new roots to spring from.

Do you know how the word "dasheen" is derived? It was originally called in French patois "chou du chine" (shoo d'sheen), *i. e.*, the Chinaman's cabbage; but the *chou* has been dropped, and the English accent has altered the two last words to "dasheen."

GEO. S. HUDSON.

Errard Estate, St. Lucia, W. I., Aug. 19.

I must confess that I do not exactly understand about "tubers" and "plants," as mentioned above. The only thing we have any knowledge of so far is the tubers furnished by the Department of Agriculture, about the shape of an egg, only smaller, and these are what we planted. Perhaps the dasheen mentioned above is different from the Trinidad dasheen such as we have.

The sample "plants" so kindly furnished came to hand Sept. 17, just a little less than a month from the time they were mailed. So far as I can judge they stood the long trip finely, and came to hand with the white shoots already started, and an abundance of new white roots. In fact, they looked as if they had been growing on the way. I planted them out in good rich soil, and with the gentle shower that came right afterward I think every one of the dozen will grow. If frost comes I expect to protect them until we go back (Nov. 4) to our Florida home, when they will be moved again to our southern clime.

The name, "Chinese cabbage," may, perhaps, give us another clue to this considerable family of dasheens.

DASHEEN AT THE BATTLE CREEK SANITARIUM.

The following clipping appeared originally in *The Vegetable Grower* for Feb., 1913, and later appeared in *The Battle Creek Idea* for March 16. With it is a beautiful picture of dasheen sprouts in a greenhouse. It describes the efforts Dr. Kellogg is making for his patients.

Of course, it is necessary in a sanitarium that the food be as palatable as possible. Besides, it is the constant effort of Dr. J. H. Kellogg, the superintendent of the sanitarium, to provide as large a variety in the diet as possible. He has recently added to the menu a new vegetable, dasheen, which the United States Department of Agriculture is anxious to introduce into general use. The plant somewhat resembles the potato, and some people find it very palatable. The green shoots can be used like asparagus,

while the tubers can be served as potatoes or be ground into flour. The sanitarium has taken the entire product of dasheen of the Government Experiment Farm at Brooksville, Florida, last year. This amounts to more than a carload. It is planned to raise a considerable amount of this vegetable in the greenhouses for winter consumption. An experiment will also be made in growing it out of doors, the plants being started in the greenhouse.

Following this the *Idea* comments editorially:

The sanitarium, by the way, is harvesting its first crop of dasheen. The accompanying photograph shows the plants, beautifully blanched, and ready for the cutting. The stalks are cooked in much the same manner as asparagus, and are voted a remarkable success by the sanitarium guests. They have a delicate, individual flavor, unlike any other vegetable, though the root when baked is not at all unlike the Italian chestnut in flavor.

THE AMADUMBE, THE DASHEEN OF SOUTH AFRICA.

On page 471, July 1, a missionary of South Africa offered to send me some samples. See the following.

Mr. Root:—Your letter of June 3 arrived at Mount Silinda about two weeks ago, during my absence while attending the Rhodesia Missionary Conference at Bulawayo. I reached home yesterday.

I have put up a sample package containing three each of the malata sweet potatoes (as we call them), and the amadumbe, addressed to you. I will have it registered, and hope it will reach you safely. I am not quite sure as to the limit of weight of sample packages, so, instead of sending a larger package to Florida, I may send two packages in about two months or a little less, which should bring them to you in Florida in November. W. L. THOMPSON.

Mount Silinda, Melssetter, S. Rhodesia, Aug. 2.

The samples mentioned above are at hand. The amadumbe is so much like our Trinidad dasheen that it seems to me there can not be very much difference in form, shape, and solidity. The buds just started are exactly like the dasheen. We sent them all to our Florida home to be planted, with the exception of one bulb. I am going to plant this here in Medina to see how the foliage compares with the Trinidad dasheen. Many thanks, friend Thompson. When they get our parcel post in such shape that we can swap "garden sass" with the friends all over the world, including the remote islands of the sea, we shall no doubt be able to reduce the "high cost of living;" and spreading the gospel will help it along better than any thing else in the whole wide world. "Seek ye first the kingdom of God, and his righteousness," etc.

THE DASHEEN—SOMETHING DIRECT FROM THE ISLAND OF TRINIDAD.

Regarding dasheens, I may state that I confirm all that is written in *GLEANINGS* of Aug. 1, p. 553. The people here use it the same way. If they are higher than a man's head, as on p. 18, you are doing pretty well. We scarcely see them so high here. The tubers here attain 10 to 15 lbs. I do not agree with p. 18 of July 1 that it tastes better than the sweet potato—at least not to me. At the prices you are getting the bulbs there, I think it would not pay

you to send them from here by parcel post (the only way), paying 12 cts. per lb. postage. Otherwise I should be only too glad to send them. Besides, in a short time you are going to have them in large quantities, as the bulbs multiply so much; in fact, you have to be careful in the cultivation, otherwise what you get is only bulbs and no tubers. Unless you extract the bulbs continually you get no substance—tubers.

C. M. CARMONA.

San Rafael, Trinidad, B. W. I.

DASHEEN A SUCCESS IN OHIO.

To-day, Sept. 20, we made our first test of one of the side tubers of one of our dasheen plants. To my great surprise the tuber was bigger than a large hen's-egg; but as it was growing rank and thrifty there was a great green stalk (bigger than a hoe-handle) with large leaves on top. We cut off the largest leaves, then cut off the green stalk above the tuber, and cooked the green and the smaller leaves in a sort of stew. As there was considerable liquid in it when done I suggested putting in a few crackers; and it was one of my "happy surprises" to find it was so much like mushrooms that, had my eyes been shut, I should have declared it was mushrooms. The green tuber itself took nearly an hour to bake so as to be well done; and although it was not equal to the matured tuber sent me by the Department of Agriculture, it was what I would call a very nice baked potato—that is, when you bake potatoes that are only half ripe. Mrs. Root said at once the baked tubers tasted like a new potato not fully matured. Now, the maturity will depend on how long frost holds off. Sometimes here in our locality we do not have a killing frost till November. This would give us five or six weeks yet for the dasheen to ripen. From the fact that every bit of the plant is edible (and delicious food besides) I think it safe to say it may be grown as far north as we are.

May the Lord be praised for giving us this new vegetable for human food. The tuber I dug was from one of the side shoots. The central plant produces a very much larger one. The first large leaves on many of the plants have now turned yellow and are dying down. I take it that at maturity the leaves all die, and the nutriment in these great luscious leaves goes down to mature the tubers. The central stalks for quite a little distance above the ground are now as large around as the top of a teacup; and if they should be used now like asparagus there would be a large amount of nutritious food in them.

By the way, letters are coming in every day asking for tubers to plant. I can not furnish them. I expect to give the readers of *GLEANINGS* a tuber or two apiece. That is all I can do. Crenshaw Brothers, of

Tampa, Florida, are preparing to send seed tubers by parcel post. If you want a peck or a bushel or more I think you had better write to the Brooksville Development Co., Brooksville, Fla. That is where I got my five bushels.

Just one more word, dear friends. In writing up these articles on high-pressure gardening and developing God's gifts it would be out of place for me to have any thing to *sell*. There would be a temptation to exaggerate, and I should not feel free to commend or criticize as I do now; therefore please do not ask me to sell duck eggs, Buttercup eggs, dasheen tubers, or any thing I have mentioned here.

THE GUADA BEAN, OR SOLOMON'S ISLANDS GOURD.

We are pleased to notice in the Florida *Times-Union* a picture of the guada bean that I have several times spoken of. Below is what is said of them:

Mr. Davis has proved that these strange vegetables will grow in Florida, and of them he says, facetiously, in his paper, *The Winter Garden Times*, "Beans is beans. We now have on two vines of the guada bean or Solomon's Islands gourd, seventeen pods which measure from a foot to 44½ inches in length, which certainly strengthens our claim that 'Beans is beans.'

"We overcame our scruples Sunday, and cut three small ones that had curled up, and which we thought would not make good seed, and cooked them.

They were excellent, and remind one of the string bean or asparagus. We cooked in salted water; and with some creamery butter at 45 cents a pound, and pepper, they were good eating. It took about fifteen minutes to cook them tender.

"We have demonstrated that these beans could be grown in Florida during the hot summer months, and now we wish to try them for September, October, and November. We have two vines just coming through the ground; and if they mature in two months they might be ready for shipment in November. We expect to ship on a flat car and cord them up like cord wood. Nothing smaller than five-foot beans will be shipped."

I think it is now pretty well demonstrated that this bean can be grown in Ohio as well as in Florida; for notwithstanding the exceedingly cold and backward spring, and the further fact that we did not get the bean in time to plant early, we have now several pods big enough to cook. Very likely they will not grow long enough to be "corded up" as mentioned above; but if they are as good as asparagus they are certainly a great acquisition.

Later.—To-day, Sept. 17, our good friend Henry Boreher, of Laredo, Tex., has sent us a guada bean, by express, 30 inches long. We had a part of it for breakfast, and I should say it tasted like something half way between a summer squash and asparagus; and it is, without question, a very pleasant and nutritious food. I imagine it wants a good rich soil; but it promises to be quite an addition to our list of garden vegetables.

Temperance

Perhaps I should explain, before giving the following, that Akron, Ohio, is a big city with between 200 and 300 saloons. With this in mind, read the following from the *Ohio Messenger*:

DOUBLE STANDARD AT AKRON, OHIO.

Up at Akron, Ohio, the addle-pated men have licensed a lot of saloons to spread disease and degradation among the people.

The taxpayers make it a condition of conducting the infamous business that the saloonkeepers deliver over a part of the profits of the traffic.

In the nets thus spread, a lot of young people have been caught, and sent reeling toward the Pit. Many of these are young girls, lured into these traps designed by fool men for that purpose, and there their lives have been wrecked.

It appears that since January 1 twenty-four men have pleaded guilty to or have been convicted of contributing to the delinquency of young girls. The saloon was the chief instrument through which these vipers operated.

Out of the twenty-four, only seven are undergoing punishment. The others are under suspended sentences in whole or in part, or are running around on bond.

Swift punishment was the invariable fate of the girls.

The women of Akron are up in arms at this, and demand the punishment of the men along with the women.

But justice in Akron wears pants; and, being a

part of the electorate, it shares in the miserable guilt. It is part of the body politic that votes to license the business, and then goes around snivelling about the natural, unerring results.

If the women could make any worse mess of things than the men have done, if given the ballot, then popular government is, indeed, in a sorry plight.

"SOMETHING'S THE MATTER WITH KANSAS."

We make the following extract from an article in the *American Advance* for Sept. 6, copied from the Philadelphia *North American*.

A few days ago, when the whole country was worrying about the unprecedented heat and drouth in the West, the governor of Kansas issued a public statement saying he hoped no one would waste pity on the people of his State.

"With more than \$200,000,000 on deposit in our State and National banks, we could weather a worse storm than this without hardship," he said.

And when you stop to think that this money, divided equally among the men, women, children, and babies of Kansas, would give each of them \$118 in cash, not to mention the tidy sum of \$1684 each is credited with as his or her share of the State's assessed wealth, you can see the force of the argument.

As a matter of fact, Kansas, which last year produced \$325,000,000 worth of farm products, can better afford such a roasting and drying up than any other State in the Union, for her per capita wealth is larger than that of any other State.

She can better afford this or any brand of calamity, for her people are not constantly paying out huge sums for the care and keep of criminals, paupers, insane, and feeble-minded.

In eighty-seven of her 105 counties there are no insane. In fifty-four of this number are no feeble-minded. Ninety-six counties have no inebriates, and in the other nine they're as scarce as hens' teeth. Thirty-eight county poorhouses are as empty as a last year's locust shell, and most of these have been so for the best part of a decade.

At one time not long ago the jails in fifty-three counties were empty, and sixty-five counties were on the roll as having no prisoners serving sentence in the penitentiary. Some counties have not called a jury to try a criminal case in ten years, and the attorney-general says, "A grand jury is so uncommon that half our people wouldn't know what it is and how to use it."

Something is the matter with her. That something, we believe, can be boiled down into these first fourteen words constituting an amendment made to her constitution in 1881:

"The manufacture and sale of intoxicating liquor shall be for ever prohibited in this State."

Something similar has appeared in GLEANINGS already, but without the further details. When you hear people talking about our government losing "revenue" by banishing the saloon, point them to the above facts in regard to Kansas.

SOME GOOD NEWS FROM AN OLD FRIEND AWAY OFF IN CALIFORNIA.

Mr. Root:—We just had a conversation at our breakfast table; and wondering if it would not please you we mail you a clipping from our daily paper, the *San Bernardino Sun*, in regard to the great victory of prohibition, as you will see it was sweeping in character. The ladies began marching to the polls early, and kept it up until late; hence the large majority. The Salvation Army workers are doing a wonderful lot of good in their open way of worship and sign-posting. At public watering-troughs along the highways, and on smooth-faced stones some scripture texts are inscribed, and under advertisements of social gatherings, races, etc.

Rialto, Cal., Sept. 10. E. J. ATCHLEY.

Below is the clipping referred to:

RIALTO DRY IN REALITY; BOOZE-WAGONS CAN NO MORE DELIVER GOODS TO THE CITRUS CENTER.

By a decisive vote last Saturday Rialto not only put a ban on saloons; but the delivery wagons which heretofore have been delivering wet goods from adjoining towns and cities will be a thing of the past.

It was a great victory for the "drys," the vote being 185 for the banishment of the wet goods to 42 which favored.

The real intent of the election was for the purpose of putting a stop to the delivery of intoxicants from cities where liquor licenses are in vogue.

The result of the election also prohibits liquor from being given away in Rialto. Sentiment against the legalizing or assisting in the use of liquor in any way was overwhelming in the pretty little city of Rialto, and intense interest was taken in the election, by both sides.

Please notice the overwhelming victory in the above was brought about by the women, the Salvation Army, and everybody else; and the suggestion in regard to putting up temperance mottoes and scripture texts, etc., is well worthy of being followed. We might

indeed call it "high-pressure" temperance work. Who comes next?

THE ANTI-CIGARETTE LAW OF WEST VIRGINIA.

Dear Mr. Root:—I am sending a copy of the cigarette law of our State, which I know will interest you. I saw where you had been informed of our State going dry. I hope you will live to see this same law go into effect in every State, and I believe you will.

MRS. CONRAD G. ANDERSON.

Yellow Springs, W. Va., Aug. 2.

Amen to the wish that a similar or more sweeping law may be enacted for every State. Below is the clipping referred to:

Prosecuting Attorney Robert White has requested the *Review* to publish the cigarette law, which goes into effect May 24, which will be done later.

In this statute it is unlawful to sell, offer, or expose for sale, or give away or furnish or cause to be given away or furnished to any person under the age of twenty-one any cigarette or cigarette papers; and it is unlawful to sell or give to any person under the age of sixteen years any cigar, pipe, or tobacco in any form. It is also unlawful for any person under the age of twenty-one years to smoke or have in his possession any cigarette or cigarette papers. For each offense there is a fine of \$5.00.

The Prosecuting Attorney desires attention called especially to the fact that every constable, policeman, town sergeant, sheriff, or his deputy, when he finds any person violating the provisions of this act shall make inquiries and arrest such person at once. And if any such officer fails to perform this duty required of him he shall be fined \$5.00. A fine of \$5.00 is the penalty for smoking or using cigarettes in any school building or on lands used for school purposes.

IMPROVED PARCEL POST; SOME SUGGESTIONS BY OUR GOOD FRIEND A. T. COOK.

Much praise is due Postmaster-General Burleson for his improving our parcel post. More may be mentioned.

All third-class matter should be included, and the rate for all matter under one pound for any distance be 1 cent per 2 ounces or pound rate. This would entirely eliminate the third class, and wonderfully simplify the business. Surely third-class matter—seeds, plants, books, etc., deserve as low a rate as any. (Before the parcel post they were but half the merchandise rate.) As parcel post now stands, 1 cent per ounce up to 4 ounces is too high, and no better than old rates; and over 4 ounces, much higher than before, in many cases even more than letter postage. This should be changed quickly.

I think too the "zones" could be simplified, and three zones be a plenty; viz.: First zone, the county and all adjacent counties; second zone, the States and all adjacent States; third zone, everything beyond. Of course local rural routes should have their special rates.

A. T. COOK.

Hyde Park, N. Y., Aug. 6.

WHAT ONE OF OUR ADVERTISERS THINKS OF THE VALUE OF OUR ADVERTISING COLUMNS.

The A. I. Root Co.:—Inclosed find check for balance due on my advertisement. You may discontinue the same. I will be ready for another in the spring. I am glad to say that I did a nice business this season, and I believe my customers are all satisfied, as I tried to treat them right. I have lost but three or four queens on the road. I certainly feel that the advertisement did me lots of good, as nearly all said they saw it in GLEANINGS. I have not had one complaint all summer.

NO. 20

Editorial

THE EDITOR OF THE AMERICAN BEE JOURNAL
ABROAD.

THE editor of the *American Bee Journal*, who has been traveling in Europe, writes entertainingly in his paper about his trip. Mr. Dadant has not only been going through his fatherland, France, but through Italy and Switzerland.

DEATH OF MR. JACOB HUFFMAN.

MR. JACOB HUFFMAN, of Monroe, Wis., died recently of a paralytic stroke. He was for a number of years president of the Wisconsin State Beekeepers' Association, and at one time was vice-president of the National Beekeepers' Association. He seldom wrote for the bee journals, but was prominent at conventions. He was one of the most extensive as well as one of the best beekeepers of his State. He will be missed by his fellow craftsmen.

NOTICES OF NEW BULLETINS ON BEES.

It is always our intention to make editorial mention of any new book or bulletin on bees. If we inadvertently omit such mention, the author or parties concerned will confer a favor by calling our attention to it, at the same time seeing to it that another bulletin is sent. It is not always possible for us to keep track of works published in foreign countries, and especially those printed in other languages. The conditions of management and climate necessarily render a work in another country of little value elsewhere. The A B C and X Y Z of Bee Culture, however, aims to be cosmopolitan as far as the United States and Canada are concerned. In this country we have nearly all conditions of climate that are found in other parts of the world; and our work is, therefore, adapted to all climates where bees are kept.

WHY, TO BE SURE.

THE new State Chemist in Idaho is a man who takes a pretty practical view of things if we may judge by his statement in regard to the belief that so much honey is adulterated. We quote herewith the paragraph in

question from the *Evening Capital News*, of Boise, Idaho:

"I wonder why it is that people believe honey has been adulterated, even though they have seen the farmer gather it when they buy," asks the State Chemist. "They don't act the same way when they buy other things on the market. If they should get a can of maple syrup that was largely adulterated, the first question they would ask is, 'Well, it won't hurt me will it?'"

Too many people are all too willing to believe that foods of all kinds are adulterated. They like to say that maple syrup is made out of glucose and corncobs, etc. Personally we like to think that what we are eating is clean, and that it came from clean surroundings. That is why we like to eat honey.

NEW YORK STATE BULLETIN NO. 49, ON THE
SUBJECT OF THE HONEYBEE, BY W. D.
WRIGHT, FREE TO ALL.

IN our issue for September 15 we gave an extended review of a bulletin issued by the Department of Agriculture at Albany, N. Y. It will be remembered that we spoke of it as one of the best specimens of the printer's art that has ever been published, and that it was written by one of the best beekeepers in the Empire State. We suggested that all outside of New York might have to pay 10 or 25 cents for it. Commissioner Huson says they are free to all. Here is what he says:

Mr. Root:—We wish to thank you for the very pleasant notice that you gave in GLEANINGS for September 15 relative to our recent bulletin No. 49 on the subject of the honeybee. We notice that you suggested that these bulletins could be sent outside of the State of New York on payment of a fee of ten or twenty-five cents. It is my desire to supply these bulletins free of cost to any persons who are interested in the subject as long as we have an available supply for the purpose.

CALVIN J. HUSON, Commissioner.

Albany, N. Y., Oct. 1.

It is a splendid book, and is well worth reading, and keeping in any library, especially when it costs no more than a postal card to get it. Now is your chance, brother beekeepers; but do it "fust," as David Harum says, as the edition may be exhausted.

A REVISION OF "WINTERING BEES."

WE have just received from the GLEANINGS press a newly revised edition of a book entitled "Wintering Bees," by E. R. Root. It contains 62 pages, paper covered. It is fully illustrated, and well printed. This new revised edition contains particulars regarding the latest methods of wintering, such as the subject of candy for feeding bees. It also places strong emphasis on the importance of windbreaks for outside colonies. In a general way it covers the whole subject of indoor and outdoor wintering; ventilation and temperature of bee-cellars; general construction of bee-cellars; then winds up with a few concluding facts well to bear in mind. These facts or statements were indorsed by no less authorities than Dr. C. C. Miller and the late W. Z. Hutchinson. Price 10 cents, postpaid.

CORRECTION REGARDING MILLER METHOD OF INTRODUCING.

THE following telegram from Mr. Arthur C. Miller, just as we go to press, will explain:

E. R. Root:—You have misquoted me, and thereby done me injustice—editorial, page 667. I do not confine queens twelve hours. Alley did not introduce to full colonies with tobacco smoke—Handy book, pages 25 and 26, edition 1883.

ARTHUR C. MILLER.

Providence, R. I., Oct. 10.

We do not know how this error crept in; but the method that we find so efficacious is precisely the one that Mr. Miller recommended in his article on page 370 in our issue for June 1. Furthermore, it is true that Mr. Alley did not introduce to full colonies. The only point of similarity between the Alley method and the Miller is that Alley used tobacco smoke and introduced only to nuclei. He evidently did not contemplate the plan of introducing to full colonies, under all conditions, laying and virgin queens, the latter of any age. We may say further that we are still using the plan; and if it continues to work as satisfactorily as it has done, we shall recommend it to all of our customers in preference to the caging method.

ARE SPECIAL NUMBERS ON ONE TOPIC CONFUSING?

OUR first idea in providing special numbers such as we have had during the last few years was to draw out the best available thought on the special subject in question, so that in a "multitude of counselors" there might be wisdom. In one, or two of these numbers, experts have disagreed somewhat, so that we were fearful the effect might be somewhat confusing. This fear is expressed by one of our subscribers, Rev.

G. H. Chatterton, who writes as follows: "For my part I do not care so much to have one whole number on one subject. It seems to confuse one when there are so many different views expressed."

We are willing to abide by the wishes of our readers in this respect. We shall soon have to be making plans for the special numbers next year if we have them, and at this time, therefore, we should be very glad if those of our readers who are interested in the matter would express their opinion briefly on a postcard, and mail it to us. We should prefer to have nothing else on the card, and to have the opinion on a postcard only. We shall govern our actions according to the opinions expressed by the majority of those who vote.

GETTING COMBS FASTENED IN SECTIONS AFTER THEY HAVE BEEN FILLED WITH HONEY AND CAPPED OVER.

DR. A. F. BONNEY, after seeing the article by Dr. Humpert in our last issue, page 674, on cutting up filled extracting-combs and fitting them into sections for the bees to fasten, wrote us that he had been experimenting along the same general lines without the knowledge of what our correspondent had been doing, and that, before he had seen the Humpert article, he had sent a communication to the *American Bee Journal* that is yet to be published. He hoped, therefore, no one would think he had been copying.

In the mean time, A. I. Root says that away back in the early '70's the first section honey he ever put up was made in this way—that is to say, he cut up the best combs from his extracting-frames, and fitted them into squares of wood for the bees to fasten afterward. These he called "sections" or "sectional honey-boxes." If we are correct, he originated these names. Well, he made the discovery that the bees would not make the attachments satisfactorily in most cases—that it was very much better to put the sections in the hive, let the bees build, fill, and cap the combs in the first place, than it was to work on the other plan.

In relation to this matter, we have received a letter from Mr. M. H. Hunt, one of the veteran beekeepers of Michigan, and who did a good deal of pioneer work among his bees when A. I. Root was doing his early experimenting. Mr. Hunt writes:

Dear Mr. Root:—I have just finished reading Dr. G. A. Humpert's article in Oct. 1st GLEANINGS. Years ago, when I used to go to fairs, I cut honey to fit solidly into glass and wooden sections, and had the bees fasten the same. This summer I had only two days' notice of a banquet, and I cut and

fitted into sections $2\frac{1}{2} \times 2$ enough for each one in attendance. I have always found that a large percentage of the sections so fixed will fail to be anywhere near perfect. The larger the section the greater the success.

Redford, Mich., Oct. 8.

M. H. HUNT.

As stated in our issue for Oct. 1, the plan of cutting up combs into small squares out of extracting-frames is feasible; but such combs should be allowed to drain, then wrapped in paraffine paper, and put into cartons. A. I. Root is very positive that it is not practicable to have these cut combs, after they have been capped over, fitted into and fastened into sections by the bees as an after-operation. While they *may* make a few individual specimens that will look very well, in a large way he says the plan is not a success.

OUR COVER DESIGN; CELL-BUILDING COLONIES.

OUR front cover design for Sept. 15th issue shows a view of our queen-mating baby nuclei among the basswoods where we raised and mated over 3000 queens during the past season. On the cover of this issue we show the cell-building colonies for these same babies a little further along in the same grove. Not all the hives are cell-builders, but all the two-story are devoted (or were at the time the picture was taken) to that purpose, and all of them were operated for honey. Last year was an exceptional one for nectar secretion. It was not necessary, therefore, to feed these cell-builders—in fact, our Mr. Pritchard was greatly embarrassed by such a flood of honey coming in that his queens were honey-bound, and his cell-builders swarmed and swarmed and swarmed, keeping him busy a great deal of the time in shinning up trees, for these powerful colonies devoted to building cells would of course be in fine condition to swarm. The usual procedure of cutting out cells would not do, for that would defeat the very purpose of these colonies, so Mr. Pritchard had to grin and bear it. Once or twice he was compelled to witness one or two of his crack colonies sail over the tops of the basswoods and fly on and on and on, crosslots, for parts unknown.

This is a very good location among the basswoods; and, as will be seen, it is well sheltered in all directions from the prevailing winds. The only exposure is toward the south, and we seldom fear a south wind, even in mid-winter. Next to this basswood grove on the north is a dense growth of woods. On the west is an extension of the grove for about one thousand feet further on. During the windiest of days there will be no piercing blast to interfere with wintering or springing.

On the other side of the building is a

driven well which is out of view. It supplies us with plenty of clean water for washing, and for making up syrup whenever there is no honey coming in; for it should be understood that cell-builders should be kept in a highly prosperous condition by slow feeding if there is no honey coming in from the fields. We use a Boardman entrance feeder with glass Mason jars, some of which will be seen in the foreground. The syrup is received through three or four holes in the cap, and the supply is so restricted that a filled can of syrup will last even a cell-builder 48 or more hours. As long as there is a constant supply of food coming in, the work on the cells will continue uninterruptedly. But if one of these feeders, by chance or otherwise, should be allowed to remain empty for a few hours during a dearth of honey, there will be danger that every cell will be destroyed.

For further particulars regarding this basswood yard and its early history, see page 631, Sept. 15th issue.

NATURAL VS. ARTIFICIAL RIPENING OF HONEY.

WHILE we doubt whether it will pay to utilize any more space in GLEANINGS for a discussion of artificial ripening of honey, since the great bulk of the evidence is against the practice, we should like to mention, nevertheless, that in the May 15th issue of the *Australian Beekeeper* a discussion on the subject appears, which is really a symposium. As usual there is a difference in opinion, although there is not such a feeling against the practice in Australia, apparently, as in this country for instance. We desire to point out in passing that at least one of the writers is laboring under a misapprehension when he believes that the bees do nothing to the nectar of the flowers except to evaporate the excess of moisture—in other words, that the ripening process is merely driving off the excess of water. All chemists know that there is a decided chemical difference between the sugar found in the nectar of the flowers and that in ripened honey. By the time the evaporation is accomplished by the bees, the “inversion,” as it is technically called, has been brought about.

While not recommending the practice we believe that there are localities where it is safe for a judicious beekeeper to extract from combs not yet capped over. We believe, also, that in many other localities there are certain combinations of conditions of weather, atmosphere, etc., where the honey is entirely ripe before it is capped over. As an illustration, because of the necessity of providing room for colonies in one of our

yards during the height of a period of excessive swarming, we extracted something over a thousand pounds from combs, many of which were not yet even partly sealed. To our surprise the honey was as thick as any we ever extracted, and the flavor was also equal to the very best. Under other conditions (this was toward the close of quite a protracted drouth) we are sure that the honey would have been thin and entirely unfit for table use.

We wish to go on record, as we have said before, that we do not believe in extracting *green* honey, and then making an effort to ripen it artificially. With a suitable equipment we believe an expert may succeed; but we can not recommend the practice for the average beekeeper under the average conditions.

WHY THERE WAS NO APPROPRIATION FOR THE TEXAS FOUL-BROOD LAW.

In our issue for Oct. 1 we referred to the fact that the splendid foul-brood law that was enacted by the last legislature of Texas did not carry with it an appropriation to put it into effect. In writing to State Entomologist Wilmon Newell concerning it we stated that the situation was somewhat the same in his State as it was formerly in Pennsylvania; and we suggested that perhaps under the circumstances Mr. Newell could adopt the same scheme that was employed two years ago in Pennsylvania—namely, secure volunteer service from beekeepers interested in the suppression of foul brood in their respective localities. Much good was done in Pennsylvania because Prof. H. A. Surface, State Entomologist, clothed these volunteer inspectors with police authority. The result was, a large amount of good was done. In referring to this, Mr. Newell writes, under date of Sept. 23; and as this letter plainly states *why* this appropriation was not obtained, we have secured his permission to publish it, and here it is:

Dear Mr. Root:—Replying to yours of the 16th, our situation is quite different from what Prof. Surface had to contend with in Pennsylvania. He did have an appropriation of \$500 with which to meet "overhead expenses," I understand, whereas we have *nothing*. A system of volunteer inspectors would involve a pretty heavy correspondence for this office, and this we can hardly undertake with no money with which to defray postage, stationery, stenographic expenses, etc. What is more, now that no appropriation has been made for foul-brood eradication, I am not officially supposed to have that work on my hands, and my time is fully taken up with other lines of work. What I have done, however, is to notify the county associations that in all cases where they will defray the expenses of the inspector (the amount of the inspector's compensation to be arranged between the association and the inspector) we will furnish the inspector with an official appointment, and the necessary authority for the work.

As a matter of fact, our Texas inspectors have in the past been little more than volunteers. They have been paid at the rate of \$3.00 per day for time actually employed, and out of this have paid their own local traveling expenses and furnished their own conveyances. They were really giving their time to the State, and breaking even on the cash outlay involved.

I may add that the beekeepers of the State evidently did not strain themselves any to see that the appropriation was renewed. So far as I can learn, only one beekeeper took the trouble to visit Austin for this purpose while the last legislature was in session. If the men whose property is at stake have no more interest in the eradication of bee diseases than this, why should I work nights and holidays, and go to Austin and lobby for foul-brood appropriations at my own expense? I have never received a cent of salary for the time and work devoted to foul-brood eradication. The only satisfaction I have is that of *knowing* that nearly a thousand cases of disease have been cleaned up, and that half a million dollars invested in beekeeping has received protection from disease during the past four years.

Now that things have turned out as they have, I rather regret the last sentence of the article in GLEANINGS, which states that copies of the new foul-brood law were ready for distribution about Sept. 15. Now that there is no appropriation we can not, of course, print any copies of the foul-brood law, and the immense amount of work in other lines absolutely precludes our taking the time to either type-write or multigraph a sufficient supply to meet all requests.

WILMON NEWELL.

College Station, Tex., Sept. 23.

Not only the beekeepers of Texas, but all other beekeepers in the Union, should read this letter. It has happened more than once that apathy on the part of beekeepers has been responsible for the defeat of suitable foul-brood legislation. Law-makers will very often disregard the request of a single individual, even though he be a State official; but if this same official is backed up by a State organization representing a large membership, or if, however, the beekeepers present themselves in a body before the legislative committee having the bill in charge, as a general thing something will be done. We can not blame the legislators for failing to enact laws when the parties most interested in a financial way or otherwise do not show any interest in the measure. If the beekeepers of Texas had sent in a thousand or more postals to the members of their general assembly, the situation would not be as it is now.

Referring to the \$500 appropriation available to Professor Surface for foul-brood inspection work, we may state that two years ago he had no appropriation. Having the law, he was able to enlist the services of quite a number of volunteer inspectors whom he clothed with police authority. During the past year he was able to get \$1000 for two years instead of \$3500 for one year. He made the first \$500 go as far as he could. He may have to depend largely on the volunteer inspection work as before.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

R. F. HOLTERMANN, you wonder, p. 651, why the capacity of smokers for fuel is not greater, so as to save more time. The answer to that is easy, friend H. It's because we're not all great big fellows like you, with strength to burn. I'd rather waste time to load up two or three more times in a day than to waste a good deal more in the way of strength by lugging around too heavy a smoker. The chief objection to the average smoker "in this locality" is that it wastes strength by having the spring unnecessarily stiff. We'll let you get big smokers to save your time, if you'll let us save our strength.

THAT talk, p. 660, about selecting the right seed to improve the corn crop, thus adding thousands to the general wealth, is capital. And it forms a fine text for the improvement of bees. If every beekeeper in the land would take as much pains in selecting the right stock to breed his bees from as A. I. Root advises about corn, it might easily increase the total of honey 25 per cent, and that without increasing the labor of beekeepers. I think it would be a gain to beekeepers, and I know it would be a gain to the consuming public. And there's another thing I know, and it's this: That so long as the great mass of beekeepers are so listless about it, the few who do make a business of improving stock will gain by it—*big*.

A ROADSIDE WEED OF WORTH is the caption of an item in *The Country Gentleman*, in which the editor says: "Farmers are learning that fields too dry, too stony, too hard to grow any thing else, will become green and valuable with sweet clover; and they are learning that stock relish it as much as alfalfa. [Yes, and the farmers of the semi-arid West, in parts of Kansas and Nebraska, are discovering that their uplands that are too hard and too dry to grow alfalfa will grow sweet clover luxuriantly. Pigs and other kinds of stock are now being well fed on these same kinds of waste lands. The time is coming when the Eastern farmer as well as the Western rancher will grow sweet clover on certain of his lands as he now does corn, grass, and other clovers on good land.—ED.]

RAISING hives on 7/8-inch blocks is a help toward the prevention of swarming, but in this locality it is by no means so effective as described on page 593. I practiced it on a large scale years ago, but had to cut cells all the same, and at that had a good deal more than three per cent of swarms. [Locality *may* make a difference. Mr. Vernon

Burt is a very successful beekeeper, and conservative in his statements. We are sure the plan works with him. Possibly the strain of bees may have something to do with it. While *you* have been breeding toward non-swarmer, Mr. Burt has given his attention largely to honey-producers. We shall be glad to get reports from others in regard to the success or failure of this scheme of putting hives up on four blocks. Almost any plan will work successfully during a poor season; but when honey comes in with a rush, preceded by a gentle flow, just enough to start brood-rearing at a good pace, it is not always easy to control swarming by orthodox methods.—ED.]

"THERE is absolutely no harm in saying in one's advertisement, 'I have the finest queens ever produced.' Such a statement is a general one, and can be accepted as such when summing up," p. 607. But if the advertisement reads, "My bees are all free from foul brood," then the advertising manager must demand proof. Wouldn't that make it a little hard for both the manager and the advertiser? But saying nothing about that, the whole tenor of the thing sounds a good deal like saying, "There is absolutely no harm in lying in general, but you must be careful about lying in particular." If two different advertisers say, "I have the finest queens ever produced," one or the other must be lying. Indeed, I can not conceive how any one can truthfully say, "I have the finest queens ever produced" unless he has actual knowledge of all queens ever produced, and who has that knowledge? The fact is, and it is a lamentable fact, that one does not expect the exact truth in advertisements. A lie is a lie, whether general or particular, in an advertisement as well as elsewhere. It is gratifying to know that at a late meeting of the national association of advertising men, "Truth" was adopted as their motto. Let's have the truth, both in particular and in general. [We sometimes say a horse goes by "like lightning;" and the same kind of hyperbole seems to have crept into much of present-day advertising; but the time has come now when an exact and honest statement without exaggeration will bring in larger returns of money than boastful advertising that tries to make the buying public believe what it knows is not true.—ED.]

FRANK A. GRAY asks how to pack a section or more of honey for parcel post. Doubtful if comb honey can yet be sent by

parcel post. If a single section is sent, it might be in a light box with corrugated paper around it. For a larger package use a safety shipping case, and I don't know whether it would be safer to have extra corrugated paper around the case, or to send without, so the honey can be seen through the glass. [As we have said several times before in these columns, we repeat again, we hope that, for the present at least, beekeepers will not commit the folly of attempting to send comb or extracted honey by parcel post. The disastrous experiences of those who have tried it will, we fear, so prejudice the postal authorities that they will never allow honey to be shipped in that way. We believe it can be done some time in the future; but we ought not to make the fearful mistake of prejudicing our chances for all time by making the attempt now. Nothing can disgust the general public more, and the postal authorities as well, than to have their parcels daubed with honey. For pity's sake, brother beekeepers, do not try it. Parcel post is on trial to a certain extent. While we believe it has come to stay, we should give the system a fair test, and that means, not to attempt the impossible until suitable regulations have been made whereby honey and other fragile articles can be given a classification and handling by themselves. Just now, for example, the women of Cleveland are sending paving bricks by parcel post to the man who has charge of the streets of Cleveland to stir him up to the need of repairs. If one of the "pavers" is put in a sack with a section of honey there is going to be a mess as sure as fate. See editorial column.—ED.]

THAT item from the *Farm Journal*, p. 629, is fine, except where it makes too strong a claim for honey. Aside from any moral question, there's no gain in the long run by going beyond the strict truth. I wonder what is the average dryness of honey. Is it, as claimed, *usually* "less than 20 per cent of water"? I don't know about that, but I do know that another claim is away off which says, "Honey will keep indefinitely. . . . Actually, honey improves with age." I kept a sample of beautiful white extracted honey until it was as black as molasses, and utterly spoiled with age. Would any one claim he ought to get a better price for his honey because it is a year old? There are enough good things about honey that we ought to teach the public. Please don't let's get in the way of lying about it. [By consulting Bulletin No. 110, from the Bureau of Chemistry, United States Department of Agriculture, by

Brown, you will find the average analysis of honey as follows:

Moisture	17.70	per cent
Levulose	40.50	per cent
Dextrose	34.02	per cent
Sucrose	1.90	per cent
Ash	0.18	per cent
Dextrin	1.51	per cent
Undetermined	4.19	per cent
	100.00	per cent

It will be seen from this statement that less than 20 per cent of water is correct, for Brown is known to be one of the best chemists in the United States.

About honey keeping "indefinitely" and improving with age, suppose you look at the September issue of the *National Geographical Magazine*, p. 999. On that page you will see where some findings from one of the pyramids of Egypt are illustrated and described. Among other things we read:

FRESH HONEY 3300 YEARS OLD.

Most startling of all was the discovery of a jar of honey, still liquid, and still preserving its characteristic scent after 3300 years! "One looked," said Mr. Weigall, "from one article to another with the feeling that the entire human conception of time is wrong. These were the things of yesterday, of a year or two ago."

If we are correct, there is another account of honey being found in the pyramids, and it was in excellent condition. We positively know this: We have tasted extracted honey that was twelve years old. Some very interesting data on this subject will be found on pages 712 and 713 in this issue by R. C. Aikin.

Referring to the sample that you kept until it was "as black as molasses," the question all hinges on *how* you "kept" it. Honey should be kept in a dry *dark* place. Conditions inside of the pyramid, as we understand it, were ideal for the preservation of human bodies, of monkeys, of dogs, and of cats, which were also mummified. If that were so, why would not honey keep under conditions which were perfect—possibly more so than we can supply in this country?

Is it not true that good extracted honey will improve with age up to a certain point when conditions are right? Honey that has not been thoroughly ripened will improve very much if kept in open vats in a dry atmosphere. Even comb honey, up to six months or a year old, will have a richer and mellower flavor providing it does not granulate. Perhaps it is too startling for the average mind to conceive of a honey 3300 years old, "still liquid," and still preserving its "characteristic scent." But is there another food in the world, of a semi-liquid character, that will keep as long?—ED.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

One of the neatest yards of bees I have seen this season was one where a few sheep were kept, and no lawn could be more free from grass and weeds. I don't believe the use of sheep for this purpose has been half appreciated.

* * *

Mr. Chadwick's estimate of the income that could be expected from a yard of bees as an investment in the hands of a fairly good beekeeper, page 441, would be a fair estimate in this part of the world, but the difficulty would be to find the reliable beekeeper.

* * *

I know of no business that is carried on with so little actual knowledge of it as beekeeping by the average beekeeper. He knows that bees need a hive; that they swarm, make honey, and are made angry by sweaty horses. Well, some of them are learning these days that bees have diseases, like other animal life, to their sorrow.

* * *

Friend Byer, on page 438, discusses the quality of Southern honey. Now, I know it is a sure thing that they produce some fine honey in the South, for I have eaten it right out of the hive in Florida, and found some the equal of our best Northern honey. And I have eaten it on the table of my friend J. J. Wilder, in Georgia, and I know it was good; but it is not all so.

* * *

If you buy comb-frames ready made, and holes in end-bars already punched, you are ready for wiring; but if you make them yourself, the punching of holes in the end pieces is quite an item. But some one has told me this season that using a thin saw and cutting a slot down half way through the end-bars, where the wires are wanted, is quicker than punching holes; and then the wiring is simplicity itself, for you only have to place the wire in the slots without the bother of running it through holes at each end. This cutting or sawing into the end-bars might seem to weaken them; but in time the bees will soon fill the slots with propolis, and make them all right.

* * *

A recent number of the *Technical World* tells of an invention to attach to a hive, a sort of speedometer that will register the number of bees leaving or entering a hive during the day. This would, if it proves practical, solve several interesting problems that we have been heretofore unable

to unders'and perfectly, as, How many bees does it take when gathering honey freely to gather a pound? How many bees go out each day, and how many return? How many more are lost on windy days than on those days that are pleasant? How many more bees does it take to gather a pound of honey during seasons of comparative scarcity than when the flowers are rich in nectar?

* * *

On page 437 Dr. Miller refers to compensation to those whose foul-broody colonies are destroyed. A bee inspector has often to meet this inquiry: "Does the State pay for the loss?" The State certainly ought *not* to be held responsible for the loss caused by the bees being diseased; and if the State sends a man, paying for his time and expenses, to show to the owner of a lot of bees their condition, and instructs him how to get rid of disease, it would seem that the responsibility of the State would cease. If the owner of a lot of diseased bees refuses to clean them up after he is told how, but leaves them to spread contagion all around him, he is entitled to little sympathy, whether the inspector destroys them or they are left to die without "medical assistance."

* * *

My dear Mr. Riebel, my sympathies are with you as you relate on pages 445, 446, the condition you find honey in stores. Oh, my! but doesn't one want to shake up both the slovenly beekeeper and ignorant grocer, and give them both a piece of his mind? As I go around among beekeepers my astonishment at their ignorance and folly never ceases. I find hives with supers resting directly on the frames, and glued down solidly with propolis, or perhaps an inch space between them, or perhaps a super without sections, or bottom with combs built from the top of the super to the top of the hive, or combs running at every angle to the top-bar of frames, or, perchance, a whole yard without a super on, or scarcely a chance to put one on, or supers without separators, and the combs built to suit the whims of the bees. Oh, dear! How can such be made to see their folly, and make them realize that they are losing dollars to save cents? They won't take a journal—no, no; they can not afford it. *Gleanings* for July 1 is worth all the journal costs for ten years just for the information it gives along the line of marketing honey; but, alas! they can not see it.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

A correspondent speaks of a bee-tree that contained a million bees and a barrel of honey. I guess a million bees could gather a barrel of honey all right. Some bees, though.

* * *

The Miller plan of introducing queens seems to be standing the test wherever it is tried, but I will stake my reputation that there are certain conditions under which this plan will also fail. In a recent issue of the *Western Honey Bee*, Mr. J. D. Bixby recommends the use of tobacco smoke when introducing direct.

* * *

I read a report in our local paper that the office of bee inspector is to be discontinued for the present. I am inclined to believe that it is only a report, and is not being seriously considered. The office of bee inspector was created by a State law, and it is difficult for me to understand how a county board of supervisors could suspend its action. We have been getting much needed work from our inspector, M. J. Meeker. I say needed work, for it has been many years since we have had a man in the office who has taken hold with energy. Mr. Meeker has done much effective work in the few months he has been in office.

* * *

In regard to the cutting of alfalfa for hay, I think the tendency of the farmers in this part of the State is to let it mature a little more before cutting. This is especially the case where it is to be used for horse feed. One of my neighbors ordered a carload from Imperial Valley, with the stipulation that it was not to be cut until well matured. Others are taking the same precaution. Alfalfa, when cut before blooming, is the source of much trouble among the dairymen. It is often dangerous to feed when cut before blooming, on account of being poorly cured. It then causes bloat to an alarming extent among cows. I lost one cow from that cause, and saved another only by the prompt arrival of a veterinary. If allowed to get thoroughly dried it crumbles and powders when it has been cut too early until there is great waste. If baled too green and damp, as most of it is, the center of the bales is moldy.

* * *

P. 601, Sept. 1, Mr. Byer says, "I heard a farmer once say that farming is a gamble on the weather." This reminds me of hearing a merchant tell several farmers who

were sitting around his stove that, if farming was not the best business on earth, they would all have been broken up long ago. I have thought of his expression many times, and am convinced he was right about the matter. If the average farmer in the middle West would spend as much for fertilizer, and practice the intense farming that is practiced on California orange-groves, he would get rich faster than many of those who have sold good farms in the East and bought orange-groves in California. But with beekeeping it is somewhat different, in that bees require much more attention in the East than here; and if the same attention were given the bees in this State as they receive in the East, the western beekeeper would fare more sumptuously. A neighbor said to me a few days ago that it is the Eastern beekeeper who keeps bees, but that it is the climate that keeps most of them in California. We have many excellent beekeepers in this State, but I think most of us will admit that the business is not worked on an intense basis here. I am sure that I do not follow mine as closely as I did while in the East.

* * *

I read in the last issue of *GLEANINGS* an account of the Hamilton County (Ohio) convention. Nothing strange about that to many; but to me it was of peculiar interest, it being my native county. My mother and father were born and raised in that county. Many of their reminiscences as told to their children are fresh in my memory. They are now nearing their fourscore years, having celebrated their golden-wedding anniversary several years ago. There was a custom in the early days of furnishing the harvest hands liquor in the field at harvest time. Mother and father were bitterly opposed to the practice, and made up their minds to get the grain cut without the use of liquor in the field. Father doubted if it could be done; but mother's strong desires in the matter were followed. There was some difficulty in getting it accomplished, but it was successfully done, to the astonishment of many of their neighbors, and the precedent was so strongly followed in the future that it was only a short time before the practice was stopped altogether, much to the advantage of the farmer as well as to the benefit of the men themselves. It is easy to join a popular movement; but when two young people start an unpopular movement like the above they deserve the gratitude of the community.

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

THE "MOVIES" AND BEEKEEPING.

Moving pictures are all the rage; and while there are some objectionable features connected with the way the moving-picture business is overdone, yet there are some very good lessons that can be learned from them. I have often objected to the too constant going to moving-picture shows, especially of school children. Another objection is raised against pictures that ought not to be shown on account of the evil effects that they may have, especially upon the younger people. But there are many films of a purely educational nature, and many of these are valuable indeed, as much can be learned from them that would otherwise remain unknown to many persons who do not have the opportunity to travel or even read about these things.

Making use of the educational feature of these films is something that has been uppermost in my mind for several days this week, and it may be of interest to mention the reason for this. It happened that one of the picture-film concerns decided to make up a film of scenes illustrating many of the different industries we are engaged in here at New Braunfels. This is to be shown here in our local picture shows first, and then this film will make the rounds of the company's circuit of a large number of cities and towns of the State. In this way a wide distribution will be obtained, and the advertising feature of the film should be worth considerable to our city, and to those who are represented in the various industries displayed by it.

Beekeeping, in connection with poultry-raising, as a hobby and side line, will be displayed as being the business or industry represented by the writer. Handling the bees in the apiary and removing some honey, the very thing that we produce for sale, and that we want to advertise, and this followed by views in the poultry-yards, from which fine stock and egg-settings are our specialty makes interesting picture-show stuff. Each firm or individual is entitled to a title preceding the pictures that are reeled off, which will explain what follows in the scenes.

It occurs to me that such film displays should aid in advertising one's business, to a certain extent at least; and if the title preceding one's industry is worded well, good results should be obtained. It depends, of course, how a thing of this kind is shown up, and whether the title and what follows will awaken the thought that we

would like to have awakened to bring the results desired. In addition to this the question arises as to the cost of such round-about advertising in comparison with the results obtained.

The charge for making up a thousand-foot reel, showing our various industries of the city of New Braunfels, is based on \$200 for the cost of the entire film. Thus each subscriber represented is charged 20 cents per running foot, according to the number of feet that he wishes to use. A hundred feet, therefore, would cost \$20.00. While a hundred feet does not run a great while in a single show, it is true, yet it must be figured that such a film will be run over and over again in many different places during its circuit; and even after such a circuit is completed, the film may be taken over by managers of other circuits if the film is interesting enough. Just what will be done with the film we are having made here, and what the consequent results will be, is difficult to predict; but we hope to be able to report at some later time whether the venture has been a success or failure.

Right in connection with the above I have thought that entire films made up of interesting matter about the handling of bees, hives, etc., the honey, honey put up in nice packages, and stored on the shelves in glass, with proper signs at various places all through the film, bearing the words "Honey for Sale" would be an aid toward creating a greater demand for honey. Proper titles scattered throughout the film scenes could be made to explain in such a manner *that the spectators would be honey hungry by the time the end of the film is reeled off.* This sounds like a fairy tale, and there may be something in it. In order to ascertain the value or the failure of such advertising, only a trial is necessary, and it seems to me that the National Beekeepers' Association is the body that should make such a trial. The funds of the old League, subscribed for the purpose of advertising the beekeepers' products, should be available for this purpose. I believe that several good films could be made up that would be a real credit to our industry; and if gotten up with the proper care, and the advertising idea kept carefully in view, good results ought to be obtained. The cost, however, in comparison to the effect that such film advertising would have on the demand for honey, may be too great. That would have to be investigated. If it is not found to be so, I should like to see an experiment of using the "movies"

Conversations with Doolittle

At Borodino, New York.

DIFFERENCE IN BEES.

"Is there a difference in bees as to their characteristics, ways of working, etc.? I was told a few days ago that there is as much difference in bees as there is in any of our domestic animals."

Nearly all practical beekeepers recognize that there is a great difference in the varieties of our bees, while the most observing are free to admit that there is quite a difference among colonies of the same variety. I hardly think that anybody having had very much experience would say that all bees are alike in temper. I believe he would be ready to admit that some colonies are more vicious than others. Bad handling will make almost any colony of bees ugly; but there are some colonies that are so cross that it is almost impossible to open their hives unless they are thoroughly subdued with smoke.

I had a colony of dark Italian bees once that I could hardly to do any thing with, while nearly all the other colonies having queens from the same mother were so quiet that they could be handled without veil or smoke. But with that colony it was with much difficulty that the hive could be opened and the combs lifted out unless an assistant kept smoke pouring in upon them all the time. And this trait was characteristic of them until I made a change of queens.

Some colonies will cap their surplus in the sections white, while others will cap so closely to the honey that all of their output will have to be classed as second. Some colonies will fill the sections with honey completely, capping even the cells all around next to the wood, while others will leave "peep holes" in each of the four corners, and sometimes the comb will not be secured to the sections on the sides at all—just attached at the top and bottom. Then some colonies will build comb only when there is a fairly good flow of nectar, stopping whenever there is a slight scarcity caused by a few cool or rainy days, so that the completed sections have an uneven or "washboardy" appearance. Other colonies, when they commence in the sections, expect to fill them without stopping to think whether the nectar yield fail before they can complete the sections. Hence the whole super or supers of sections come to a finish as smooth and perfect as if planed and sandpapered. I once had a colony which gave 309 pounds of such section honey, and used this difference in comb-building to great advantage by stocking three-fourths

of the colonies in the whole apiary with young queens from the mother of this colony.

Some colonies will gather great quantities of propolis, and plaster it all over the sections and separators till it runs down and collects in drops in the corners, much to the disgust of the one who has the sections to clean for market. Other colonies will plaster the combs with propolis, thus spoiling them for future use as bait sections, and giving the cappings of such combs as are marketable a disgusting appearance to the one desiring to purchase honey. Other colonies will put in burr and brace combs between the supers, or between the supers and the hive below, often attaching these to the separators and the nice cappings on the face sides to the combs in the sections, so that, when the honey is removed from the supers, the chunks of capping partly, if not entirely, spoil the salableness of such sections.

Some colonies will work earlier in the morning and later in the evening, and keep persistently at it, when the scales will show only a few ounces gain each day, while other colonies seem to think there "is nothing doing," and so loaf about the hives all day, or try to rob these industrious ones. The business thrift of other colonies is very marked. With a far smaller number of bees than some of their neighboring colonies have, they are continually increasing their stores, and at the end of the season they will have much more to show for their season's accumulations than will colonies that were more populous in early spring.

Some colonies gather more pollen than is needed, crowding the brood-combs so full that there is hardly room for the queen to occupy with eggs for the well-being of the colony, or spoiling much of the section honey by filling with pollen many cells throughout the whole super.

Much more might be said in regard to the variation and different traits of different colonies; but the point I am anxious to bring to bear upon all who read these lines is this: All these differences hinge on or depend upon the queen and the drone with which she mates. We say this colony does this, and that colony does that; but in reality the whole depends on *one individual bee*, and that is the queen. Hence it is to the interest of each beekeeper to know that all his queens come up to the highest score along all the different points that tend toward perfection.

WHITEWASHING IN PLACE OF PAINTING HIVES

Painted Wood Not as Porous, and Therefore Not as Good for the Bees

BY M. G. DERSVISHHEIM

The walls of beehives should be porous on the same principle that human clothing should be porous. The feathers of birds, too, are arranged so that there are air-spaces. Porous matter is not conductive of heat and cold, just as the human clothing is not, and keeps its contents in natural heat. Ice is wrapped in felt to prevent the cold from escaping and the outside temperature from penetrating. If one's clothing were made of India rubber or of oilcloth the body would be in an unclean and unhealthy state. The hive is the clothing of the colony of bees, and is intended to retain the heat and to let the damp and gas produced by the breeding and breathing of the bees escape. Wood, especially that of a soft quality, is porous, and therefore it is the best material for the hive.

In olden times, most hives were made of straw. Straw skeps, I believe, keep the bees in a dry state and warm—the former owing to the porousness, and the latter owing to the dead air contained in the straw. In the eastern parts of Europe and in Asia Minor most hives are made of dome-shaped baskets, and the outside of these is covered (plastered), about one inch thick, with mud consisting of earth and cow's manure. These hives keep the bees in a very comfortable state.

Hives made of wood come second, but owing to the great advantages derived from modern improvements in apiculture there is no doubt that wood is the best material (especially soft and light wood) for the construction of hives, provided it is not rendered impermeable by the application of oil paints, etc.

In winter and spring the inside of a hive occupied by a strong colony and covered with any impermeable material, such as oilcloth, gets wet owing to the vaporized water from the breathing of the bees, to the greater consumption of honey, and to the insufficient porousness of the body of the hive. Part of this vaporized water leaks from the entrance in a condensed state, and this shows the excessive amount of dampness. No doubt such a state is harmful to the bees within.

I strongly recommend whitewashing with quicklime. It is the cheapest and easiest

method. It is known to everybody that white reflects the heat from the sun, and the hives look nice and clean.

Take six pounds of quicklime, sprinkle on this by degrees about a gallon of water. When it gets hot, and the quicklime swells and cracks, sprinkle more water. A little later pour on about four or five gallons of fresh water and mix it with a rod and then take about half a pound of alum, break it into small pieces and melt it over a fire with a little water. Or better, pound it and mix it with the prepared lime for whitewashing. This alum makes the whitewash stick well to the wood and does not come off on one's clothes or hands when handling the hives. In the absence of alum ordinary cooking salt can be used, but alum is preferable. This whitewash can be applied quickly with a broad whitewashing-brush.

For the purpose of observation, for 12 years I have made use of several hives not painted and some which were painted. The inside of the hives which were painted became as black as if lamp or chimney black had been applied, while those which were not painted have remained light brown in color, which is, of course, the color of propolis or polish made by the bees. I recommend that progressive apiarists try a few unpainted or only whitewashed hives and then compare them after one or two years with the state of the painted ones. At the same time I also recommend that in winter and spring they use on the frames quilts of porous material, for instance of cotton wool, or bags filled with chaff or sawdust. I make use of empty merchandise cases which serve for protecting the hives on all sides from the direct rays of the sun. My way of covering the top of the brood-nest is with boards $\frac{3}{8}$ inch thick. In this semi-tropical climate (35 latitude) this permits the dampness to escape very slowly through the thin strips laid over the top-bars of the frames, gives very slow ventilation, and allows escape of dampness in winter through the joints.

For higher latitudes I should think sawdust or chaff cushions over the frames would be best for winter. A chaff sawdust, with two or three sheets of rough brown paper underneath, will keep the heat without preventing the escape of dampness, and will drive out the dampness.

On p. 812, Dec. 15, 1912, Mr. J. E. Crane, as foul-brood inspector, reports, "I found the bees in box hives in decidedly better condition, as a rule, in the spring, than those in frame hives." He says further, "One

man asked me in regard to changing from box to frames, or patent hives as he called them. 'Don't, don't,' I said, 'unless you are going to use frames,' for of what earthly use are frames in a hive unless they are used by a beekeeper? They cost more, and are not so good." I have reason to believe that the box hives referred to are not painted, and if I am correct the better state of the bees in the spring is owing to the porousness of unpainted wood—that is to say, the hive is free from dampness. And the state of the colonies in movable-frame hives is not as good as in box hives, because there is less chance for the dampness from the painted walls of the hives to escape, paint having rendered the wood impermeable.

In Bulgaria I have seen hives made in the shape of a bell, the same as straw skeps, but much wider and taller. These are practically like baskets turned upside down and covered with a kind of plaster made of earth. Such hives are extremely porous. Bulgaria is about 43 latitude. Cold is severe in wintertime, and yet bees are very comfortable in this kind of hive, and they are wintered outdoors.

Nicosia, Cyprus.

SOME OLD HONEY

Samples from Ten to Thirty Years of Age

BY R. C. AIKIN

On March 27, 1884, I reported to the *American Bee Journal* that bees wintered well on summer stands, and in fine condition at that date. See p. 218, for April 2d issue. In the Sept. 24th issue of the same year on p. 621 appears the following letter:

Worst season for ten years. We have no new honey this year, and all of the old honey is gone. I have 80 colonies of bees, and not five pounds of honey. One man had a little early honey at the fair, and he will have to feed that back for winter. We have less honey this year than for ten years past. Can not some one send us enough for a taste when company comes?

Shambaugh, Iowa, Sept. 15.

R. C. AIKIN.

Some time after this letter appeared, a preacher, a friend of mine, handed me a quart bottle of honey which had been handed him by some friend where he had been preaching, or at some meeting, in another part of the State. The bottle was filled with extracted white-clover honey, and a label on it which read as follows: "The Promise is Fulfilled. This is the land that flows with milk and honey, and here's the honey from H. M. Noble's apiary.—Swedesburgh, Iowa, 1871." Later I changed the label date to 1884. I suppose he put on the old one just to give his address, etc.

That is all I know of Mr. Noble. I think I wrote him one time about the honey, but never had any communication from him. The bottle was set up in my honey-house, and stood around for several years. At one time it lost its cork and stood open for some time, and a few wax-moth-larvæ droppings got into the honey, and then I recorked it. No record was ever kept, but within probably a year or so the honey candied. Still later it partially liquefied, then a thin layer recandied over the surface on top. That layer got displaced in handling the bottle, and sank to about the middle, resting one edge on the candied honey in the bottom, and the other edge against the bottle side, standing at an angle of about 45 degrees, where it has remained ever since.

I carried the bottle with me to Colorado when I moved there; then to Chicago, and had it on exhibition at the 1893 National convention; back to Colorado again; showed it some times at our Colorado State conventions; then brought it here with me two years ago last December. I have not sampled it for several years, but we used to taste it occasionally until about one-third of it disappeared. Of what is left, it has for some years been about half candied from the bottom. Very little change has been observed for the past ten or twelve years. When I received it, it was very clear; now it is a reddish dark shade about like sorghum molasses. It must be 29 years old this fall. I had this in Colorado for about 20 years, and in that climate the tendency of syrups is to become more stiff or thick. Now, after 2½ years, here it is still quite thick, even in this August weather.

BOTTLE NUMBER 2.

In 1889, at Fort Collins, Colo., I took a Hood's Sarsaparilla bottle and filled it with very clear alfalfa honey and set it up in the gable of the honey-house, close to the roof, above a window. That winter it candied solid, but the heat of the next summer partially liquefied it. Finally it candied from the bottom upward just about half way. There it stands to-day, and is before me on the desk now as I write. The candied lower half is about the appearance of lard fried from meat with just a tinge of dark. The upper half is clear enough that objects can be seen through it, bottle and all, and is of a reddish amber hue. The bottle is sealed, and has been opened very few times since filled, and not at all for several years. It seems a trifle thinned on top, but shows no sign of ferment. This is 24 years old.

SAMPLE 3, JUST OF AGE, 21 YEARS OLD.

This is probably alfalfa and sweet clover mixed, or at least from one of these sources.

It is in a vase of globular form, the bowl being in outside measure about seven inches wide and a good six deep, then the neck and mouth is straight, and about $3\frac{1}{2}$ inches opening, the inside of neck being ground, and a glass ground stopper to fit it just as bottles are made with glass stoppers.

This sample was produced at Loveland, Colo., in 1892. As is usual in case of all extracted honey there, it promptly candied, and with compact close grain resembling lard. How long it remained candied I do not remember, but, as nearly as I can recall, it largely liquefied within three or four years, and gradually in part crystallized until about half of it was of crystals about twice the size of ordinary plasterer's sand. Once the vase in moving got wrong side up, and a little of the liquid oozed out. Now it stands with the lower half liquid with crystals in it; the upper half just crystals. It looks like a very coarse light-brown sugar. There is just a possibility that I once applied heat, and liquefied this, but can not now tell. This vase has been unstopped often, and is not sealed only as the honey clinging to the ground stopper seals it.

NUMBER 4, 19 YEARS OLD.

This is in a twin vase to number 3. It is probably alfalfa and sweet clover. I know that in those years we usually got some alfalfa flow in June and July; then in July and August the clover and the mixed crop harvested together. I had no thought then of how long those samples would be kept, nor of how interesting would be a full history, so kept no records. Later I began to realize my mistake, and to put date records on them. I now wish that I had complete records.

This sample I think has never been liquefied by artificial means. I know that, like all extracted honey there, it candied as solid as fine-grained lard. I can not remember all of its changes, but to-day it stands with a little better than half, the lower half, looking like so much scorched lard, and is compact as would be so much dirt settled in a pail of water; the upper portion being a liquid with no granules in it, is of a dark reddish-amber shade. This, and sample No. 2 that is 24 years old, are almost identical in appearance in the candied lower half, being like so much scorched lard, and compact at the bottom, and the liquid part at the top, and of amber color. There is an abrupt change from the candied to the liquid.

SAMPLE NUMBER 5, 18 YEARS OLD.

This is in a quart Mason fruit-jar. It was produced at Loveland, Colo., in 1895, and was liquefied and exhibited at the fair in 1896. It is full, and sealed as fruit is

sealed in these jars. To-day it stands with the upper third of very coarse granules like sugar; the lower two-thirds is an amber liquid with coarse granules all through it. I think that those Colorado honeys almost invariably granulate very fine at first, but after being heated the second granulation is a truer crystallizing, but never solid. I have repeatedly noticed the older once-melted honeys showing that tendency to form coarse crystals scattered throughout the liquid.

These samples as they grow old are becoming more and more interesting to me. I often look at them, and recall the strenuous days when in my prime I was wrestling with bee problems. The two vases have for years stood either on top of my desk, or on the bookcase, or somewhere in the living-room, constantly in the light, and have been knocked about, sometimes being taken to fairs or conventions. They make a pretty ornament in the room. Each vase contains about a gallon of honey.

I have a sixth sample in a quart jar. This is just a remnant of dry granules. The jar not being sealed tightly while moving, the liquid leaked out. I have just sampled it, and it still tastes like honey. It is 17 years old. I did have other samples 20 years old and even older, of different sources of bloom, but they were put in tin pails, and the pails corroded, and spoiled the samples. There should be no metal in the receptacle for preserving honey samples.

Blessing, Texas.

A BEGINNER'S EXPERIENCE

How an Amateur Starting with a Stray Swarm became the Owner of Thirty-four Colonies

BY C. E. BUSH

I have always had a distant respect for the honeybee; but my actual experience with bees dates back about a year. My father hived a stray swarm, and then I became interested in bees, and the bees became interested in me.

A second swarm came, and we hived that. After that it fell to my lot to take care of the bees, with the friendly assistance of one of our neighbors, who is also somewhat of a novice with bees. Equipped with an old hat, a good-sized piece of mosquito-netting, and a pair of old gloves, with some sock-legs sewed on for gauntlets, I began to think that I was really a beekeeper.

The next summer we caught three swarms. I took one of them from an old tree, and another out of a hay-barn. The one taken

from the barn was a very large colony, and it was necessary to make three trips in order to get all of the bees. This one stray swarm made two good-sized colonies and a small one. I paid the neighbor fifty cents to catch a swarm for me, making a total of seven colonies. Then I became very enthusiastic and bought ten colonies, going thirty-five miles in December to get them.

In February I took two first-class beemen into my apiary to look my bees over. We found that one colony had been robbed out. One of the men remarked that conditions seemed to indicate foul brood. We opened the hive, and there we found foul brood in an advanced stage. We examined the rest of the colonies, and discovered that four others were diseased. If any beekeeper knows by experience how a novice's heart gets sick, then he will know how I felt. The two men whom I mentioned before told me that I would have to clean up the apiary, and explained how to do it by the McEvoy treatment.

I had a tank built in which to do the boiling. One of the men came over to help me. We shook the bees on some old comb and fed them some warm syrup. Then came the process of scalding and cleaning the frames, etc. After I took my assistant home, the rest was left to me. On the evening of the fourth day I took the clean hives and removed the old hives on the stands, placing the clean ones in their places. I shook the bees upon new clean foundation, and on some pieces of clean comb I tied into a frame in each hive. I supplied them with some more syrup, which they cleaned up and put in the comb.

I fed them again on the morning of the fifth day, and all seemed to be doing well until about three o'clock of the same day when two of the colonies left their hives and settled in the grass. I was stumped at first, but set my wits to work. I happened to remember that some one had said that a little brood would help bees in cases of this kind. I drove two miles and took from two clean colonies a frame each of brood and honey, returned home, relieved the bees, and gave them the brood. As soon as I set the hive before them on the ground, a few bees went in and discovered the new frames of brood. They rushed back and settled on the alighting-board, after which they "stood on their heads and waved their wings" for joy. Then it seemed as if the other bees of the colony could not rush in soon enough. I had no more trouble with them.

Thirteen colonies were left after the experience with foul brood was over. I bought one more colony. I then leased my bees to the man who had helped me clean up the

foul brood. I furnished the bees, half of the hives and foundation, and was to receive in return half of the increase and half of the honey. He was to increase all the bees would stand. In March we cleated the hives and cut burlap sacks in halves, putting one thickness of sack over each hive for a screen. We also screened the entrances. We started out one morning early to move them twelve miles, arriving at the out-apiary about 1 o'clock in the afternoon. As the sun was shining warmly it proved to be a very hot day. As a result we lost two of the strongest colonies. That left just an even dozen. My friend was equal to the difficulty, however; for after taking charge of the bees he succeeded in increasing them to thirty-four colonies. The bees, too, did their part, for they made stores enough to keep them through the winter.

Ceres, Cal.

Horse Stung by a Swarm; Who was Responsible?

Will you kindly give me your opinion on the following case which happened in this neighborhood some time ago, and which may cause considerable litigation?

A and B are neighbors. A has a lane past B's house 16 ft. wide. B keeps bees in a back lot which is $2\frac{1}{2}$ rods from A's lane. One day as A was coming along his lane he saw a swarm of bees near the far end flying around a tree which is just on the other side of his lane and some distance from the beeyard. A does not wait for the bees to settle, but tries to drive through them. A escapes without injury, but the horse is so badly stung that it dies. Knowing that the swarm came from one of B's hives, can A hold B responsible for the loss of the horse, and collect damages?

A. B. C.

[In answer to your question we will say that a good deal will depend on whether proof can be produced to show that the bees that stung A's horse were actually the property of B. For instance, if Mr. B admits that the swarm came from one of his hives, or if one or more persons testify that such swarm issued from one of his hives, and then occupied a position in the highway, as described, possibly Mr. B would be liable for partial damages. In that case we would recommend Mr. B to arrange a settlement with A if he can do so. If, however, there is no proof to show that the bees came from Mr. B's yard, that it was a vagrant swarm, coming from nowhere, then B is not liable. It does not follow that because Mr. B owned bees that the swarm in the highway was his property. As we understand the matter, the burden of proof rests upon Mr. A to prove that the bees were the property of Mr. B.

In any case, we do not believe that Mr. A can collect full damages; and we do not know that he could, even though it were proven that the bees in question belonged to Mr. B. Mr. A had the right to the use of the highway; but if he *knew* the bees were in the highway, and *deliberately* drove through the flying bees, and that fact can be proved, the damages, if any, would be nominal. We should think it would be what would be known in court as a case of "contributory negligence." But assuming that Mr. A and Mr. B are neighbors, it would be desirable to have them adjust this matter equitably among themselves if they can.—Ed.]

Apiary of J. L. Strong, Clarinda, Iowa, which has been its owner's sole dependence for many years.

BEEKEEPING AS AN EXCLUSIVE BUSINESS

BY FRANK C. PELLETT

The general tendency is very conservative toward our industry as a business. We are free to advise the keeping of a colony of bees in the attic, or a few hives in the back yard to supply the family with honey and the beekeeper with an interesting diversion. Enquiring beginners are always warned against taking up honey production for a livelihood because of the fact that some seasons fail to supply a profit.

While to begin beekeeping on a large scale without previous experience and a thorough knowledge of the business would certainly prove disastrous, the same may be said of any other business. Beekeeping requires high-grade talent to handle it successfully, and one should never consider beginning in any but a small way, and increasing as experience and inclination justify. On the other hand, the men of my acquaintance who depend upon honey-production for a livelihood get as large an income on the average, with less capital invested, and less wear and tear, than in other lines of agriculture. We have been entirely too conservative regarding the possibilities of honey production, and I do not hesitate to say to those who wish to know whether they

can make a living in the business that, if they will master it fully in all its details, they can do well at beekeeping.

There are many advantages also. The beginner can start with an investment of only a few dollars, and learn the ins and outs of beekeeping while attending to his other business, and not relinquish his source of regular income until such time as he gives the matter a thorough test and has had an opportunity to determine whether he is fitted for the work.

The first essential to success, of course, is a good locality; for without a suitable flora the bees can not gather a profitable crop. Given a good locality, the rest all depends upon the man.

Among the successful beekeepers of Iowa, three men are conspicuous; and these may be, perhaps, considered typical of the lot. J. L. Strong, of Clarinda, has kept bees for 46 years, and for more than a quarter of a century has made them his sole dependence. His home and business have been paid for from the profits of his apiary. In addition to honey production he does an extensive queen-rearing business, and depends for the most part on a single yard which he keeps at home.

F. W. Hall, of Colo, has been in the business for many years, and his standard of living is as high as that of the wealthiest

people of his community. His home is among the finest in the town, his daughters are college graduates, and the family enjoys every convenience and advantage of education and travel.

B. A. Aldrich, of Smithland, has been engaged in general farming on rented land for years until recently. Failing to make this line of work profitable he closed out every thing but the bees, which he had found profitable as a side line, and devoted his attention to them exclusively. Mr. Aldrich says that the only mistake he has made was in not dropping the principal business and devoting all his attention to the side line several years sooner. Mr. Aldrich harvested a crop of nearly 14 tons of honey from 300 colonies last year, and bids fair to do as well, or better, this year. He has the finest equipment in the way of a honey-house and labor-saving machinery that I have ever seen in the hands of any beekeeper; and by this means he is able to do nearly all his own work and thus reduce his expenses to the minimum, which is, of course, impossible with general farming.

In the face of such examples as these we surely need not fear to recognize beekeeping as a dependable pursuit. If a man will recognize the fact in the beginning that there is something to learn, and that to be successful he must go about it in a business-like manner, and observe the same caution that he would do in undertaking any other line of business with which he is unfamiliar, the chances for success are better, in my estimation, than in most other lines which are highly specialized.

Atlantic, Iowa.

Home of F. W. Hall, Colo, Iowa.

is more in harmony with the nature and habits of bees. Colonies wintered in the open with suitable protection will usually have several cleansing flights at frequent intervals, thus enabling them to void their excrement in a natural manner.

Since it is my purpose to measure up the situation with nature's try-square, regardless of any preconceived ideas, perhaps a little nature study along these lines may help to a better knowledge concerning the domestic economy within the hive. It has long been a source of conjecture among beekeepers why an old box hive with open cracks admitting chilling drafts will carry its colony through the winter in safety year after year, in open defiance of all theories relating to moisture, ventilation, and protection. But this is nature's handiwork, unmolested by the blundering hand of man; and a closer scrutiny reveals the fact that the internal arrangements within that hive are in perfect harmony with the habits of bees, wherein every angle and curve of the combs betokens a wisdom of architecture beyond the power of man to comprehend.

Our first thought upon opening such a hive is, "Why do the bees build their combs so crooked and irregular?" but if one looks a little closer he will notice that there is "method in their crookedness," since many are converging toward the center like the spokes of a wheel; and if the examination is made in mid-winter the cluster will usually be found in the center, as represented by the hub of the wheel. The wisdom of such an arrangement will be more apparent when one understands that it is the habit of

THE OUTSIDE WINTERING OF BEES

A Nature Study

BY J. E. HAND

The outdoor wintering of bees is practiced with varying results throughout the United States, and even in portions of Canada, where it is rapidly coming into favor. Beekeepers everywhere are coming to realize more and more that open-air wintering

bees, so far as conditions will permit, to cluster together in a solid ball as a means of protection against extreme cold. Since this is nature's method, it is safe to assume that, in no other position, have the bees equal power to resist cold. It will be noticed that this arrangement enables the cluster to remain in the center of their base of supplies, and also admits of expansion of the cluster during a warm spell to bring a new supply of food within reach of the cluster. Likewise, it allows contraction during a cold period without the loss of bees that otherwise would be caught on the outside of the solid slabs of cold honey, and perish. While bees are sluggish in their motions in winter, when undisturbed, they are not hibernators; and if a small bunch becomes separated from the cluster, being of insufficient numbers to create sufficient heat to sustain life, they will soon perish with cold. It is thus that colonies are often greatly depleted in numbers in modern hives where no provision is made for the expansion and contraction of the winter cluster.

At first sight the bees composing a natural winter cluster appear to be in a semi-dormant state. Such is not the case, however. On the contrary, they are keeping up a constant circulation inward and outward. It is thus that motion, combined with the heat of their bodies in close contact, will enable them to maintain a normal brood-rearing temperature in zero weather, such is the wonderful heat-producing power of a cluster of bees under normal conditions. These are nature's methods untrammelled by man, who deludes himself with the idea that he can improve upon nature's methods. But let us take a view of the internal arrangement of a modern hive, as ordained by the wonderful wisdom(?) of man.

The first thing that attracts one's attention is the absence of sufficient space below the frames to accommodate the winter cluster when suspended in a solid mass from the lower edge of the combs, according to the habits of bees at the beginning of winter. Likewise, the close spacing of frames that is practiced under modern methods leaves no opportunity for a winter cluster in sufficient numbers to maintain a normal temperature by natural methods. On the contrary, they are compelled to spread themselves out in thin layers between solid walls of cold frosty honey, and every layer separated from its neighbor, with no means of communication between them, except by traveling around the outside of solid slabs of cold honey, which would mean certain death. Thus in this unnatural and isolated condition they are unable to employ nature's method of heat production; and, having no

other alternative, will resort to an abnormal consumption of food in a vain attempt to maintain a normal temperature, and the result is likely to be death or clogged intestines, followed by dysentery. As a last resort bees will crawl into every empty cell within reach, where, if the weather is *very* severe, they will be likely to be found dead in the spring.

THE WINTER NEST.

What is the result? The beekeeper comes along in mid-winter to inspect his bees, and, finding them in the condition just described, instead of getting down to the root of the matter, and reasoning from effect to cause, he jumps at the conclusion that a winter nest composed of empty cells, into which bees can crawl for mutual protection against cold, is an important factor in successful outdoor wintering; he even intimates that the honey was removed from those cells for the express purpose of forming an alleged winter nest; while in reality the presence of empty comb in the center of the brood-chamber is easily accounted for from the fact that they were occupied with brood until after the close of harvest. While a winter nest composed of empty combs might well be chosen as the lesser of the two evils, it is entirely inadequate to the needs of a winter cluster, since its presence endangers the life of a colony just in proportion to the amount of empty comb involved. Undoubtedly the importance of an alleged winter nest has been slightly overestimated; and the wise beekeeper will see to it that there is no considerable amount of empty combs in the center of the hive at the beginning of winter.

Let us take a view of the internal arrangement of a modern hive equipped with the improvements suggested, and measure them up with nature's try-square, one by one. First, a liberal space below the combs, said combs being solid full of honey, will ensure the clustering of the bees in a compact form, suspended from the lower edge of the combs, and below their base of supplies, which is the natural position of a cluster of bees at the beginning of winter. It is the habit of a winter cluster under normal conditions to move upward instead of sidewise until a brood-nest has been established. Therefore as the season progresses, and the consumption of stores removes the base of supplies too far from the cluster, in order to keep in touch with their base of supplies the cluster will advance to a natural position in the center of the combs. Here, in the center of their base of supplies, and in a position affording ample provision for the expansion and contraction of the winter cluster, through the center of the brood-

chamber, horizontally as well as vertically, with full and free communication among all the bees in the cluster, they will establish a permanent clustering place, wherein their brood-nest will be established. Mid-winter brood-rearing will begin according to the habit of bees in a normal condition. The importance of wide spacing is not so apparent when other conditions are right, and nine frames in a ten-frame hive is sufficient.

This method, when measured with nature's try-square, would seem to harmonize with the habits of bees; and since it approaches as closely to box-hive conditions as is possible under modern methods where straight combs are imperative, it should give equally satisfactory results in wintering. Thus, while we may not improve upon nature's methods we can imitate them so closely as to give equally good results.

Birmingham, Ohio.

BRINGING COLONIES THROUGH THE WINTER STRONG

Higher Temperature and More Ventilation Needed

BY WILLIAM BEUCUS

The editor of GLEANINGS has long and earnestly persisted that bee-cellars should be abundantly ventilated. Doolittle, on the other hand, has insisted that ventilation is

not necessary. Until the last year or two I was inclined to side with Doolittle, for we have wintered our bees with good success without excessive ventilation, and sometimes without any ventilation whatever. In the winter of 1909 our loss out of 140 colonies was nothing. In 1910, 160 colonies wintered without loss. In 1911, six out of 176 failed to live through the winter. One of these was queenless; one starved because of too much pollen and too little honey; four had been weakened by the attacks of a skunk. In 1912, '13, the bees again wintered successfully, and there were 192 colonies. Many will say, "What more do you want?" The answer is, "Stronger colonies in the spring." We want every bee that can be saved. We have learned to carry through every colony, now we want to carry through every bee—if that is possible.

The endeavor to carry through all bees led me to the practice of ventilation. I have been troubled during the past three winters with bronchitis, and consequently have been very sensitive to changes in the environment. On the first of each month, all dead bees are swept up and measured, which requires some time. Each time this was done, the bronchial tubes felt raw. Why? It certainly was not the low temperature, for it was warmer in the cellar than outdoors, and no rawness was felt out-

doors. It could not be dampness alone either: for on wash day, when there was an unusual amount of moisture in the house, no ill effects were experienced. That rawness was due to a combination of two conditions—low temperature and damp atmosphere.

Why is one afflicted with colds and bronchitis in the winter, any way? A right answer to the question will shed some light on the question of wintering bees better. There are in the human system four avenues for the escape of moisture and impurities—the bowels, the kidneys, the lungs, and the skin. In the summer the skin is very active the most of the time. Fresh vegetables and fruit are eaten in abundance, which aid in keeping the system in good condition. Fresh air is breathed almost all of the twenty-four hours of the day. The moisture and impurities have abundant opportunity to escape as fast as formed. But in winter the skin is inactive. One does not perspire so much. Fewer fresh fruits and fresh vegetables are eaten, which clogs the system, and impure indoor air is breathed a great deal of the time. Now notice. These acute diseases come in the winter with the four avenues for the escape of impurities sluggish but still open.

How is it with the bees? They have but three avenues for the escape of moisture and impurities—the bowels, the malpighian tubules, which take the place of kidneys, and the tracheal tubes, which take the place of lungs. But when the bees are placed in the cellar, conditions are imposed which close entirely two avenues for the escape of moisture and impurities—the bowels and the malpighian tubules. Thus there is but one avenue left open, and this is obstructed. How is it obstructed? By the moisture present in the atmosphere. Evaporation can not take place rapidly in air which is already at the dew-point. Is it any wonder that the bees become uneasy, and fly out on the cellar floor to die?

Bees are not great exponents in the winter; but in maintaining a comparatively high temperature for five months there is sufficient waste to demand an easy escape for moisture and carbonic-acid gas.

What evidence is there that bees are needlessly dying? Go into the bee cellar and stay a while with a lantern. Occasionally you will notice a bee which flies vigorously. Take a few of these into a warm living room and notice what follows. Occasionally one will preen itself for two, three, or even five minutes. Is it getting ready to die? It doesn't look that way. Now give it a little honey. Its vigor is quite inconsistent with superannuation. It seems a

Cover removed, showing the hive inside the concrete winter case.

fair inference that these bees leave their hives because they feel uneasy. I have frequently raked into a cluster of bees in the cellar when removing dead bees from a shallow entrance, but the bees did not fly at the light. They hurried back to the cluster. Last February, with a temperature of 50 in the cellar, four feet from the floor, I stood before a colony with a lighted lantern. The bees were loosely clustered, and some were quietly resting on the bottom-board an inch away from the cluster. They did not fly at the light. I touched one of these isolated bees. It immediately "stood on its hands" and moved sluggishly toward the cluster. A little later I called my wife down to look at a powerful colony which had become so uncomfortably warm near the ceiling that the

Bosserman's winter case is made of $\frac{3}{4}$ -inch slabs of solid concrete bolted together at the corners. Wooden cleats are also bolted on for a hand grip. One case weighs from 65 to 80 lbs.

bees had come outside and clustered on the front of the hive up to the hand hole. I held the lantern up within two inches of the cluster. There was a slight movement among the bees, and one bee raised up and buzzed its wings a little. That was all. Not one bee left its place.

I will tell you why. We put in a hot-water plant last winter; and to lower the temperature of the cellar we found it necessary to open the inside cellar doors, leaving the outside ones shut. That gives us a temperature 8 degrees higher than it used to be before the plant was put in, and such abundant ventilation that the air is dryer.

My cellar is 30 x 30, and is partitioned off so that the bees are in a separate room. The floor is cement, and the bee apartment is plastered overhead. The temperature in winter was usually 42. Last winter, with a temperature of 46 below outside, it was 38 above inside.

If Ira Barber could rise from his grave and read these lines he would no doubt smile and exclaim, "I told you so."

Cadott, Wis.

THREE DIFFERENT BEE-CELLARS COMPARED

The Right and Wrong Way to Ventilate

BY E. S. MILLER

For a number of years I followed the advice to beginners to winter my bees outside, with resulting losses varying from 10 to 50 per cent of the colonies. Then I began to think that there must be a better way, and to hope that, before finishing, I might be able to work out a plan by which 100 per cent of all colonies might be carried through in good condition, providing, of course, they were in proper condition when placed in winter quarters.

Owing to the expense, labor, and uncertainty of results, packing in outer cases did not seem advisable.

About this time I bought another apiary and a few acres of land with a honey-house and a bee-cellar. But bees wintered in this cellar came through in a damp, moldy condition, and with a considerable percentage of loss.

Then a study was made of different modes of ventilation; and for the last five years my average loss in wintering has been about one per cent. There was a loss of only one colony in three winters in case of bees wintered in three cellars. During the past winter the loss was two colonies out of 274.

In order that the construction and mode of ventilation may be better understood I

will attempt to describe briefly three cellars, and compare results.

Cellar No. 1 is under a building, and is 18 x 20 x 7½ ft. It is in clay loam, and is made of solid concrete with cement floor and a plastered ceiling which is even with the level ground outside.

A nearly horizontal sub-earth ventilator extends from a point 30 feet west and enters near the floor. A chimney extends from the cellar floor to a height of about 20 feet, with an opening near the floor. The stove in the room above is seldom used, and it is not necessary for the purpose of ventilation. Door and windows are double; but the floor of the honey-house above has not yet been made sufficiently warm; and the low temperature resulting therefrom accounts, I think, for the losses. Usually the current of incoming air through the sub-earth ventilator, and the current out through the chimney are sufficiently strong to extinguish the flame of a lighted candle or match. A good current is always present at the opening near the floor in the chimney in cold weather, whether the wind is blowing or not; also at inner end of tube except when the wind is from the east.

The following temperature readings were made with a tested thermometer, and are worthy of consideration:

1913	Temp. Outside	Intake	Outlet	Wind	Draft at Intake
Feb. 19	54	46	45	S.	Moderate
Feb. 22	26	32	44	W. Strong	Strong
Feb. 24	12	32	40	None	Light
Feb. 28	32	36	40	None	Light
Mar. 2	2	18	39	W. Strong	Strong
Mar. 5	34	37	43	S. W. Mod.	Strong
Mar. 11	54	45	45	S. E.	Out, light
Mar. 14	64	48	48	S. E.	Out, light
Mar. 19	63	50	50	S. E. Strong	Out
Mar. 21	24	35	46	W. Strong	Strong

On March 20 a small amount of moisture could be seen at the entrances of a few of the hives in the lower tier, due to a lower temperature near the floor. Repeated tests showed the average temperature at the floor to be approximately one degree lower than near the ceiling; and the temperature near the ceiling was the same as at the outlet. By comparing maximum and minimum temperatures it will be seen that, while the variation outside amounted to 62 degrees, that at the intake was 30 degrees, and the cellar variation was only 10 degrees. Note also the modification of temperature in passing through the intake when there was a strong west wind. The bees (March 20) are quiet, and apparently in excellent condition. The cellar is dry, and with no perceptible odor. Number of colonies, 1912-'13, 104; winter loss, two.

Cellar No. 2 is ventilated in a manner similar to No. 1, except that the intake is about 100 feet long. This cellar is of brick, and is built in sand under a dwelling-house. The bees occupy a room partitioned off 12 x 12 ft., 87 colonies being stacked up five or six hives high. This room is much too small. Nevertheless, the bees are in excellent condition—dry, no odor, few dead on the floor; average losses about one per cent. The current at the intake is apparently stronger than in cellar No. 1. No temperature readings were taken, but the cellar is warmer than No. 1. Losses, 1912, none.

Cellar No. 3, 14 x 20 x 8 ft., made of cement blocks, is in stiff clay. It has four vertical air-shafts outside, extending from the ground surface, and entering the bottom of the cellar; also a dozen 4 x 4-inch openings at each end near the ceiling, which extend up from two to six feet through the cement blocks, and open outside. There is also a trapdoor into the attic, 1½ x 3 ft., which is left open in moderate weather. The spaces between the joints above the plastered ceiling are filled with dry sawdust. This is an excellent example of how *not* to ventilate a bee-cellar, notwithstanding many contend that an opening at the top is all that is necessary. In this cellar no air-currents are perceptible at the opening, either at the top or bottom. The humidity is usually about 100 per cent—that is, the air is completely saturated with vapor. Although the temperature is considerably higher in cold weather than in No. 1, the air is stagnant, odor bad, bees restless, and bushels lie dead on the floor. The small winter losses of colonies I attribute to the excellent condition of the bees due to heavy fall flows of honey. A sub-earth ventilator and chimney will be installed before another winter. Colonies, 1912, 98; losses, none.

Now, what can be learned from these examples? It seems to me that the several winters that these cellars have been used prove conclusively, first, that proper ventilation is necessary in the successful wintering of bees. Second, that, unless there is a chimney, the difference between the temperatures within and without a bee-cellar is not sufficient to produce convection currents that will bring about a proper ventilation. Third, that either a high chimney or a nearly horizontal pipe, entering at the bottom of the cellar, that will take advantage of wind pressure, or both, are the most practical means of forcing the air through and keeping it pure and at the proper humidity.

The question may be asked, "Why not pass the air in at the top?" There are two reasons. The first is, that the underground inlet modifies the temperature by making

the air warmer in cold weather and cooler in warm weather. The second is that, while in cold weather the cold air will drop to the bottom, being heavier, it will not do so when the air outside is warmer than that inside, and there will be little or no ventilation when most needed.

Valparaiso, Ind.

COLONY OF BEES TAKEN FROM A TREE IN FEBRUARY

BY J. S. FURNER

I have a colony of bees that I got last February in the woods two miles from my home. They were found by some boys hunting rabbits. I investigated, and found that the top of a basswood had blown off to a distance of about 20 feet, and the bees were in it. I got a man, crosscut-saw, and a democrat wagon, and went after them. I sawed the log off 42 inches long, nailed boards on each end, covered the hole, loaded the bees in, and in the summer they went to work as lively as any colony that I have.

The log is 22 inches in diameter, with an

Section of a tree containing a colony of bees. The tree was cut in February.

Apiary of J. T. Kight, Southport, Ind.

opening inside ten inches across, throughout the length of the log. There is nice white comb clear from the bottom to the top. I have a notch at the bottom through which the bees go out and in.

Lima, N. Y.

EARLY YIELD OF HONEY IN INDIANA GOOD

BY J. F. KIGHT

The spring and summer honey harvest is about to draw to a close (July 21). The yield has been very good in quantity and excellent in quality. Owing to about three weeks' drouth in June the white and alsike clovers were cut a little short; but while they did last, the bees carried in nectar with a rush. There seems to be considerable sweet-clover honey coming in now; but I can notice some falling off, as I have one good strong colony on a pair of scales, and the nightly balance is running only about $1\frac{1}{2}$ lbs. daily, while it ran as high as $6\frac{1}{2}$ lbs. during the palmy days of white and alsike clover in May and June.

As a rule the general honey crop in Indiana has been good this year, and in many localities there will be a flow of smartweed and aster honey this fall.

AN EXPERIENCE WITH AMERICAN FOUL BROOD.

I have had a little experience this year that was not on the program; and while I

have always dreaded the thought of disease among bees I can now say that I am really glad that it happened, although it cost me several pounds of good honey and the loss of some very fine wired comb foundation. Yet I do not regret this loss, for from the experience gained early in May I discovered that American foul brood existed in two colonies, and I asked the State Entomologist to assist me in going through my apiary of about 30 colonies at that time. He kindly did so, and we found seven pronounced cases of American foul brood. Having read of the different methods of treatment which really ended with the same results, also having before me the printed instructions of the State Entomologist I proceeded to make a cleaning.

As mathematics is my long suit, and not having the desire for any more labor than was necessary, I commenced to figure just the best, surest, and safest way to exterminate the disease. As all authorities on this disease seem to agree upon getting the bees out of the diseased hive and into a new clean one with starters only in the frames, I decided that there ought to be a better, quicker, and more sanitary way than to shake them as is advised by most authorities. I decided to try the driven method, instead of the "shook" method, which, in the end, amounts to the same, only the driven method is quicker, sanitary, and safer.

Here it is: Place the prepared hive with the starters in the frames on top of the diseased hive after removing the top board quietly, and puff considerable smoke in the hive entrance of the diseased colony. At the same time use a little hammer, and the bees are so frightened that they make a rush for the top of the hive without stopping to gorge themselves with the infected honey. After the first attack, I use less smoke, but keep pretty busy with the hammer. Within ten minutes every bee that can crawl is in the upper hive.

Remove the diseased hive to a new stand and place the driven colony on the old stand; and after 24 hours give the bees either full sheets of wired foundation or empty combs, and the work is complete. If there is sealed brood enough to warrant, one should leave enough bees in the diseased hive to keep the unhatched brood warm. At the end of 21 days repeat the drive; and by giving them a laying queen this second or after-drive will build up into a good strong colony by fall.

Under the treatment described above, the cure has been perfect; and from the seven diseased colonies I now have ten good ones. With this treatment, too, one does not expose any combs or honey to the robber; has no lifting, shaking, nor brushing of bees, and it is quickly over. I regret the loss of some honey and combs, but do not dread American foul brood any more.

Southport, Ind.

CURING BEE PARALYSIS BY ALLOWING THE COLONY TO REAR A NEW QUEEN

The Suspension of Brood-rearing Brings About the Cure

BY N. L. STAPLETON

I was very much interested in P. C. Chadwick's account, May 15, page 331, of his treatment of two paralytic colonies, and also in B. L. Fisher's account of the trouble he is having with his bees which I have just noticed, June 1, page 387. In my opinion there is no question but that Mr. Fisher's trouble is paralysis, and I think I can give Mr. Chadwick the secret of his success in the treatment he gave his diseased colonies.

I have never heard of any foul brood of any kind in Georgia; but bee paralysis is a constant source of trouble to all beekeepers in this section. Four years ago I introduced the first modern hives and the first Italian bees in this section of the State, and now have 95 colonies, consisting of both three-band and golden Italians. But before I started my apiary I used to notice among

Test hive on scales.

the farmers who used box hives, in practically every beeyard one or more colonies with a large number of dead bees in front, and disabled bees crawling around on the ground. The owner always explained that the bees had been robbing this colony, or that the web worms were killing it out. I still see the same thing over the country, and now know that the trouble is paralysis.

Soon after I began keeping bees, two of my strongest colonies developed this trouble, one of them being a colony which I had received by express together with a very fine queen, and I have had more or less of it in my yard every year until the present time. I read every thing I could find on the subject, and about all I found was summed up in the advice to requeen. I also wrote to J. J. Wilder, of Cordele, Ga., with whom I had been in college some years before, but he gave me the same advice. By experimenting I found that requeening would usually remedy the trouble; but twice it did not do so, and I had to requeen the second time in each of these cases in order to effect a cure. Here I desire to note two observations: The colonies affected have nearly always been my strongest ones, usually containing expensive queens which I hated to kill, and so far I have seen but two colonies recover without treatment; and these two which will be referred to had what amounted to the same thing—a suspension of brood-rearing.

The second spring after I entered the bee business I began experimenting, with a view to finding a simple treatment, and

have been at it ever since, but did not solve the problem until this season. Some writers have suggested that the old honey stored in the hive, and others that the old pollen in the hive, is responsible for the trouble, and that, so soon as new pollen and nectar are brought in, the trouble would abate. My observation does not sustain either of these theories. I have several times removed from the diseased colony all the honey and pollen in the hive, leaving only the center combs with the brood, and this, too, when a good supply of both nectar and pollen was being brought in. At other times I have fed sugar syrup. In no case has there been any perceptible improvement in the condition of the colony. Last season I attempted to introduce to a diseased colony a queen which I had received through the mail. The bees refused to accept her; and when I next opened the hive for the purpose of examination I found a lot of fine queen-cells. As a matter of experiment I took a couple of these cells and gave them to nuclei from healthy colonies, besides leaving one for the mother colony. They all mated; and not only did the mother colony recover completely, but there was never any trace of disease in the nuclei.

During the past winter, which was unusually warm, I had five colonies badly affected. In January I happened to open one of these and found a number of supersedure cells. This was so unusual that I watched this colony carefully. A queen hatched out in due time and remained in the hive for ten days or more; but a cold spell coming on, she eventually disappeared without ever laying. Soon afterward, when I went to introduce a queen to this colony, I noticed that it was entirely cured of paralysis, and I incidentally noticed that all brood had hatched out.

About the first of March we had a pretty fair honey-flow here from tupelo and other sources, and another of the diseased colonies swarmed, which was something else unusual, as I had never before seen a diseased colony build up sufficiently to cast a swarm, even in the best honey-flows. I attribute this instance to the warm winter. I hived the swarm and moved it to a new location, and in due course of time found a laying queen in the mother colony. Some three or four weeks later I was surprised to notice that there was no indication of paralysis in either the mother colony or the swarm. In trying to account for this, and in recalling some of the experimenting that I had done in the past, I came to the conclusion that the only thing that could account for such a prompt cure was the suspension of brood-rearing which had occur-

red in both the mother colony and the swarm.

As a matter of further experiment I then went to each of the three remaining diseased colonies, and, removing the queens, I introduced each of them to healthy colonies and allowed the diseased colonies to rear their own queens. The result was surprising in that the recovery of the diseased colonies was so prompt in all three cases. The old queens which were removed have had time to hatch out and mature a large amount of brood, and there is no indication of infection in any of the colonies to which they were given, which shows that the queens were not responsible for the trouble.

It is true that my investigations are not conclusive; but I am so sure that my conclusions are correct that I give them to the other members of the fraternity, especially those in the South, with request that they verify the same. I do not know just how long the colony should be without a laying queen in order to effect a cure, but apparently until all brood has been sealed, and the nurse bees have had time to get rid of all the food they have been preparing for the brood.

As above stated, in two cases in the past where I introduced queens received through the mails a cure was not effected until I again changed queens; and I attribute this to the fact that these queens must have begun laying before all of the old brood had been sealed. In no case where I have introduced a cell or allowed the colony to rear its own queen has it failed to effect a cure promptly.

I desire to say further that my observation is that it is not at all necessary to isolate the diseased colonies nor to remove them to a separate yard. In no case have I had colonies by the side of the affected colonies to become diseased. I have had my yard entirely well for two or three months at a time, as it is at present. I have never had the trouble occur the second time in the same colony, and have given combs of honey and pollen from diseased colonies to healthy colonies without ever having the healthy colony become infected.

Colquitt, Ga.

HIVES PROTECTED IN WINTER BY BUILDING PAPER TACKED TO A FRAMEWORK

BY M. J. KAUFMANN

I herewith enclose a photograph showing a hive and covering. The outside cover is a light framework covered with building paper. I tore the front out to show better the hive inside. During the winter there is just

A light framework covered with building paper as a protection against the wind in winter. The paper is torn away in front to show the hive inside.

a small opening in the front, an inch or two below the main entrance. This gives the bees plenty of ventilation and keeps out the sunlight. The principal object of the outer cover is to break any winds (even chaff hives occasionally will leak wind), and I find it saves the hive considerably against snow and dampness. Of course, a man running two or three hundred hives would not find this advantageous; but for the small beekeeper the slight trouble that he would have making the framework covering it would more than compensate him for the protection given the hives.

New York.

POSITION OF THE CLUSTER OF BEES WINTERED OUTDOORS

BY GEORGE SHIBER

In Dr. Miller's fifth Straw, p. 108, Feb. 15, he says: "While empty combs would be found below the cluster, the bees would never allow honey below the cluster." And, again, "But reasoning is not always safe." Even so. In the footnote, the editor says,

"We feel very sure we have had many cases like this where the combs of honey project below the cluster."

Mr. Editor, you have got the decision. In winter, are not bees always right up to the top of the frames? and if a space is made above the frames and under the quilt, don't they always cover the top of the frames? I do not recall a case where they did not. I will tell you what I observed last February. The 19th and 20th of that month were very warm, and the bees flew as in summer, so I took the chance and opened many colonies. I found hive after hive with honey in the bottom part of the combs—not only one or two, but a lot of them. In case of a great many I did not take out a frame if I could see the combs on the outside of the cluster with

sealed honey and the ends of the middle combs sealed.

One colony I opened and took out every comb. It had one of my choice queens. It was a magnificent stand of bees. Well, the four center combs had empty cells in the upper half, and sealed honey below. The two outside combs were still sealed solid—had not been touched. Yes, honey was below the cluster, for the bees were at the top of the frames. I opened a number of others that were in the same condition.

Yes, Dr. Miller, while I have a pretty warm feeling for you I shall have to take the editor's side of the argument, for you see I saw it, and it is still fresh in my mind. I have wintered a good many colonies in the cellar; and, so far as I have observed, your statement will hold true in regard to that mode of wintering—i. e., that honey will never be found below the cluster, but it will be found below the cluster when bees are wintered out of doors. Or let me say it this way—I saw a number of such cases last February.

Comb honey protected by a tin slide on each side of the section.

TIN COVERS FOR SENDING HONEY BY PARCEL POST

BY W. J. LEWIS

As an experiment we are sending you under separate cover, by parcel post, two sections of honey enclosed in our tin covers. One of these sections, among forty others, was exhibited at the Gulf States Fair at Mobile last fall, and was from there taken to Chicago and exhibited at the land show. It was then sent back to Citronelle, and, with about twenty others, inclosed with the tins, was put in a trunk with other baggage and sent to this city. If it reaches you in good condition I think it will be a fair test of our tin covers for supporting a section of honey while being handled. The tins can be put on or removed more easily by clamping them sidewise over the section than to attempt to slide on endwise.

This honey was produced in an improved Danzenbaker hive. We use a galvanized iron strip to rest the frames on instead of the wide cleats, for both supers and brood-chamber. We think this makes an ideal hive, as there is an air-shaft at each end of the hive, also a highway or passage for the bees to go and come. We also swing the extracting-frames and section-holders from the center. Our special frames, both brood and extracting, have seven-eighths top and bottom bars. The section-holders have the same width of top and bottom bars so as to cover the sections entirely. We have used the new frame and holder for two years.

We shall produce about 3000 sections at our Alabama place this year. Our apiary in this city consists of about sixty colonies; the bee-yard is illuminated with electric lights, and the hives stand on cement stands. We produce extracted here.

One correspondent tells how the price of honey can be raised six or eight cents per pound by advertising. Of this we feel certain. We get from six to ten cents more per section for our honey than the regular

price. Grocers will not handle other honey after once handling our product with its tin covers. Fancy honey ought to bring as much as fancy butter. We once thought the producers would some time get together, and, by advertising the merits and uses of honey, establish a better price; but we have about lost hope. Beekeepers are too widely separated for a concerted movement, and in the ranks are too many scientists and old fogies for united action.

St. Louis, Mo.

[The honey arrived in rather bad condition, the combs being cracked. However, we photographed one of the sections to show the protecting slide, an engraving of which appears herewith.—Ed.]

SHAKING COMBS OF A DISEASED COLONY

Reducing a Foul-broody Colony to a Few Combs which can be Shaken Quickly when the Treatment is Given

BY R. F. HOLTERMANN

It appears to me, unless my memory fails me, that in the many methods given for the treatment for foul brood (and if any do give it), little emphasis has been given to the best method of shaking bees from foul-broody colonies.

The object in shaking bees twice is to minimize the possibility that, at the close of the treatment, the bees may have any disease germs in the hive. The line of reasoning is that the bees are liable to fill their honey-sacs the first time they are shaken; that some diseased honey may be in the bees after the first cells in comb have been produced, and that they may have stored this honey in the comb where it is likely it will be fed to brood. Therefore another shake is given. Now, it might so happen that the operation may be repeated by the bees the second time; but the ratio of risk is reduced just to the extent that the amount

of diseased honey in the hive has been reduced.

Now, I am not going to pose as an expert in foul-brood matters, for I do not believe I ever had more than five colonies with the disease at one time in an apiary. I think I have had that; but I am very much afraid of it, and extremely anxious not to become any more familiar with it from a practical standpoint. In order not to be a menace to others, as well as not to spread it in my own apiary, I have read all that I thought worth reading about it, and have thought a good deal upon the subject.

The danger comes from the infected honey the bees take up and carry in their honey-sacs. Why, then, not do all one can to prevent them from getting any of this honey? Some combs, owing to propolis, and on account of the way they are built into the frames, and even attached to the sides of the hives, are so difficult to remove that the bees might almost get full honey-sacs before they are separated from their stores. Almost any hive, however, can be made more convenient for action. Where the colony does not occupy all the combs in the hive, all surplus combs can be removed—in fact, all that have no brood in them, or perhaps even more. The two outside combs can in any case be removed, and then when the bees do not expect it the beekeeper can go there with what help he can muster, smoke the bees if at all cross, or give little or no smoke if they are gentle (but better smoke the bees than work slowly). The combs can be seized quickly, the bees shaken off by every operator, and in that way the danger of transmission of the disease be overcome because the bees get little or no chance to fill themselves.

I am still a strong advocate of brimstoning the bees if there are only one or two diseased in a large apiary. This is not necessary; but I always feel that it is a safe way, and I am no stranger to that method of treatment, and under such circumstances I am in favor of burning the comb.

Brantford, Canada.

BEEKEEPING ON HILLCREST FRUIT FARM

BY S. H. BURTON

As bees are considered a necessary adjunct to a fruit-farm for the proper pollination of bloom, my first investment as soon as my berry plants and trees began to bloom was five colonies of bees. The bees were in eight-frame dovetailed hives, and were knocked down to me at a public sale at \$2.00 per stand.

They were purchased in October; and as

the honey-flow was practically over I at once moved them to my farm and prepared them for winter by removing the sections and filling the supers with leaves and chaff, first spreading a cloth over the brood-frames to prevent the packing from going down between the frames into the brood-chamber.

One colony was lost on account of being queenless. The other four wintered finely in an open shed with outside packing. These four colonies have never swarmed, although I have owned them for three years. However, this little experience gave me the "bee fever," and I have since built up my apiary by purchase, swarms, and increase, till now I have 24 colonies.

Up to July 1 the honey crop was immense, some colonies filling a super in ten days. The extended drouth for the past two months has shut off all sources of supply, and it now looks as though I might have to feed in order to winter through safely. Buckwheat was sown the middle of July, but it has been so dry that a great deal of the seed has never sprouted. However, a beeman is hard to down, so I still live in hopes of better luck ahead.

Having read about requeening and introducing, I decided to try my hand at introducing new blood into our apiary, and also see what I could do in the way of making artificial increase. Two queens were ordered, and the directions for introducing to a queenless colony were followed. The cage was slipped down between the frames, and was left 24 hours. Upon examination it was found that the bees had not released the queen, so she was turned loose, and ran down between the frames. The next day an inspection was made, and no queen was to be found.

With the second queen I had better success. Artificial increase was tried here; and instead of introducing the queen to the bees I did just the reverse—introduced the bees to the queen. A frame of honey was removed from a hive, and only about three dozen bees with it. This was placed in an empty hive with the rest of the frames containing full sheets of foundation. The entrance was closed, and left for two days. Then the cover was removed; and my queen, whose wings had been clipped, released. I then went to a strong colony having a full super of honey, and removed the super, bees and all, and placed on my hive containing the new queen. I left the entrance closed until the next morning. In 24 hours after opening the entrance those bees were carrying in pollen, and every thing was as orderly as could be. This, too, was during a drouth, and no robbing.

Washington, Ind.

A. P. Haberecht and family in their apiary in New South Wales, Australia.

BEEKEEPING IN NEW SOUTH WALES

BY A. P. HABERECHT

The conditions in the United States are altogether different from ours in the southern Revernian of New South Wales. Our average rainfall is 22 inches per annum. The coldest morning I can remember was 26 degrees F., and the warmest day 118 in the shade. Our produce is chiefly wheat and wool.

I am a builder by trade, and keep a few bees as a hobby as well as for profit. I have at present 70 colonies of bees, a few golden Italians, a few blacks, but mostly hybrids. The golden Italians I procured from H. L. Jones, Queensland. The queens which I raise myself go back in color every year; but as for honey-gatherers there seems to be no difference.

I am sending a picture of my apiary and honey-eaters. I have most of my bees in ten-frame Langstroth hives from one to three stories. I sell all my honey (extracted) in 60-lb. cans at the apiary. There is no sale for comb honey. I keep only one hive going with sections for my own use. I have exhibited extracted honey for six years, and have not yet been beaten. My locality is all right for quality, but no good for quantity. The best average I had for one season was 120 lbs. per colony; but the average for the last ten years would be about 30 lbs. per colony. I always leave about 30 lbs. of fall honey per colony, which has always been sufficient to see the bees through the winter, and to rear their brood.

The winter here lasts about three months (May, June, July); but on any calm and sunny day, even in the midst of winter, the bees will fly. About the first of September they will begin to gather pollen from cape-

weed, and swarm about the middle of October. Our honey is gathered chiefly from eucalyptus trees, which begin to bloom in September. Our locality has three species—the first one and the best, the yellow box (*Eucalyptus melliodora* A. Cum), then the red gum (*Eucalyptus rostrata* Schlecht), and, lastly, the gray box (*Eucalyptus hemiphylora*), which gives us our fall honey, and is dark in color, and

granulates quickly. The yellow box and red gum honey seldom granulate. Some of it never granulates. I have had samples since 1898, and they are just as I put them aside.

So far I have had only one case of foul brood. I at once sulphured the bees and burned the whole of the brood-nest with the bees, and I have never had any since. I kept bees in box hives about 20 years ago, on the Wimmera River, in Victoria, and lost 53 colonies out of 57 in a few weeks with foul brood.

In 1902, if I remember rightly, I lost in this locality 45 colonies out of 53 from what was called the "disappearing trick." Since that time I have not seen it.

Some seasons I have a good deal of spring dwindling, and sometimes a little paralysis; but the latter is not contagious here.

If any of your readers would care to exchange samples of honey I should be pleased to do so. I read some time ago that our eucalyptus trees are grown in some parts of America. I am sure they should flourish on your soils. Red-gum plantations should prove very profitable in America in the long run.

With reference to railway freight on honey in New South Wales, I interviewed the station master here, and he tells me he knows nothing about changing from B to A rate. His book says honey goes as B rate, minimum on ton (no difference in freight on comb or extracted honey); 50 miles, 10 shillings per ton; 100 miles, 18-10; 200 miles, £1-13-5; 300 miles, £2-3-10; 500 miles, £2-16-4; and 600 miles, £3-2-7.

NUMBERING OF HIVES.

The numbering of hives on their stands seems ridiculous. In the first place, one would want to have a number on every side

of the hive or else he would have to go to the side of the hive where the number is.

My arrangement is this: Ten hives in a row, always counting from left to right; and ten rows in each section (that is, 100 hives). I certainly have every hive numbered in my book; but in the apiary the position gives me the number at a glance, wherever I may be at the time. For example, a swarm is issuing from a hive, say the fifth in the fifth row, which must be 45; the brick on top of the hives gives me all the particulars I want as to the condition of the queen and hive, so I know every thing in a few seconds without moving one yard. I have had this arrangement ever since I began using frame hives. I have my hives on four pegs about 12 inches from the ground, and have them placed 10 feet by 20 feet, and a row of fruit-trees between, as you will see by the post card.

Henty, N. S. W., Australia.

IS SUGAR A WHOLESOME FOOD FOR BEES?

BY J. A. HEBERLE, B. S.

Practical beekeepers have always sounded a note of caution against feeding too much sugar. Of course the warning was not against feeding sugar for winter stores in a poor honey year, nor is there any harm in feeding a few pounds of sugar to each colony. I feed every year in September about four pounds of sugar to each colony at an apiary where the bees gather a little heather honey, and my bees always winter well.

The sugar is usually boiled. This was formerly done because ultramarine was used to make sugar appear whiter. By boiling, the ultramarine came on top and was skimmed off. I have no convenient place to boil the sugar. I use cold water to make the syrup—equal parts by measure of well-refined crystallized sugar and water. If it is late in the season, then a more concentrated syrup is used, as much as 7 parts of sugar to 4 parts of water by volume to this syrup. Hot water is needed to facilitate the solution.

Honey from honey-dew is not suitable for winter stores. Some of this capped honey should be taken out, and sufficient sugar fed or suitable honey given so the bees, while compelled to remain in the hive, can feed on the good honey or sugar. Honey from honey-dew invariably gives dysentery, and very often such a colony in our long severe winters is lost, or so weakened that it is scarcely worth the trouble. I recommend in poor seasons to take in early fall some capped honey from each

colony. Feed sugar instead, and give the capped honey in the spring as needed.

In our rough spring weather it is dangerous to supply feed in fluid form too early in spring. It entices the bees to fly out for water and pollen, and a large per cent never reach home again. If the lacking food is supplied with capped honey-combs the bees are not so excited nor so much stimulated, and at the beginning of the honey-flow are usually more populous, and consequently bring more surplus. Colonies not stimulated seem to conserve their energies, and use them later to better advantage. Stimulating in the latter part of spring when the inconstant weather has lost part of its danger may be advantageous. Great care, however, must always be exercised when stimulative feeding in spring is practiced. The warning against sugar feeding was for those beekeepers who take all the honey they can from the bees and feed sugar. These mercenary beekeepers think they are profiting by this robbing system, but they are mistaken. They have considerable work, and but little gain. They do harm to their bees and lessen the chance for a good crop of honey next season, because the colonies so robbed do not prosper as well in spring on the sugar, and can not make use of the early honey-flow to the same advantage as the more populous colonies that had plenty of honey during brood-rearing time.

Dr. U. Kramer, of Zurich, wrote an interesting article on "The Physiological Effect of Sugar-feeding." By analysis it was determined that sugar honey (*i. e.*, sugar fed to the bees and extracted) contained practically as much nitrogen as honey. Of course, the ethereal oils and other subtle substances peculiar to honey are not present, and the inversion is not complete. Sugar honey from the uncapped cells showed 0.28 per cent of nitrogen; the capped sugar honey showed 0.36 per cent of nitrogen. Sugar is a hydro-carbon, and contains no nitrogen. Dr. Kramer deduces, therefore, that the bees supply albumen from their body while inverting the sugar. If that is so, there can be no question but that feeding great quantities of sugar must be harmful to the bees. It must weaken their vitality and make them more susceptible to disease.

HOW LONGEVITY IS INFLUENCED.

To lessen the vitality means to shorten their life, while longevity of the bee is the secret of success in beekeeping. It should be the ideal of the beekeeper to produce by careful selection bees that have *great vitality*. Such bees resist diseases better, and bring the most surplus. During spring the

brood-nest can be increased only in proportion to the bees present in the colony. If the bees of a colony during the busy season live seven weeks instead of six, that colony will become populous providing the queen lays an equal number of eggs sooner than the colony whose bees live only six weeks, and would bring in much more surplus. By selection bees have been produced, not only of splendid color, but also of great fertility. Great fertility alone does not mean great surplus unless the offspring have great vitality.

Longevity is a consummation devoutly to be wished. If the beekeepers, especially the breeders, strive to produce queens whose progeny are especially hardy they will succeed, just as they have succeeded with fine color and great fertility. The trouble is to know the queen whose progeny is especially hardy. If beekeepers once decide to pay especial attention to longevity they will find ways that will permit them approximately to judge of this desirable quality. If a colony has a very fertile queen, and is populous, yet does not bring in surplus correspondingly, one may infer that the fielders are not in the right proportion to the nurses. Unless there are other conditions that account for the deficiency, that would mean that the fielders do not live long enough. On account of the fertility of the queen, the colony is always populous, consumes great quantities of honey to feed the larvæ, but, having fewer fielders than a colony whose queen is equally prolific, but whose descendants live longer, is short in surplus.

By comparison of two colonies of about equally fertile queens but great difference in vitality, the colony of greater vitality would be more populous mornings and evenings. A colony that does not seem very populous during the day, and the fertility of the queen only medium, but whose surplus compares favorably with the best, that will be a colony whose bees probably have that longevity that the up-to-date beekeeper should wish. We know in a general way that bees during the busy season live about six weeks, while bees hatched in August or September live about eight months.

To accomplish much by selection in a short time, it is essential to select carefully the colonies from which queens are reared. Equal attention should be paid to the selection of colonies whose drones are to make the queens. A choice colony, only the best is good enough, should be set up in a place far away from any apiary and from the woods where wild bees are—say one mile (a greater distance would be preferable), and the queens to be mated should be

brought there. The colony should have opportunity to rear a great number of drones; and if the honey-flow is meager, liquid honey mixed with an equal volume of water should be fed for the purpose of stimulation. Under such conditions a high percentage of queens would be mated pure, and transmit to their progeny with much greater certainty the good qualities of both parents. We may often note that some colonies are much quicker in detecting distant sources of nectar. This is also a quality that deserves the special attention of the breeder.

I have noticed that some beekeepers in America advise feeding only cane sugar, claiming that beet sugar is not wholesome for bees. I think this warning is not justified. All sugar we use on the table is cane sugar—that is its proper chemical name, regardless of its derivation—and is in all cases just the same, be it from the sugar-beet, sorghum, sugar-cane, or the maple tree. In good or *well-refined* sugar there is barely enough of other substances so that its derivation may be determined by the most delicate and refined methods of modern science; but the ordinary mortal can find no difference.

In Germany we use sugar from the sugar-beet exclusively. I have never heard of a case where any undesirable effects had been noticed by feeding to bees well-refined sugar from the sugar-beet. The tendency of degeneration of the bees through feeding large quantities of sugar will be the same whether the sugar is derived from the sugar-beet or the sugar-cane. Alcohol is the same, whether it be from corn, barley, or potatoes. This article applies especially to conditions prevailing here in Bavaria.

Markt Oberdorf, Bavaria, Germany.

THE "MOVIES" AND BEEKEEPING

BY LOUIS SCHOLL

Continued from page 709.

for advertising the beekeepers' products carried out.

Of course, I do not mean to say that such a film should be straight-out advertising in its make-up, but that the scenes would be interesting moving-picture-show stuff, and so interesting that they will attract attention. Then, indirectly, the advertising feature of these pictures should come out of strong suggestions incorporated in various ways throughout the film. The titles to the different scenes should be suggestive as well as explanatory, and the pictures should be such as to create the desire that we are after. For instance, if the matter of honey can be kept uppermost in the minds of the

spectators by showing the honey in its various shapes and forms, perhaps best in the combs as they are handled from the hive, etc., honey handled in the store, a person purchasing or admiring a package of the clear liquid honey, or the pure white comb honey, and shelves of honey in nice glass, as well as exhibits at fairs, with large pyramids of honey in glass, or great piles of it in the comb, would help out. But better still, it seems to me, would be such pictures as actually show the honey being used and eaten at the table, with nice brown biscuit or hot cakes, or somebody giving nice bits of white comb honey to some rosy-cheeked children in place of pieces of candy. Honey could be displayed in many other interesting as well as suggestive ways.

It is true that not every detail need actually be shown in a picture film to place before the spectators a whole story about honey and the value of good honey. Just as one goes to see a great play, either in a theater or a reproduction of it in a moving-picture show, because he has read a book of the story of the play, so a complete picture story of honey production and honey for food could be given which would create, at the same time, a demand for this product.

FIELD NOTES FROM MINNESOTA

BY J. ALF. HOLMBERG
Apiary Inspector

The results of the treatment of bee diseases throughout the State have been very gratifying this year, and it looks to me now as though we were the masters of the situation so far as a cure is concerned. I am pleased to say that I have not been able to find any European foul brood this season, and we can keep it so if we can have the co-operation of every beekeeper. I have found several places that were stricken with sac brood. The Bureau of Entomology at Washington does not advise treating this disease; but where there are not too many colonies I think it a good thing. In one instance I treated a colony where sac brood existed, and it produced 75 lbs. of honey the same season.

So much has been said and written on foul brood that I hardly deem it worth while to enter into a description of this disease in this writing; I shall, however, endeavor to state in my annual report every thing of importance regarding this disease.

Allow me to say that I will advise that no chances be taken at all if one desires the quickest way out. This seems to be the greatest difficulty among so many beekeepers that have affected apiaries, and if they

would just try to keep every thing clean after treating, it would mean more to the bee industry than I could mention at this time. On one occasion where I inspected an apiary I found some hives with American foul brood. The owner helping me in this work wore gloves. When the work was completed in this yard we were to inspect another yard of his close by. We went there; and if I had not stopped him he would have used the same gloves and tools without disinfecting them. I afterward found out that he had done this before, and, of course, had spread the disease himself. This, of course, was carelessness on his part; and so many seem to think this is such a small matter that it doesn't count: but when a person is dealing with a contagious disease he can not be too careful.

In hiving stray swarms, unless one is positive that they are from healthy colonies, I advise putting on empty frames or starters. Later, these can be replaced with full sheets of foundation. By doing this the bees will use the honey they had with them for the secretion of wax.

St. Paul, Minn.

Screen for Keeping Mice from a Hive

I had a couple of hives into which mice had found their way. They did a whole lot of damage to the bees before I could find out what the trouble was. Whenever one sees at the entrance an unusual amount of bitten-up bees and larger pieces of comb, wax, or wax mixed with packings, he may surely make up his mind that there is something wrong inside the hive.

If the weather permits, and the bees are flying, open the hive, and a mouse or something else will be found in the hive. Unless one is careful to catch the mouse it will hide between the frames. If the weather is too cold, and the bees are not flying, one may catch the mouse with a small trap on the outside of the entrance.

To avoid all this trouble, the very best thing I have found is to use a strip of screen (quarter-inch mesh), and fit that in front of the entrance. That will not interfere with the bees going out and in, and will keep out the mice. I get pieces of screen (scrap) at a carpenter's shop or hardware store. I cut them about 3 inches wide, and the length of the entrance of the hive, and bend them at a right angle so they look like a small trough. Then I lay them in front of the entrance. The one side will lie down flat on the bottom-board, and the other side stands up-right against the entrance.

The Dalles, Ore., Jan. 11. JOHN PASHEK.

Another Successful Introduction by the Smoke Plan

I want to tell of my success in smoking in queens. I have used the plan advocated by A. C. Miller, with good success. I had two colonies that were queenless for two months. I tried to introduce queens by the cage method but failed. Then I ordered two more queens, and this time I followed Mr. Miller's plan, and I succeeded. The next day after introducing the queens I found they were laying. It is certainly a time-saving method, and I prefer it to the cage plan.

Sugarcreek, Ohio., Aug. 30. D. W. MILLER.

Heads of Grain from Different Fields

Bees Essential to Fruit-growing; How many Colonies to a Given Number of Trees

We are novices as yet about bees and their care. We know, however, that the bee is an important factor in orchards, and because of such we contemplate making a very important incidental department of bees in our industry at Grand Isle, Vt. We can buy plenty of bees about here. I suppose they are common bees. Some say "black bees." Our notion is to start with enough swarms next spring to serve our 15 acres of old large trees and to let them multiply as fast as they will in contemplation of the 10,000 young trees set in 1912-13. We will have about 150 acres of orchard, and our present notion is that a sufficient number of bees should be stationed near every section of the orchard so that in case of cold or rainy weather they need not work far. I don't know the number of colonies necessary for 10,000 young apple, plum, pear, and cherry trees, nor do I know how many swarms will secure their honey from a given center or quarters; or in other words, the territory or zone necessary per 100 colonies of bees at other times than blossoming time of fruit trees.

EASTERN FRUIT AND NUT ORCHARD CO.,
CLARENCE J. FERGUSON, Manager.

Burlington, Vt., Sept. 9.

[We refer you to GLEANINGS, August 15th issue, p. 562. You will see there that the Repp Bros., who are large growers of fruit, especially apples, regard the presence of bees as very important. We have one large orchard about ten miles north of us, 40 acres, and the grower there requested us to put upon the place some fifty or sixty colonies of bees. He secured a very fine crop of 16,000 bushels of apples, and when we saw him a few days ago, he said he attributed a good deal of this to the presence of large numbers of bees. He stated that he would want something like a hundred colonies of bees next year, as he expected to have one or two more orchards in the vicinity. We also refer you to GLEANINGS for July 15, p. 478, for a remarkable testimony on the value of bees as pollinators. See also our booklet, "Bees and Fruit." You will find much more matter on this same subject in the A B C and X Y Z of Bee Culture under head of Fruit Blossoms, and also under Pollen.]

Just how many bees may be necessary for a given number of trees, we are not able to give you definite information; but our neighbor ten miles north of us thought that he would need about forty or fifty colonies for 40 acres of apple trees. Your plan is correct, to start a small apiary to take care of your 15 acres of old trees, and then increase the number gradually up to take care of the ten thousand young trees that you set in 1912.

You will find that the bee business is a profitable side line in connection with your fruit-growing because you will be the busiest with your bees just at a time when the work with the fruit trees will be at the least. During the cold weather and early spring the trees will need to be pruned and sprayed, and at that time the bees require very little attention. When the main honey crop comes on, say in the months of July and August, or rather the months of June and July, you will not need to be very busy with your trees, and consequently can give your whole attention to the bees. To our notion a combination of bees and fruit-growing is most excellent.

In putting bees in an orchard, it is desirable to scatter them, a few colonies here and a few colonies there. The idea is to get the bees arranged so they do not have to fly very far on cool or rainy days. Bees will go a short distance, and when they strike the cold air will go back to their hives, and for that reason it is desirable to have the colonies pretty well

scattered throughout the orchard. This makes a great deal of travel for the apiarist between the hives, but at the same time you get a much better distribution of the work of the bees.—ED.]

How to Winter Three-frame Nuclei, and Carry Over a Surplus of Queens

Can you tell me of any method that is fairly reliable for wintering nuclei of two to three frames in the cellar?

Chaffee, N. Y., Sept. 18.

A. J. O'DELL.

[It will be perfectly practicable for you to winter three-frame nuclei in a cellar, providing you have the right conditions. The temperature must not go below 40 degrees nor much above 50. The bees will stand 60 degrees providing you have a large amount of ventilation. The cellar must be absolutely dark, and it should be reasonably dry. If the temperature hovers around about 38 and 40, 41 and 42, and is damp, you will probably lose a large part of the bees in these nucleus boxes. If, however, you can keep the temperature at about 45 to 50, with a dry atmosphere and a large amount of ventilation, without bringing in light, you will get fairly good results in wintering. Put these nuclei as close together as possible, to conserve heat. You will need to watch the temperature very carefully. It might be wise to put in the cellar a small drum stove, the smallest one you can. Connect it with a chimney; and when the temperature goes below 45, build a very little fire. This will change the air somewhat, and at the same time bring up the temperature and keep the bees quiet. If your cellar is such that it goes up to 60 degrees, and you can't hold it down, the bees will fly out on the cellar bottom and you will lose a large number of them, possibly all of them, in that way. The only thing to do is to ventilate, leave the cellar door open at night, and close it during the day. It is desirable, however, to have fresh air going into the cellar *all the time, if possible*. If, however, you can maintain a temperature of about 45 to 50 without very much variation, you will not need a great deal of ventilation, although we always think it advisable to have the cellar dry with plenty of air if possible. If you could have an arrangement whereby you could put the bees in a room by themselves, with an opening that will communicate with one or two other rooms under the building, it will make the ventilation very much better. It is not possible to winter a large number of bees in a small room unless there is a large amount of ventilation. We can not emphasize that point too strongly.—ED.]

Does a Taste for Honey Have to be Acquired?

Mr. Root:—In your issue for Sept. 15, page 639, you have a short article headed "Honey a Concentrated Food," etc. On page 637 is an article by Doolittle, who says little honey would be eaten if it were not for its flavor, as the same amount of nutriment could be more cheaply obtained by buying sugar and making a syrup. I believe the taste for honey has to be acquired; and if Doolittle is correct, sugar syrup or a good maple-sugar syrup is fully as desirable, and far less trouble.

C. V. S. REMINGTON.

Fall River, Mass., Sept. 17.

[We can not quite agree with you that a taste for honey has to be acquired. If that were a fact, there would be very little honey consumed. This is true, however: Flavors that we enjoyed in childhood we continue to enjoy during our lifetime. We have noticed this, that persons who have been brought up in York State, who are familiar with the flavor of buckwheat honey, usually like it, even after they have come up to middle life and past. Those who

have been brought up in the one or two localities where maple syrup is produced are very fond of that flavor because they were used to it in childhood. Those who are accustomed to the flavor of clover honey, of basswood honey, or of alfalfa, continue to like those flavors. A really good table honey, like clover, basswood, or alfalfa, or even mountain sage, will create its own demand. In other words, the consuming public does not have to be educated to like them. It is a case of love at first sight.—Ed.]

Should Foundation in Sections be Placed with the Parallel Sides of the Cells Horizontal or Vertical?

I should like to make a few remarks in regard to the cover picture of the July 1st issue. There is a fault in all foundation that is made for oblong or deep sections which should be remedied. It should hang from the top of the section the way it comes from the mill, not crosswise. Notice the waves on every section. There would be none of these if foundation were hung the other way. There would also be less sag.

Then, too, foundation would not drop so easily when hauled over the road. But the most important point is that the honey has a much nicer appearance. Just compare two sections, one of each way, and see. Who put Nos. 10, 12, 13, 15, and 16 upside down when they took the picture? Notice the reverse position of the curves.

I have used 800 supers with wire fences and bee-way sections for three seasons, and the per cent of burr-combs is small.

East Syracuse, N. Y., Sept. 20. F. W. LESSER.

[Some years ago we made a series of experiments with the comb foundation in sections, placed both ways—that is, a part of the sections contained starters in which two parallel sides of the cells were vertical and the rest of the sections contained foundation having two parallel sides horizontal. At the time, we could see very little difference in regard to the amount of sag. Furthermore, beekeepers disagree in their opinions in regard to the matter. Some cut their starters one way of the sheet, and others the other way. Before going further we should add at this point that natural comb is usually built with two parallel sides of the cell vertical, but occasionally the bees build the comb the other way.

It is practically impossible to make a foundation-mill with the cells cut in such a way that two parallel walls of the cell will be parallel to the long edge of the sheet as it runs through the mill. In other words, two parallel sides must be crosswise of the sheet as it runs through the mill—that is, parallel with the rolls of the mill. When making brood foundation it is customary to have the sheet of wax as wide as the brood-frame is deep, and then after running through the mill the wax is cut into lengths corresponding to the length of the brood-frames or a little less. With this manner of cutting, two parallel walls of the cells are vertical, corresponding to most natural-built comb. The super foundation, on the other hand, while run through the mill in the same way, is almost always cut just the opposite; that is, with two parallel sides of the cells horizontal. The reason for this is that it is more convenient to cut it in this way, although, of course, the beekeeper may cut it the other way if he prefers. The foundation in the sections shown in the cover picture of the July 1st issue happened to have been cut with two parallel sides vertical, as in case of brood foundation, whereas the customary plan is to have foundation cut the other way, which is in accordance with our correspondent's idea, if we understand him correctly. We formerly cut starters for oblong sections with two parallel sides vertical, the same as shown in the cover picture referred to; but something over a year ago we began cutting starters for the oblong sections the other way, just as in the case of square sections.

In this connection we should like to inquire wheth-

er any one else has done any experimenting along this line—that is, with foundation hanging both ways in sections. If so, we should like to hear the results. To be conclusive, the tests should be made under like circumstances and conditions so far as possible.

Our correspondent has an observing eye. The sections shown in the cover picture of the July 1st issue were piled up on the table. On account of the fact that they were not quite square a few of them had to be turned upside down to make the rows straight. This accounts for Nos. 10, 12, 13, 15, and 16 being upside down.

We are glad to have the good report of wire fences. Mr. Vernon Burt has secured some of the nicest comb honey this year that we have ever seen, with this same sort of equipment. Apparently the danger of bees attaching the combs to the wire is not as great as was first feared.—Ed.]

Should Supers Containing Brood be Removed in the Fall?

Last spring I purchased four colonies of bees. Colony No. 1 filled two supers with fine white-clover honey; but the last super they have filled with brood and young bees. Shall I leave the super on through the winter or not? If left on, what will be the result next spring? Do you advise using two brood-chambers for strong colonies? Colonies 2, 3, and 4 have the supers about half full of honey, and the brood chamber full of brood and honey. If I remove the supers, will the brood-chamber have enough supplies to carry the bees through the winter? or will it be best to leave the supers with honey in them on through the winter? I am using Langstroth ten frame hives. When the frames in the brood-chamber have honey and young bees, can the frames be put in an extractor and the honey be extracted without injury to the young brood, and then replace the frames to give more room for the queen to lay eggs?

Port Gibson, Miss., Sept. 8.

B. F. MINNIS.

[It would be questionable practice to attempt to remove this super containing brood, at this time as you will seriously weaken the colony and take away young bees which you will need next spring to keep up the strength of the colony. Under the circumstances the colony may be wintered in the story-and-a-half brood-chamber. While the weather is still fairly warm, perhaps it would be well to locate this super on the bottom-board and put the full-depth brood-chamber on top. Some time in the early spring, before the queen has started very much brood, you can remove this super from under the brood-chamber, thus getting the queen and bees on one set of brood-combs again.

We can hardly say from the description you give whether the brood-combs will contain enough honey. About the only way is to make an examination to see that all combs contain some honey; and the outside combs should be nearly solid with honey, perhaps two combs on each side. If there is not this much in the hive, feed a thick syrup in October, made by mixing two parts of granulated sugar to one of water until there are enough stores.

You can extract honey from combs containing sealed brood; but if there is any young unsealed brood this will all be thrown out with the honey. Therefore no attempt should be made to extract from combs containing unsealed brood.—Ed.]

Shipping Extracted Honey by Parcel Post

I have just read Dr. Moody's article, Sept. 15, p. 653, and should like to mention a few facts pertaining thereto. I am a clerk in the parcel-post department of the Cincinnati postoffice, also a beekeeper on a limited scale (having but 14 colonies), and am naturally in a position to observe a great many things as regards shipping the endless variety

of merchandise from practically every section of the country.

About two weeks ago two 10-lb. pails of extracted honey, which had been shipped from a small town in Kentucky to a party in this city, were received in our local office, in a deplorable condition. Each can, of the friction-top variety, was securely fastened in a sort of substantial wooden framework, but packed in such a way as to leave the rims of the cans extending beyond. In transit both had evidently received a blow or jar on the rim, causing same to spring just a trifle, but sufficient however to cause an almost invisible gap between the cover and the rim proper, resulting in about half the contents of the cans leaking out and completely daubing up every piece of mail in that particular sack. The public in general does not realize the hard jolts these mail-sacks receive in being transferred from one train to another, and in being loaded on and off the mail-wagons.

Only a few days ago several pounds of grapes packed in a flimsy pasteboard box were received in a state of "mush," the package having been flattened completely.

A 5-lb. can of fine country butter received the same treatment. When a 20-lb. piece of machinery comes in violent contact with a fragile article or package, something is going to happen.

In order to ship honey safely by parcel post it is necessary to enclose it in a stout wooden box with plenty of packing to take up the jar. Our parcel-post service is being constantly improved; it being still in its infancy, too much can not be expected at the start; but in due time the many problems will be worked out, and fragile articles shipped with perfect safety.

Cincinnati, Ohio, Sept. 18.

ALBIN PLATZ.

Why Swarms do not Carry Foul Brood

In a footnote in *Stray Straws*, p. 633, Sept. 15, you say that "it is generally understood that swarms do not carry foul brood." Please tell us why; or how it is possible for them to do otherwise than carry it when they leave the parent hive loaded with infected honey? I once had an infected colony swarm, and I hived them on full sheets of foundation; placed it on the old stand, put on a queen-excluder, and placed the partly filled super of extracting-combs from the parent colony over it. By so doing I gave them a place to store their loads of infected honey; and as nectar was coming in freely this honey was soon covered up; and later, when it was well capped, I removed it with an escape-board and extracted it and melted up the combs. The swarm has never shown any sign of foul brood since. I felt certain that I had saved them from it only by giving them empty combs above the excluder. I imagine my prime swarm would soon draw out the foundation sufficiently to store some of the honey brought with them. It seems to me like taking a big chance. We should like to know more about the subject from some of you fellows who probably are in a position to "put us right."

J. E. BATTRAM.

St. Thomas, Ont., Can., Sept. 22.

[Bees shaken from a diseased hive into a clean hive on frames of foundation will not carry the disease with them, as a rule. They will consume what honey they may have in their honey-sacs in drawing out of the foundation. However, to be doubly sure, Mr. McEvoy advised the use of two sets of foundation and a second shaking. This is a great deal of work, and it is very rare indeed that a second shaking is ever necessary; that is to say, one drawing-out of foundation seems to suffice for all practical purposes. This plan, which is so generally in use all over the United States and Canada, and to a great extent in Europe, is really founded on what is known as the Quinby treatment. He originally shook his bees from diseased hives into a clean

hive and caused them to build new combs. In that early day there was no such thing known as comb foundation; but the bees were obliged to build their own natural combs. This necessarily compelled them to use up any diseased honey that they might have in their sacs in the comb-building. If the Quinby treatment or the foundation plan of treatment is a success it would naturally follow that a swarm of bees leaving a diseased hive or diseased combs would not carry the disease with it, for it would be compelled to carry out automatically what is known as the Quinby treatment of cure; but if such a swarm of bees should go into a bee-tree that already had disease, or should occupy combs that had been infected by foul brood, of course the disease would appear again.—Ed.]

From 25 to 90 Colonies, and 2 Tons of Honey; Crops Sold at 25 Cts. per Pound

I had 55 colonies, spring count, and have increased 35, and have two tons of honey so far. This honey was gathered during parts of April and May this year. I thought I was amply prepared for the honey-flow, but used every thing in the way of hives and supers I had, and think I could have doubled my crop had I had supers sufficient. Nectar came from wild flowers mainly; but there was a two-acre patch of buckwheat half a mile away which makes the honey a light amber. I produce both bulk comb and extracted. I have just discovered that I am within only a few miles of thousands of acres of tupelo gum which is absolutely unoccupied by bees. I have a splendid market for all the honey I can produce, at 25 cts. per lb. for bulk comb and 20 cts. for extracted. So far I have visited only the office buildings and merchants at their places of business. Trade is all retail, 5 and 10 lb. lots; no house-to-house soliciting (at residences) so far. Nearly all deliveries are made on the spot at the time the order is taken. I don't have to deliver at a residence. My bees are all on a 25-ft. town lot on which is also a house and barn.

Nederland, Tex., June 19.

J. H. WEEKS.

Condition of Nuclei to which the Virgins were Introduced

I should like to know whether there were eggs and larvae present in colonies where those "old virgins" were introduced (editorial, Sept. 1, p. 594). Will you please let me know the condition existing in nuclei or colony at the time of introducing? how long queenless? any supersedures yet? any cells at time of introducing?

Corinne, Utah, Sept. 5. A. B. DICKINSON.

[Mr. Marchant replies as follows:—Ed.]

"I have tried introducing old virgins to colonies and nuclei in various circumstances, but I find that they will be more successfully accepted in colonies or nuclei that have been queenless not over 48 hours. If cells have been started and not removed, the results are not very satisfactory. If the cells are removed several hours before the virgins are run in, they are usually accepted all right. So far I have found no supersedure, and do not believe there will be any, for I am sure that, where the old virgins are run in, they will make as good queens as any, unless the virgins in question are very old indeed. Virgins five or six days old are all right. Some of my best queens were old virgins when introduced."

Good Season for Colorado

This was a good honey season here; about 12 cars, total crop. My crop was 200 cases comb, 8000 lbs. bulk comb, and 25,000 extracted; mostly sold except the last car of comb honey.

Rocky Ford, Colo., Sept. 11. BERT W. HOPPER.

Our Homes

A. I. Root

Pure religion and undefiled before our God and Father is this, to visit the fatherless and widows in their affliction, and to keep himself unspotted from the world.—JAMES 1:27.

I clip the following from the *Cleveland Plain Dealer*:

When one of the Atlantic liners docked at New York, June 16, it bore among other passengers in the steerage a woman and a little child, on their way to join the husband and father in America—the land where one always has enough to eat, and where there are no nobles and landlords to whom one must bow very low.

Father had saved enough for a passage for mother, the family was to be reunited and all would be well. The father was Constantine Michalski. The newcomers were Antonia, his wife, and three-year-old Maria, bound for Cleveland.

They arrived. Eight days later Constantine was killed in an accident. Mother and child were left penniless.

To-day, because the two have become public charges, they are to be placed on a New York train by immigration officials and will be deported.

I suppose our emigration laws are wise, and almost a necessity; but when carried out to the very letter in some cases they work hardship and trouble. This good woman and her three-year-old daughter in one brief hour had all her dreams of the New World shattered, and through no fault of their own so far as we know; and yet she is pushed away back across the ocean, perhaps to be dropped without friends or means. I was wondering why the W. C. T. U. or the Salvation Army or some other worthy society could not have found a place for this woman where she could support herself and child, especially when there is such an increasing demand for help of all kinds. It will cost quite a little sum to send her back to her old home. Now, could not this sum have been employed in placing her where she could do good and receive good? Can any of our readers tell me if there is any such institution located near where emigrants land?

The above paves the way in a vivid manner for something else that is just coming up before our American people. Read the following, which I clip from the *Illinois Issue*:

MISPLACED PERSONAL LIBERTY.

Why deprive paupers, lunatics, idiots, and criminals of the personal liberty of landing upon our shores, and grant saloon-keepers the personal liberty of manufacturing them at home?

What do you think about it, friends? While our nation is thus treating that poor woman and her child described in the above, is it really true that the saloon business, at least indirectly, is kept going and encouraged in its work of *manufacturing* paupers, lunatics, idiots, and criminals? Answer the question yourself. If you are in

dry territory where no saloons exist, thank God; and after you have thanked him for your own environment, read the news coming from all the great cities or any small town where saloons are tolerated, and then wake up and do something. Mr. Rutledge, the great temperance orator, told us a few days ago that several important temperance measures had been lost, some of them here in Ohio, because only *one voter in seven* voted at all; and in our recent crusade for woman suffrage, only one man in three voted either for or against. They just stayed at home and attended to what they considered to be more important business.

But there is going to be an awakening, thank God, and an awakening is now going on all over this whole wide world, and God's kingdom is coming.

With the above as an introduction I wish to submit to you another important matter concerning which the world is (thank God) also waking up. In our issue for September 15 I spoke about dentistry and what it is doing for the health of our people. A good friend of mine has sent me a beautiful little magazine entitled *Oral Hygiene*, a journal for dentists; and after briefly turning over its pages I devoutly wished it could be read by every man, woman, and child. Here is the letter that called my attention to the magazine:

Cowan, Carr & Lauderdale,
Producers of
HONEY
Geneseo, New York

My dear Sir:—By this mail I am sending you a copy of *Oral Hygiene*, and desire to draw your attention to the editorial by Dr. Hunt, on page 226. It may be a little too plain-spoken for a lay publication such as *GLEANINGS*, but I think your perusal of the article will possibly be of assistance to you in some of your future writing; and at any rate I am glad to introduce to you another courageous man, "Dr. Hunt," who is not afraid to say what he knows is true.

Geneseo, N. Y., Sept. 13.

J. W. COWAN.

Below is the article referred to, which I clip from said magazine:

Every child has the sacred and inalienable right to be born free from disease, free from deformity, and with pure blood. The State which does not do its full duty in the matter of securing these sacred and inalienable rights to all children is deficient and delinquent in its duties.

From 70 to 80 per cent of abdominal and pelvic surgical operations on women are the result of gonorrheal infection transmitted by infected and supposedly cured husbands.

Gonorrhea permanently maims one in a hundred and kills one in two hundred.

It is a shame to our civilization, a fearful sin of omission on the part of the State, that not less than five hundred noble and pure women are inoculated annually in Indiana with loathsome diseases, and the law is silent.

The venereal diseases are social assassins. They cause deterioration of the race.

Twenty-eight per cent of insanity is caused by syphilis. The government spends scores of thousands of dollars, and establishes rigid inspections to prevent the spread of the coitus disease (animal syphilis) of the horse, but the infection of the horrid syphilis that entails endless misery on scores of thousands of innocent women and children may be disseminated by anybody, and is being disseminated by scores of persons in this country, unchecked, under the protection of the "personal liberty" flag. Alas, that so little regard is had for the loss of liberty of infected women and children.

Marriage of a man with venereal disease is not only a violation of decency and love; it is a hideous and dastardly crime. And, let not the State be *particeps criminis* by failure to enact restrictive measures.

There exists a test for syphilis so simple that there can be no more objection on any sentimental ground to it than to vaccination.

A child born with syphilis will rarely come to useful manhood or womanhood. Such are almost certain to become dependents and delinquents, and so a burden to society.

To permit the procreation of the unfit is a violation of all the laws of economy. That State is sadly incompetent which permits lepers to marry and procreate, and then builds homes for the infected progeny.

Let a man poison a pure woman with arsenic, and the State takes him severely in hand without hesitation or care of expense. Let him poison her pure body with the leprosy of syphilis or gonorrhea, and the State is silent.

Prudery, the cause of the silence, is not a virtue. It is a mock-modesty. It is to virtue as nastiness is to purity. Yet it holds us back from steps necessary to secure the sacred and inalienable right of children to be born free from disease.

Our readers will recall that I have taken up this matter several times before; and I hardly need inform you that the saloon business is at the bottom of the whole work. Where saloons are banished, houses of ill fame soon disappear. They can not live without the curse of intoxicants. The people who make money out of this traffic are fighting woman suffrage tooth and nail. They well know that if women handle affairs, innocent mothers along this line will be a thing of the past; and if the mothers could have their say in the matter it is very certain that no more children would be cursed for life, because their fathers first got drunk and then followed after the "strange woman."

WAS ALL CREATION MADE SOLELY FOR MAN'S
BENEFIT.

Mr. Root:—Under the heading Special Notices, in a letter from a correspondent, I notice this paragraph:

"I believe that God placed every thing here to be of use to man in some way or other, but only we are so blind we don't catch on to all of them."

Now, I have no disposition to find fault with the writer of this paragraph; but I wish to call attention to what I consider a serious mistake often made by mankind in assuming that, because we are the dominant, and, because of our intellect, the most powerful visible creature inhabiting our earth, that the earth and all that is therein, and the sea and all

that is therein, and the air and all that is therein, are made for man's peculiar benefit. I am sure that man can be benefited and learn something from all creatures, but that is not the purpose of their creation. I can conceive of no reason for man's being placed on this earth other than that he might have opportunity for growth and development, and the acquirement of knowledge, power, and self-control. To me, life on this earth is as a great school with wonderful opportunities; and I believe that all life on this globe, however far below us it may be in development, is placed here for the same purpose, that it may develop, unfold, and gain experience. Because we form the highest class in this great university, we should not conclude that all the lower grades are placed here for our benefit. We should rather strive to be of assistance to the lower classes by showing kindness and helpfulness in all possible ways. I fear the idea that all things are created for our benefit is the cause of much needless cruelty to helpless dumb animals.

May God help us to see and realize that all life is one, and that we are no better in his sight, and no more objects of his loving care than the most lowly objects of creation.

Louisville, Ky., Sept. 30.

W. C. FURNAS.

SHOTS THAT WEIGH 1000 LBS. EACH, ETC.; SEE
PAGE 197, MARCH 15.

I am still on the U. S. S. Arkansas, and have the gyro compass. We just came in after target practice, where we broke the world's record with twelve-inch guns, firing six shots and making six hits in fifty-seven seconds. You can imagine how fast the boys worked handling projectiles weighing nearly one thousand pounds each, in such a short time. We are all proud of our record.

I was promoted to-day to "electrician, first class," which pays \$55.00 a month—an increase of \$11.00 a month.

We are going to Naples, Italy, Oct. 25. I expect to go to Rome and see the sights, which I hear are very interesting.

By the way, I received GLEANINGS this evening, when I happened to glance at the trouble with your teeth. That is one thing the navy requires most strongly; and, thanks to sister Donna, who used to scold me about mine, I finally got to noticing people's teeth. I also "noticed" yours when I was there, and often wondered if you realized what a difference it makes when a person gets up in the morning. That is one thing most people give little attention to, and yet it is one of the most important things.

HOMER ROOT.

U. S. S. Arkansas, Brooklyn, N. Y., Sept. 18.

Dear nephew, I am glad to hear of your promotion, and I am glad, too, to see you take your old uncle to task for carelessness in his personal habits; but just a word about those 1000-lb. projectiles. I am, as a rule, glad to note progress and efficiency everywhere; but I am praying that the day may soon come when "peace on earth and good will to men" will do away with the need of engines of war. I know there are many great and good men who claim these immense battle-ships are really *messengers* of peace; and it may be that Mexico is behaving a little better because of her knowledge of these things, especially when she considers the matter of permitting her subjects to lay hands on citizens of the United States.

High-pressure Gardening

"HIGH-PRESSURE" CANTALOUPE MELONS, ETC.

On former pages I have told you about pushing the dasheen with old well-rotted stable manure and irrigation. I think I mentioned, also, giving my cantaloupe melons some of the old well-rotted manure. Let me go a little more into detail. Some time in April I got a five-cent package of cantaloupe melon seed. I think they were Burpee's seed. I asked for the Rocky Ford strain of cantaloupe; but the dealer here in Medina was sold out, and gave me something that came from Burpee's that he thought "just as good." I have told you what bad weather for general garden stuff we had in April and May. Only a few of my melon seeds came up, and what did come up were such miserable-looking spindling things that I had very little hope they would ever amount to any thing. I covered them up with newspapers, however, during frosty nights, and about the time I got that rich old manure for the dasheens I gave some also to my melons. Now, this is the way I did it: I dug the soil away from each melon-plant. I pulled it back in a circle clear around the hill, and went down deep enough to uncover the white tiny rootlets. Then I filled in this cavity with perhaps a quart or two of this old heavy rich stable manure, mixing it in with the dirt. I finally soaked the manure and soil with water; then with my hoe I pulled some soft fine soil all up around the plants, covering the wet part so the sun could not make the clay soil bake. Some fine weather coming on soon, the melon-plants just woke up and astonished me. I visited them every night and morning, to notice the change—kept the dirt stirred around them, all the weeds out, and in a little while they were sending out runners. Under the stimulus of this rich manure they made an astonishing growth, and pretty soon melons were set in great profusion. I think I watered them only once after putting the manure around the roots. During the last of August we began to get ripe melons; and not only in our own home but from all around Rootville came expressions of "happy surprise." The melons in the market which had been shipped in from away off somewhere could not be compared with them. And right in here comes another of my "wonderful discoveries" in regard to God's gifts. The melons were so luscious, and there were so many of them, I began to use them for my evening meal instead of apples. This is the way I did it: Let the melon get good and ripe, so you can eat it with a spoon. Cut

it in halves, and scoop out the seeds; then have your five-o'clock supper of cantaloupe melon and nothing else. If the melon is real ripe you can scoop it out with a spoon until nothing is left but a thin rind. According to my notion you would need a little bit of cheese to go with your melon to make a "balanced ration."

Now, when you get hold of some melons fresh from the garden, as good as ours, if you do not agree with me that it is the most delicious meal you ever ate I shall be surprised; and the best part of it all is, that it causes no disturbance whatever to the digestive apparatus; whereas if I should eat a regular square meal as people generally do for the last meal of the day, I should be distressed all night, and have nightmare, etc. Just one word more:

If you have only a little backyard garden, by following the above program you can have beautiful nice melons that, on a rough estimate, would not cost you over a cent apiece; and in quality as well as cost they are away ahead of any thing you can find in the market—at least that, has been my experience. Still another word:

Some Hubbard squashes, about a dozen hills, near the cantaloupes, that had the same treatment, have run all over the garden, and there are fifteen or twenty most beautiful squashes, some of them about the largest I ever saw; and a wheelbarrowload of that old rich black manure did it all. If you want to reduce the "high cost of living," have a garden, even if it is only a little bit of one, and manage it according to the directions above given.

"PRACTICAL POTATO CULTURE;" ALSO SOMETHING ABOUT HEADING OFF THE BUGS.

I hold in my hand an excellent little book of 126 pages, by E. A. Rogers, of Brunswick, Maine. The book is chock full of excellent suggestions in regard to growing potatoes, not only in Maine but almost anywhere else. It also contains some beautiful pictures—a good lot of them—and it is well worth the price of any potato-grower or to anybody who is interested in the matter of better potatoes and more of them. Now, with all the good things in this book there is something else about it that troubles me a little. The following letter to our Experiment Station explains itself:

Ohio Experiment Station, Wooster, Ohio.
DIRECTOR THORN.

What troubles me just now is that in a book entitled "Practical Potato Culture," in speaking of the use of Paris green, arsenite of lead, and other arsenical poisons, the statement is made very vehe-

mently that the steady use of these poisons for a period of years gets so much poison in the soil that it damages vegetation, kills apple-trees, etc. They give two or three pages toward proving this statement. Now, T. B. Terry, you may be aware, says in his potato-book it's very much better to get along without poisons, and I agree with him. Perhaps if I were growing potatoes on a larger scale, however, I would use poison. Now, why I come to you in regard to this matter is that the book winds up its argument by recommending "Bug Death," and I am inclined to think the book is sent out by those concerned in the sale of "Bug Death." Could you briefly tell me what you think about the statement that "the continued use of Paris green or even arsenite of soda will injure the soil"? I feel satisfied Paris green usually injures the foliage of the potatoes more or less. That's one reason why I prefer to get along without it.

A. I. Root.

Below is a reply from Professor Gossard, the Station Entomologist:

Mr. A. I. Root:—Director Thorne has referred to me your letter of July 10, requesting that I answer regarding continuous use of arsenicals. The original investigations upon which these statements regarding the accumulative effects of arsenic are based were conducted by Prof. Headen, of the Colorado Agricultural College, on apple-trees growing in an alkali soil. It is probably true that the continued use of arsenicals on such a soil will finally work injury to the trees by putting arsenic into solution in water. The hair roots are said to be killed, and more or less of arsenic was found in the wood, bark, fruit, and leaves of these trees. Some other Western investigators, notably Director E. D. Ball, of the Utah Experiment Station, take issue with Prof. Headen regarding his general conclusion, and believe that caution is to be exercised only with trees standing in alkali land. However this may be, we know of orchards in Ohio that have been continuously sprayed with arsenicals and copper salts for 20 to 25 years, and the orchards are in the pink of condition, while surrounding orchards that were not sprayed at all are in far worse shape, most of them dead long ago. I have had occasion to sample soils in Ohio orchards where spraying had been done very liberally for a number of seasons, and we were never able to get more than a trace of arsenic in the soil or in the wood of these trees. The arsenic goes into solution slowly, and is carried away with the percolating waters. While I am in no position to say that enough arsenic might not accumulate in the course of a century to injure orchard trees, or other vegetation growing upon such soil, I think it rather improbable, and am sure that such sprays can be applied very liberally for more than a quarter of a century without perceptibly injuring apple-orchards planted on it, and in which grass, weeds, and the general mulch of the orchard appear to be in perfect health. I do not remember the exact composition of "Bug Death," but from a hazy remembrance believe that the poison principle in it is zinc oxide. It appears to me that an accumulation of insoluble zinc compounds in the soil would be as apt, and probably more apt, to cause injury to vegetation than arsenic would be.

Arsenic, in a small quantity, is a tonic to many kinds of plants, just as it is to the human being; and with the abundant rainfall we have in Ohio, and with the absence of alkali. I believe it very improbable that any damage whatever will be done to the soil in the course of half a century or more of continuous use. However, with such crops as potatoes and garden stuff, I would think it the part of wisdom to rotate crops, and not apply the spray oftener than once every two or three years. With this sort of usage it is improbable that Ohio soils

would ever be injured by the small quantities of arsenic used on potatoes.

I question if any one is able to give a much more definite answer than this to your question; but you may be able to get fuller experimental data from the United States Department of Agriculture.

H. A. GOSSARD, Entomologist.

Wooster, Ohio, July 12.

I am very glad to know that the danger alluded to is little or nothing in the average locality; but I wish to add one suggestion in regard to poison of any kind. Terry says in our potato-book that many times killing the first Colorado beetle as soon as one can be found, and followed it up, will often obviate the need of the troublesome business of spraying. When a potato first begins to shoot up out of the ground, give the little boys and girls a nickel for every bug they find. Later, when the bugs get to be more plentiful, give the children a cent apiece for them; then 25 cts. a hundred, and finally 5 cts. a hundred. A wise father can regulate the price so that the children will not make money *too* fast. I have done this repeatedly with my own garden, and I not only have *better* potatoes, but gathering the bugs and picking off the eggs is *less work* than using poison. Where your neighbors are close by, and allow the bugs to eat up their potatoes, I know it makes a little more work. At the same time you go after the bugs you can look carefully, not only after eggs, but for any weed that has got a start in the potato-hill. During this last summer I have greatly enjoyed this method of proving that "prevention is better than cure."

THE DASHEEN—MORE ABOUT IT.

We clip the following from the Jacksonville *Times-Union*:

THE BROOKSVILLE PLANT-TESTING STATION; "FOREIGN-PLANT INTRODUCTORY STATION" OF THE GOVERNMENT.

"The Stroller," in the last issue of the *Florida Grower*, has the following mention of this interesting and important institution:

"Brooksville has the distinction of being one of two places selected by the United States Government as a plant-testing station, the other being at Miami. Here the Agricultural Department has 35 acres of land, and has established what is known as a "foreign-plant introductory station." Here have been introduced many kinds of forage plants, foreign bamboos, foreign oranges and grapefruit, and last, but by no means least, 182 varieties of the dasheen. Of this number over one-half have been found to be practically worthless, and but three edible. The roots of these three varieties are used as substitutes for potatoes, some claiming them to be superior, and certainly they are very fine eating, being widely used for that purpose in the countries from which they came. One other variety is being produced in quantity for a tryout as to its value as a flour. Last year this station raised 45,000 pounds of dasheens. Of these, 15,000 pounds were distributed to growers and 30,000 pounds sent to Battle Creek to be tried out for flour.

Prof. Gomm, who is in charge of the station, says that the demand last year for seed was tremendous.

He sent the seed in four-pound lots; and to get rid of 15,000 pounds he certainly must have done a rushing business; and he further says he supposed that there were at least 1000 requests that could not be complied with last season. This season's crop will be distributed in the same way, as the Government wishes to encourage the growth of this food, which seems destined to help in a measure to solve the problem of the high cost of living. There are about five acres in the three edible varieties, and this field is certainly a beautiful sight.

I saw here South African millet standing eighteen feet high. Egyptian wheat is growing well, and there are thirty-five varieties of sorghum under inspection. The bamboo being tried are the Japanese varieties used in that country for building houses. Prof. Gomm is authority for the statement that several hundred thousands of dollars' worth of this bamboo is annually imported into this country for various purposes, so that this would seem to be the beginning of an industry in itself. For a soiling crop they are trying out an imported bean, which Prof. Gomm mentioned as the "Jack" bean. It grows to be seven or eight inches long; and, while I was told it was not edible, it looks like a mighty fine food for cattle."

Let me add that, since our report of the dasheen flour, some of our women folks are learning better how to use it; and this morning I ate a dasheen gem that was certainly equal to any thing I ever tasted in the bread line. So far as I know, dasheen flour can be shipped and kept like ordinary wheat flour. Inquiries are coming to me constantly, asking where they can get the dasheens. The above clipping tells us the Government is going to have additional lots in 4-lb. packages, and it may be well for the friends to get their applications in early. Don't write me, but apply to the Department of Agriculture, Washington.

By the way, what do you think of millet standing 18 feet high? Can anybody tell us more about it, or is it a misprint?

DASHEENS—STILL MORE IN REGARD TO THEM.

For fear my Florida quarter-acre might not be able to furnish a tuber or two to every reader of GLEANINGS, I directed a letter to the Brooksville Board of Trade, asking them if they would be able to help me out if I did not grow tubers enough to go around to our 30,000 subscribers. Of course, I do not suppose that every one of the 30,000 will apply for a tuber; but I want to be sure not to disappoint any one. Below is their reply:

Mr. A. I. Root:—Your letter of Sept. 20 is at hand, and is greatly appreciated. We are glad to be assured that you are taking such an active interest in the dasheen, and we hope that the seed stock you obtained from us last spring will bear abundant returns.

We have five acres out this year, and there are, perhaps, that many acres more in the hands of the farmers hereabout, so you see the crop this year will be limited. The Government has six or seven acres out at the Foreign Plant Introduction Station here, but we presume they will use them for distribution in 4-lb. packages as they did last year. You can rest assured, however, that we will supply you with a

portion of our crop, which will not be on the market much before the latter part of November.

If you wish to be on the safe side, be careful of what you do in the matter of distributing dasheens secured from South Africa, South America, New Zealand, etc. Your Uncle Sam at the local station is proceeding with the greatest caution in this matter, as you will readily understand when we tell you that, out of about 200 varieties obtained from foreign countries, they have as yet recommended but four as being superior for human consumption. Many varieties are yet too acid to constitute eatable stuff; and if they ever amount to any thing your Uncle Samuel will surely discover it here through extensive experiment. Therefore, test out every variety, or send samples to the Department to be tested, before you offer them to your patrons, or they may charge you with handing them something worse than a lemon—an Indian turnip. The dasheens that have been approved by the Government experts here are O. K., and we have reason to believe in a great future for them, as indicated by the reports of those who tried them in various parts of the country last fall and winter. They have been used by some of the most noted dieticians in the country, and have been pronounced especially good for persons suffering from any form of stomach trouble.

Then think of their versatility! You can treat the young stalks as celery, and secure a product superior to asparagus tips or mushrooms. A single planting will grow eight crops, coming off about every two weeks. You can also use the stalks for rhubarb and the leaves of certain varieties for greens. When the tuber matures you can use it in any form the potato can be used, or grind into flour and make of it any thing that can be made of wheat or other flour. You can make a pie-crust of the flour, and the filling of the stalk, as in rhubarb, or the tuber, as with the sweet potato or pumpkin.

My friend, if you would be initiated into the mysteries of propagating and harvesting dasheens, make it a point to visit Brooksville on your way South next month, and we will show you "sumpin'."

C. H. FREAS, Sec. Brooksville Board of Trade.
Brooksville, Fla., Sept. 23.

Later.—On receipt of above I asked if they could fill orders to our readers by parcel post, and below is their reply:

Mr. A. I. Root:—In reply to your letter of Sept. 26, I will say that we will be pleased to ship by parcel post any orders you may desire for your patrons, and sell you in quantity for other means of distribution.

If you can manage to get here in November, you will likely see the dasheen growing in all its pristine glory, for the stalks remain green until the frosts come. Try to be here.

The publication and clippings arrived all right, and we were glad to note the mention you make of the stuff that made Brooksville famous. The writer has written enough about that tuber to fill two volumes, and I could write as much more if it were necessary. We will be glad to have you visit Brooksville at your earliest convenience.

Brooksville, Fla., Sept. 29. C. H. FREAS,

Please notice what they say of it in regard to acidity. Mrs. Root has just been urging that I should give also the objectionable features of the dasheen as well as the good. Well, cooking entirely destroys this acidity. Here is what the Government bulletin has to say in regard to this matter:

The leaves of the dasheen contain the same acid principle that characterizes the Indian turnip and most other plants of this family. They should never be tasted raw. The tubers of the most promising

Trinidad varieties are free from this acidity, even in the raw state; but because of the possibility of tubers of an acid variety being mixed with these it is best never to taste them uncooked. In cases of the accidental tasting of acid tubers or leaves, lemon juice in a little water is found to alleviate the ill effects.

If dasheens are handled in water in scraping or paring them for cooking, a level teaspoonful of sal soda should be added to each quart of water. The outer part of the tubers contains an irritant that causes the hands to sting in somewhat the same way as the mouth and throat from the eating of raw, acid leaves or tubers. The hands are affected in this way even in the case of tubers that are not acid to the taste. If water is not used while scraping them, it is best to wash the hands afterward in soda water of the strength mentioned.

The fat of milk or meat seems to assist in destroying the acidity.

Hunters are well aware of a similar property belonging to the Indian turnip, alluded to in the above letter. Please notice their endorsement of what I have told you, that the dasheen, every particle of it, at every stage of its growth, is valuable for human food; and not only that, it is a delicious article of diet.

One word more about the tubers to be given our subscribers. They are to be sent only to those who apply, and who have their subscription paid up for one year or more from the time of applying. Send in your applications when you choose. We expect to mail them from our Florida home somewhere about the first of January. As they are injured by freezing, perhaps the friends in the extreme North had better not order them sent until it is time to plant, say March or April.

THE AMADUMBE DASHEEN OF SOUTH AFRICA; SEE PAGE 698.

Mr. Root:—Your recent letter was received on the 13th, and the package the 14th. On the 15th I planted them. I took the responsibility of planting on Mr. Ault's land, as his dasheen show so much better than mine or yours. It is very evident that the dasheen needs much moisture as well as an abundance of fertilizer, both organic and chemical, for best results. We had some for dinner yesterday (small ones) that I fingered out from your first planting in January. I am afraid you are going to be disappointed in the yield. Your land is entirely too dry. Ault's land had water standing in the ditches each side of the rows all summer.

As to the edible qualities, we think we would rather have a good Irish potato.

MR. AND MRS. C. L. HARRISON.

Bradentown, Fla., Sept. 16.

The above corroborates what we have said before, that the dasheen, in order to grow to perfection, should have wet ground, or ground where the roots can get down into running or standing water; and the fact that ours down in Florida did not have this wet ground is, may be, why friend Harrison thinks he prefers a good Irish potato. We have now cooked quite a few here in Medina; but so far they are hardly

mature enough to make a nice baked dash-
een; but the outside tubers cut up and made into a stew like mushrooms is certainly a splendid substitute for a mushroom. And please consider that mushrooms sell for from 40 cts. to \$1.00 per lb., while the dasheen may be grown for 40 cts. a peek without any trouble. When Mrs. Root suggested that I might be giving it too much praise, Huber replied, after I carried over to him a little dish for breakfast, "Father, you *can't* give it too much praise." The other children, however, were not quite so extravagant. Now excuse me for the following summing-up as I see it: The dasheen can be grown *anywhere*, and every bit of the plant is *edible*—the tubers under ground, the tender shoots above ground, for a stew, and the great green leaves (if they are not too old) for greens. It may not fully mature here in the North. That is not quite settled; but it will certainly grow these luscious small tubers with their tender shoots as a substitute for asparagus.

THE HYBRID TOMATO SEED, ETC.

Mr. Root:—I should like to make a few additions to your article on tomato hybrids in the Sept. 1st GLEANINGS. First, the New York Experiment Station is at Geneva, not Oneida.

In cross-fertilizing the tomato, not only does the pollen have to be carried from one blossom to the other as you have described, but the anthers of the blossom have to be removed before they commence to shed their pollen, as the tomato blossom is a self-fertilizing flower, and cross-fertilizing does not take place readily.

Now as to the varieties. I used the Earliana in quite a number of crosses, and it was quite good; but it made a too soft tomato. But the best results I obtained were by a dwarf tomato. This seems to give a stronger and more vigorous plant, as was found by the New York Experiment Station. The dwarf that I used was one that I originated, and not only makes a vigorous tomato, but one that has a solidity found only in the late kinds. In canning I find my hybrids of this cross were far superior to the Earliana crosses. It is only in canning or shipping that this quality becomes noticeable. Down in Marietta, O., where over 500 acres are grown on stakes, early, and shipped to such places as Cleveland and Chicago, they never use Earliana, but mostly Beauty.

This matter of first-generation plants is an interesting one. Corn is another crop that seems greatly benefited by crossing. Prof. East, in an article in the *Country Gentleman*, last October, made the statement that from 20 to 150 per cent of gain had been made in many cases. It seems strange that some enterprising seedsmen does not produce such seed for sale; but Henry Field, of Iowa, is the only one whom I know of who has offered it yet.

It may seem a high price to pay \$5.00 per ounce for tomato seed; but when we know that an ounce of seed will make enough plants for two to four acres, the increase of yield will pay many times over for the cost of the seed.

I wish somebody would offer crossbred corn for sale. I am going to do what I can in tomatoes, and it looks as if the readers of GLEANINGS would use up my supply of seed, as they seem to be an unusually up-to-date lot of people.

Medina, O., Sept. 18.

E. C. GREEN.

Poultry Department

CONVERGENT POULTRY-RUNS ACROSS THE WATER.

Dear Sir:—Since the time you published my article about the convergent poultry-runs, Nov. 15, 1912, I have not seen any thing further on the matter; so I thought you would like to hear the opinion held over on this side.

The chief drawback seems to be in the great length of the run when compared with the width, as the fowls are not inclined to keep the grass down at any distance from the house; and to overcome this Mr. Wright gives a plan of a plant of eight houses, sheds, and runs, which I enclose.

Our runs are occupied all the year round, so we have to allow more grass than you do.

Area of plant, $\frac{1}{2}$ acre, consisting of eight houses, sheds, and runs. A, roosting-house 6 ft. square. B, scratching-sheds 12 ft. square. C, grass runs.

From Lewis Wright's Illustrated Poultry Book.

Personally I prefer the colony system, which Mr. Wright credits to Mr. Stoddard.

LINE GOOD FOR CLOVER.

I am afraid you missed the point in the leaflet taken from the Mark Lane Express about lime. Although it was printed in 1910 it was an article on farming in the 16th century in England, and went to show that the old timers knew that lime was good for clovers. Lime and salt are the two oldest artificial manures in existence, and are largely used in this country as well as seaweed.

FINDS BLACK BEES SUPERIOR TO ITALIANS.

I was pleased to see in the Jan. 15th issue J. E. Crane's remarks about the good old blacks. All the other "Gleaners" seem to think them of little value; but I can assure you that I have had Italians direct from Italy, and that they can't gather honey as do the blacks, and they are not half as good at wintering.

W. A. TEARE.

Ballashellan, Ballabeg, Isle of Man, Jan. 2.

Many thanks, friend T., for the pains you have taken to keep me posted. The diagram you give is certainly very ingenious, and might answer an excellent purpose for a half-acre poultry-farm. There would certainly be economy in constructing such houses, especially for a cold climate. I would, however, greatly prefer having an open court, and houses around the outside. This isolates the eight different roosting-

places. The arrangement you give, you will notice, will be a rather bad place if vermin or some contagious disease should get among the poultry. I have used the plan I have described, one winter. The inner court I have spoken of is 45 feet across, with the granary in the center. No chickens are allowed in this inner court or inclosure, and it can be kept as neat and tidy as you please; and at the same time the eggs may be gathered, fowls supplied with all they need right in this one spot, and yet the chickens can go away off in every direction just as they do on the ordinary farm. Ours frequently go away clear out of sight, both young and old. On account of the trouble with the hawks, however, we keep the small chicks in a covered inclosure until they are able to take care of themselves.

In regard to black bees being superior to the Italians, this sometimes happens in certain localities or with an extra good strain of black bees. I believe, however, our great honey-producers the world over prefer the Italians as a rule; but it has been intimated that a cross between the two races, even if they are ugly, will get a larger crop of honey, many times, than either the pure blacks or pure Italians.

DUCKS AND CHICKENS SWALLOWING CROOKED RUSTY NAILS, ETC.

The letter below accompanies a photograph of the contents of a duck's crop.

EXTRAORDINARY DEPRAVITY OF APPETITE. . .

This collection of "ironmongery" was removed from a duck owned by Mrs. Bloomfield, of Taringa, Brisbane. The bird died after a few days' illness, and an autopsy revealed the cause of death—sixty-two nails, bent and straight, varying from one inch to two inches; three iron boot-tips, one one-inch screw, and four wood tin-tacks, all of which had been swallowed by the duck, and were in an advanced state of rustiness.

Under the photo we read the following:

I see you take a keen interest in poultry and ducks; but I think the photo of the diet that the duck in Brisbane, Queensland, took, can "go one better" than all your American ducks, allowing that all exciting things generally come from America.

WALTER LINCOLN.

Toowoomba, Queensland, Australia, June 2.

The picture reveals that the nails were mostly crooked ones. This particular duck, no doubt, was foolish enough to think that they were worms. I remember, also, that Kellerstrass in the first edition of his book advised against allowing rusty nails, especially crooked ones, to lie around where the chickens might get hold of them. Since that time I have kept watch to see if any of our chickens could be fooled by crooked nails or pieces of rusty wire. I have never found one that was foolish enough to swal-

low such an object, and therefore I can not think that it is a very common thing for a chicken to hurt itself by swallowing such objects, although it might happen at times.

HOT TALLOW FOR THE RED MITES, ETC.

Dear Mr. Root:—I have followed your poultry articles with interest, being particularly interested in the article about "convergent" yards. Some time ago one of your correspondents wrote that he prevented mites by coating his roost-poles with hot tallow once a year only. I had lately bought a farm that had a chicken-house very much infested with red mites. I had been painting my roosts once a week with crude petroleum scented with sassafras and cedar oils. I substituted the hot tallow, but one week later found the mites in quite increased numbers. I resumed the petroleum, and now have them almost exterminated. An application of tallow followed by petroleum once a week is a very good thing indeed, as it makes the poles more slippery than the petroleum alone; but I don't think the tallow alone will do the business.

CHARLES A. JOHNSON.

Battle Creek, Mich., July 25.

WHY HENS PULL AND EAT EACH OTHER'S FEATHERS.

As I am making the Rhode Island Reds a specialty I write you in regard to feather pulling and eating. I am a subscriber to GLEANINGS, and enjoy it very much, and suspect you know something about hens as well as bees.

Cuba, N. Y., Aug. 25.

Mrs. C. E. PETTIT.

My good friend, there are two or more reasons why hens should pull feathers from their mates, and eat them. One is that they are lacking animal food. Give them beef scrap or ground meat. The other is they are probably shut up in too narrow quarters, and lack green stuff. Give them all the lettuce and cabbage, etc., they want, and also give them a mash containing salt, but not too much. Salt about as much as we do our food, then let them run outdoors in a large yard where they can get bugs as well as green stuff, and I think they will get over it.

A 25-YEAR-OLD HEN; A SUGGESTION IN REGARD TO A "NATURE" BROODER.

I give place to the following, clipped from the *Farm and Fireside*, because it tells us how old a hen may live to be, and suggests also a brooder for chickens on nature's plan.

A hen owned by the writer, and having quite a remarkable history, has recently joined the majority of her kind. I bought this hen in 1890 for half a dollar. She was just a plebian yellow hen, without family or reputed pedigree. "Is she young?" I asked of the seller. "She's not old; she's not laying," was the reply.

I scanned her feet, as a buyer does a horse's mouth, to guess her age. I concluded she had seen a couple of summers or more. I therefore believe her to be at the time of her death, in April, 1913, about twenty-five years of age. She made good her reputation as a "fair layer."

She began to fail in strength when about ten years old. But she kept on laying and rearing her broods.

That is, she laid irregularly, and in 1912 one egg only. Her eggs had ceased to be fertile for several years, or after she began to look old.

"Why was her life prolonged?" She would mother any brood from quail to turkeys, at any age offered, even after she was too crippled to scratch for them. In her later years a brood of young fowls was always given her in the autumn to insure her own safe passage through the winter. These chickens thought the mother hen hovered them, and were satisfied with the warmth always obtained by cuddling; but it was the vitality of the young which kept the old alive.

Of course, this does not prove that *any* old hen would receive any kind of chicks of any age, but it looks that way. Once in a while we find a hen that is that kind of mother; and we are told that capons will care for chicks all right. A hen that will take any brood of chickens from an incubator, or which are left motherless for any other reason, is very handy to have in the poultry-yard; and one such hen put in a barrel will take good care of as many as 70 day-old chicks, as I have told you. The ones outside will change places with those inside, and keep quite comfortable, even during frosty nights.

PERMANGANATE OF POTASH FOR POULTRY.

If I am correct our leading authorities agree that a little permanganate in the drinking-water—just enough to color it a little—is a benefit in warding off contagious diseases.

The following from one of our poultry journals (I regret that I can not say which one) suggests something else, and it also tells how to get it at a low cost.

I find in using permanganate of potassium in the drinking-water that it eats or keeps away the slimy substance that otherwise adheres to drinking-vessels, especially in warm weather. If you wish to get it cheap, go to the man who takes care of the fumigating in your borough, county, or township, and buy a pound from him (if he will sell it). Here I can get a pound for 22 cents, whereas to buy at a drug-store it costs 50 cents. It is burnt in the fumigating of houses for contagious disease; and if the Board of Health handles it, it comes cheap.

A "BOILED DOWN" POSTAL CARD.

You may recall that I have something to say about this in our issue for Oct. 1; and our good friend Madeleine E. Pruitt seems to have fallen in with my suggestion.

To Our Homes for July 15 I will say, "Amen." New baby here—girl. MADELEINE E. PRUITT. Abilene, Tex., Aug. 18.

It might be a little impertinent to ask the question; but there are quite a few of us who would like to know just who is the mother of that girl baby. May God bless her and the mother too.

Temperance

SHALL WE CONTINUE TO GET OUR "REVENUE" FROM THE BREWERS, SALOON-KEEPERS, AND DISTILLERS?

Mr. Root:—I always read your Home Department with interest. In the paper of Sept. 15 you publish a letter of G. M. Doolittle, in which he seems to give credit to the saloonkeepers for paying half the revenue, and says: "We are, willingly or ignorantly, receiving pay to the half of our proportion of the government expenses through the efforts of the saloonkeepers." Surely Mr. Doolittle is not seriously attempting to condone the sale of intoxicating liquor. As an intelligent man he must know that three-fourths or more of all the crime and poverty, and the resulting misery and degradation, are caused by drink.

As for myself, I am neither willingly nor ignorantly receiving my share of the taxes paid by the saloon-keeper. I accept it under bitter protest, being forced to do so by laws made by men who are blind to the awful results of the legalized liquor-traffic in our land, or are bought over by the liquor interests.

How can any part of the expense of the general government be said to be paid by the saloon-keeper when every dollar of liquor revenue costs the people more than ten? And this is only the monetary view of the matter. No amount of revenue paid to a government can make amends for the misery, poverty, and ruin brought upon its people through the legalized sale of injurious drugs or intoxicating poisons.

Your reply to Mr. Doolittle is all right so far as it goes; but does it cover the ground? If we could persuade all the young people to "seek the kingdom of God and his righteousness" there would still remain the blighting effects of the traffic in intoxicants with its consequent misery and poverty, forced upon the wives and children of the incorrigible fathers and husbands, made drunkards by our government's willingness to (in the language of the poet of the Sieras) "sell hell to whom will pay for it." God not only commanded the Israelites to bring up their children in his fear, but those who led the people astray were dealt with in a way to strike terror to evil-doers. Not only did his prophets teach the evils of idolatry, but those advocating idolatry, the false priests, were slain without mercy.

Let us not only teach the children of our generation the dangers of intoxicating liquor, but do all we can, also, to destroy from the earth this Juggernaut that is crushing the life, spiritual and physical, out of hundreds of thousands of our people.

If every one who claims to be seeking the kingdom of God and righteousness would vote for the destruction of the distillery and the brewery, the greatest hindrance to the coming of that kingdom, and Satan's most efficient instrument for the ruin of the human race, would be removed.

Asheville, N. C., Sept. 21. O. BROMFIELD.

Dear brother, Mr. Doolittle, myself, and all good people, are in hearty accord with what you say. May God hasten the day when his kingdom shall be first in our nation—not the brewers and distillers and liquor-dealers.

KANSAS—SOMETHING FURTHER "THE MATTER" WITH HER.

A few years ago there was some sense when the brewers said that prohibition was a failure; but it is a piece of stupid folly to keep up that old story just now. What brought it about? A few days ago I heard a remark from a man of considerable abil-

ity, that it was a question whether Carrie A. Nation did not do more harm than good. I have seen Carrie Nation and talked with her. Bless her memory! When the brewers and saloon-keepers were trampling law under foot in Kansas, our good friend Carrie took a hatchet and smashed things up. Then she said to the Governor of Kansas, to the mayors, and different officials, all the way down, "Put me in jail for breaking the laws if you choose. I have done some harm in the way of loss of property, etc. But before you enforce the law in my case, please consider the saloon-keepers who curse both body and soul by trampling law under foot." The grave judges and magistrates were in a corner. It behooved them to be consistent, at least where a woman was concerned; and the final outcome was that Kansas became a model State in the way of law enforcement. See page 699, Oct. 1.

Now, here is something further about that same Kansas that I clip from the *Union Signal*:

KANSAS YOUTH UPHOLD PROHIBITION LAW.

Again and again it has been said prohibition is a failure in Kansas; that when the older generation responsible for its adoption passed over the reins of government to its sons and daughters—for Kansas has recognized women's rights as full citizens—Kansas would "come back to her senses."

That this prophecy was without foundation is best evidenced by the following statement from Attorney General Dawson:

"The last two sessions of the legislature answered these false prophets by passing the most drastic prohibition law in the world, killing the drugstore saloon, making it impossible even to cure snake-bites by the liquor treatment, and absolutely clapping down the 'lid' and riveting it on.

"They were not satisfied by going this far, but showed their appreciation of the benefits of State-wide prohibition by making it a felony for the fellow who violated the law a second time. And I have just lately received from the warden at the penitentiary a receipt for one 'Red Mercer,' who was sent up from Barber County as a first consignment to serve nine years for violating the new prohibition law.

"The law that sent him there was made by these tow-headed, one-gallused boys who grew to manhood on the Kansas prairies without ever having seen a saloon."

WHISKY FOR PATIENTS IN A TUBERCULOSIS SANITARIUM.

It seems from the *Cleveland Plain Dealer* that the superintendent of the sanitarium has been criticised for refusing whisky to their patients. See this:

"Superintendent Wright has no conception of medical ethics, and endeavored to discipline physicians and nurses as though they were children. I believe a mistake was made in choosing Wright."

Dr. Fox was asked if he knew that patients in the tuberculosis sanitarium, many of them dangerously ill, had been deprived of whisky at critical times.

"Yes," he replied. "There is this about the whisky situation: Mr. Wright called in the medical staff,

and asked that the amount of whisky furnished patients be cut down. It may have been that whisky had been used a little too freely, but depriving the patients of the stimulant at needed times was far from wise."

I take it from the above that the trouble with the superintendent was that he is a little more up to the times in regard to the use of whisky as a medicine. Now, I should like to submit this whole matter to the intelligent, up-to-date physicians of our land. If I am up to date myself, the decision is that alcoholic stimulants are the very worst things in the world for a tuberculosis patient. If the patient must die any way, and you wish to hurry up his death, give him whisky. The fashion of giving a patient whisky to make him feel better as he approaches death, I know used to be very common; and many a poor soul has been hurried to a drunkard's grave simply through the mistaken kindness of nurses and physicians who ought to have known better. I for one prefer to die without the whisky, even if it does take a little longer. Mrs. Root's father, when near death, protested because the doctors said he *must* have whisky. He said, when almost too feeble to speak at all, "I do not want it, and I do not need it. You are making me a drunken man." And, thank God, we were able to overrule the doctors, and let the good old man die sober, years ago.

Later.—Oct. 6 we find in the *Cleveland Plain Dealer* more about the probe instituted because of the complaint of the inmates of the hospitals. Here is a report of what one matron said before the committee:

"Give them all the *whisky* they want, and it would be all right," Miss Kelly further told the committee.

Further on we read:

He said that in Dr. McAfee's time patients had whisky three times a day.

"Now we get it only once a day in the morning—and a mighty small glass at that," he added.

Just think of it, you friends of temperance and Christian people. In this sanitarium for tuberculosis patients, a comparatively able man confesses that he used to have "whisky three times a day." But under the present superintendent he gets it only once a day, and not a full glass of whisky even then. Is not this probe or investigation letting some pretty big cats "out of the bag"?

"MIGHT AS WELL TRY TO STOP THE WAVES OF THE OCEAN."

We clip the following from the *Union Signal*. See if you do not think it is about right.

In a frantic attempt to stem the tide of public sentiment which threatens to sweep them from the nation, the liquor interests are outlining plans for reform. "If the liquor-dealers do not want to see

this State dry in two years," the president of the Ohio Liquor League is reported to have said, "they must not only live up to every State and municipal legal requirement, but they must help to bring about certain reforms not on the statute-books." The warning is most timely, but we apprehend that none of the contemplated reforms will avert the threatened calamity. It is becoming more apparent every day that you might as well try to stop the waves of the ocean as to stop the tide of prohibition.

The liquor men have always had to admit that, when the Christian men and women of the nation whole-heartedly and aggressively determine to "make the map all white," it will be done.

IS EVIL IN THE ASCENDENCY?

Dear Bro. Root.—I have just read the letter in *GLEANINGS* by Bro. Doolittle. You will notice that the increase of revenue from liquors and tobacco in one year is about .05 2-3 per cent, while the increase of population in one year can not much exceed .02 per cent. In spite of all that is being done to check intemperance, it increases nearly three times as fast as the population. And the increase in crime marches hand in hand with the increase in intemperance. Facts are stubborn things. It is foolish to ignore them. Speaking in a broad way, the forces of our enemies are the victors; and unless there is a change we shall soon be like Sodom—ready for the fire to destroy. The present mighty effort of God's people to clean up this earth fails to do it. What we can not do, God will do. Jesus is coming. The last message to this truth (Rev. 10:11) is now world-wide, and my spirit says "Amen."

Riverside, Cal., Sept. 20.

W. E. LITTLE.

My good brother, what you say is, I suppose, to a great extent true; but, if I am correct, the figures you give come either from the brewers and liquor people, or from some government official who is not in sympathy with prohibition. If you will read the *American Issue*, published at Westerville, Ohio, you will, I think, get the *full* facts in the case. It is true that a large quantity of liquors has been recently manufactured; and the statistics tell what has been made, and the brewers would make us believe that it has *all* been consumed as a beverage, which is not true.

"SOCIETY MUST PAY THE PRICE."

Presuming our readers have all read about the trial of Diggs and Caminetti, I omit details, and simply give the summing-up of Judge Van Fleet after sentencing them not only to pay fines but to go to the penitentiary.

I wish to say that all through this case there is the evidence that drink had its paralyzing influence upon the morals and the minds of these men and the young girls with whom they went on that trip to Reno. The terrible, debasing influence of the saloon and the roadhouse is too disgustingly apparent, and I make the observation here that society must pay the price for permitting the existence of these highly objectionable places.

May God be praised for a judge who does not hesitate to come out so plainly and square-footed against the saloon; and may he grant that no petition to have them pardoned out just because they have money may be forthcoming.

WATER-BOTTLES AND HARD CANDY FOR MAILING QUEENS.

WE are now continuing our experiments in supplying queens by mail by the use of little tin water-bottles. So far the results have been highly satisfactory. We will make no positive predictions at this time; but we believe that the use of water in our mailing-cages will enable us to use a hard dry candy. It will be much more satisfactory than any of the soft candy, for that is liable to be too soft, and run out of the candy-holes and daub the bees.

MOVING BEES BY WAGON WITHOUT CLOSING THE ENTRANCES.

THE conservative Mr. Doolittle, in his regular department in this issue, recommends moving bees by wagon without closing the entrances of the hives, even when the motor is a horse, and he is right. When the entrances are left open there is no danger of suffocation; and even during hot weather bees will not cluster out much if the moving be done toward night or early morning. Of course, when the automobile truck is used there is no danger of bees getting out and causing trouble.

MADAM MAETERLINCK PREACHING THE USE OF HONEY IN COOKING; HONEY-CURED HAMS.

IN these columns we have already referred to Madam Maeterlinck, the wife of the great Belgian poet, Maurice Maeterlinck, is an enthusiast in regard to the use of honey in cooking. We have already given one or two of her recipes. A number of her fine recipes are being circulated through many newspapers of the country, together with a writeup on Madam Maeterlinck and her views in regard to honey as a food. These articles are ably written; and as the recipes are all good they can not fail to stimulate the use of honey to a great degree.

As is well known, in olden days honey was used as one of the materials employed in the curing of hams. One of Madam Maeterlinck's recipes mentions this. We give herewith the recipe in full:

To make it, a brine is formed of four pounds of coarse salt and an ounce of saltpeter; two pounds

of honey and two gallons of water. All the ingredients are well blended and poured over the hams, which are permitted to rest in the honied brine for six weeks, when they are found to be marvelously saturated with a flavor that is truly indescribable.

OUR COVER PICTURE.

THE view on the cover for this issue is from a negative originally made by W. Z. Hutchinson. It shows a method of protecting hives by means of a super filled with packing material, and building paper wrapper around the brood-chamber. This is a plan that gives satisfactory results in a locality where the winters are not severe, where the temperature seldom goes down as low as zero, and then for only a few hours.

Better results are secured if another piece of paper is properly wrapped and folded over the cover lapping down over this under piece so as to shed the water. Otherwise the rain will run down the side of the super and thoroughly soak up the hive-body, and keep it wet. Tacking strips of lath along the upper edge of the paper helps to shed the water, and does very well for spring protection; but another piece of paper over the cover lapping down over the brood-chamber is better still. A very wide piece of paper will answer for both if, after being folded down over the cover, it will extend to the bottom-board. Where it is impossible to obtain paper wide enough we advise the use of two pieces, as above mentioned.

THE AUTOMOBILE TRUCK FOR OUT-APIARY WORK.

ON page 775 of this issue will be found a reply to R. V. Cox as to the value of an automobile truck for out-apiary work. We may say in this connection that the machine has not only proved its value in beeyard work, but it has been used to good advantage in delivering honey to the city markets. We have used it in carrying exhibits from fair to fair; in making quick trips over long distances. One day we drove it over one hundred miles.

The great advantage of the automobile truck for the beekeeper of 500 or more colonies is that it will deliver his honey clear up to the door of the consumer or to

the store of the retailer. When honey is shipped by freight to the city markets it then has to be carried by a careless and indifferent truckman to the consignee. We find in some cases that we are able to deliver honey cheaper by automobile than we can by freight. Another thing we are beginning to see is automobile trucks from the city, loaded with freight for our suburban towns—especially those towns that are not reached by railroads. The only thing that seems to be a necessity are hard stone roads. A community that has not gumption enough to have roads that are good the year around ought to be left out in the cold.

WHY IS SWEET CLOVER HAVING SUCH A BOOM IN OKLAHOMA AND KANSAS?

A. I. ROOT has been inquiring why there seemed to be such a big demand from Oklahoma for our sweet-clover pamphlet. As we made a trip through both Oklahoma and Kansas last winter, perhaps we can answer the question. Kansas especially has been a great corn State. The farmers there seemed to have the impression that they could grow nothing but corn and buffalo grass. In later years they have discovered that alfalfa grows well on low lands next to the little creeks and rivers; but it will not grow on the uplands. They are just beginning to discover in some sections of Oklahoma and Kansas that sweet clover will grow on these same uplands where formerly buffalo grass would be the only thing that seemed to thrive. The result is that the farmers in those States are finding out that sweet clover is going to enable them to make use of their poor lands that heretofore have yielded but scant returns. After these uplands have been inoculated with the bacteria, sweet clover will thrive and yield luxuriantly. Well, these same farmers are turning their stock—sheep and pigs—on these sweet-clover uplands, with the result that stock-raising is beginning to develop to a proportion that is going to mean the emancipation of much of these bad lands that hitherto have been almost useless.

SWARMING NOT CONTROLLED BY RAISING THE HIVE UP ON FOUR BLOCKS; CARNIOLANS INVETERATE SWARMERS.

Two or three of our correspondents, particularly Mr. Foster in this issue, do not believe it is advisable to place too much dependence on raising a colony up on four blocks to check or control swarming, as shown on pp. 593 and 610, Sept. 1st issue. Probably much will depend on the strain of bees and the supplementary management. We regard Mr. Vernon Burt as one of the

best beekeepers in the country. Any one who will talk with him for a while will be convinced that he is not only on the job, but knows it from start to finish. He has been using this scheme for swarm prevention for the last two years—years when we have had at our own yards some unpleasant experiences in shinning up trees after swarms. We tried the four-block method at our Carniolan apiary, but it apparently had no effect. As a matter of fact, every thing we tried failed; and we came to the conclusion that, when conditions generally are favorable for swarming, the Carniolans will swarm in spite of us. In this locality we do not regard them as satisfactory for the production of comb honey as the ordinary leather-colored Italians. They will breed up earlier, and work earlier and later in the day; but, my, oh my! this very breeding aggravates the swarming problem later on; and when Carniolans start to swarm you may reasonably expect they will not do much else in the way of honey production that season.

THE ADVANCE IN THE PRICE OF HIVE LUMBER; HOW LABOR HAS ADVANCED; COST OF HIVES NEW AND OLD.

IN this issue, page 750, Mr. P. C. Chadwick calls attention to the steady advance that has taken place in the price of hive lumber during the past 20 years. What is true in California is more than true in other parts of the United States. A few days ago a subscriber, noticing that the price of bee-supplies was going to advance this year, complained, saying he thought it was unjust and unnecessary. This complainant probably failed to take into account the advance of the cost of living, the cost of labor, and the cost of general commodities during the past six or seven years. Nearly every thing has gone up—so much so that it is a real problem how to make ends meet. The wife of a workingman is obliged to figure much more closely than she did ten years ago, because the wages of her husband, although they may have advanced, are not yet quite up to the relative advance in the cost of living.

If it costs more to build a house now than it did ten years ago, it is reasonable to suppose that it would cost more to build a hive, because to a great extent the same class of labor and material is employed in each. As Mr. Chadwick points out in the article referred to on page 750, the price of second-hand hives to-day ought to be worth nearly the price of new ones. While hives ten or twenty years ago cost less, the natural depreciation during that period nearly balances the appreciation in the value of mate-

rial and labor entering into the newly made goods; or, to put it another way: A house built fifteen or twenty years ago for \$1500 is still worth nearly that amount in spite of the wear and tear and depreciation, because a new house like it can not be built to-day for less than \$2500.

As Grover Cleveland once said, "We are confronted by a condition and not a theory." We may complain about the advance in the price of the cost of living, but the fact remains that the cost of nearly every thing has gone up, and why not bee-hives?

After writing the foregoing, we ran across an item in the Oct. 23d issue of the *Cleveland Plain Dealer* that is very much to the point. Here it is:

TELL HOW COST OF BUILDINGS GROWS; EXPERTS GIVE FIGURES ON CONSTRUCTION AT REALTY BOARD LUNCHEON.

Cost of dwelling construction has increased 15 per cent in the past four years. Cost of building factories and other large structures has risen 17 per cent in the same time. These statements were made to the Real Estate Board at its weekly luncheon yesterday. Arthur P. Cody, real-estate man, explained the increase in the cost of building houses, while Lawrence Slatmyer, associated with his father, Henry Slatmyer, in the contracting business, told of the cost of erecting large structures.

"Carpenters twenty years ago were getting 17½ cents an hour," said Cody. "To-day they are getting 50 cents an hour."

The difference between the increased cost for dwellings and that for larger buildings was attributed by Slatmyer to the fact that a large amount of unskilled labor is employed in excavating for and erection of the latter, and that this labor has had an advance of 20 per cent in wages during the past four years. He pointed out that the average increase for all kinds of construction has been about 5 per cent a year. He declared that a factory building erected four years ago which cost \$62,681 to-day would cost \$73,779.

THE MILLER SMOKE METHOD OF QUICK INTRODUCTION.

WITHIN the last few days we have introduced sixty or more queens into as many colonies by the Miller smoke method. The weather during this time has been hot, cold, chilly, wet, and bright. Three or four colonies, on account of our difficulty in being able to get queens in time, were queenless so long that they had developed laying workers. However, we used the method described by A. C. Miller on page 370 of the current volume, and every queen was successfully introduced, *including the three colonies of laying workers*. It is well known that the ordinary method of introducing fails with laying workers; but the smoke method seems to be a sure thing in season and out of season with all kinds of colonies, whether queenless or not.

Here is the experience of another that is worth recording at this point:

I had a colony of bees that bothered me all summer. Early in June they lost their old queen and

failed in getting another. A cell hatched, but evidently the queen was lost in her virgin flight. I did not discover that they were queenless for more than two weeks; and as soon as I did I tried to introduce a queen by the cage-and-candy method. I tried this and failed. Then I tried to give them mature cells, but they would not accept them. I next gave them two frames of brood; but by this time there were laying workers in the hive, and they would not build cells. About the middle of August I wanted one of my mating boxes that already had a laying queen in it that was clipped. I did not care about this queen, so I thought I would try to introduce her into the hive that I have mentioned, by the smoke method recommended by Mr. Arthur C. Miller, p. 370, June 1. The next day I looked into the hive and found my clipped queen. She had been accepted, and had nearly filled one comb with eggs. At this date, Sept. 10, she has the hive well filled with brood.

A. S. KINNEY.

South Hadley, Mass., Sept. 10.

"Why, the other day," said our apiarist, Mr. Marchant, "by error I introduced by the smoke method a queen in a hive where there was already a nice laying queen. Would you believe it? they accepted the introduced queen and killed their nice layer! What do you think about that?"

If this method shall continue to be as successful as it has been with us during the last six months we shall recommend it exclusively, and, what is more, it will be possible for queen-breeders to sell virgin queens. Heretofore the business of selling such queens has been unsatisfactory, in that the recipients were not able to introduce them by the ordinary caging plan. But the Miller method makes a sure thing of it. A virgin can be had for about half the price of a laying queen. It will thus be possible for thousands of beekeepers to avail themselves of choice stock from our best queen-breeders at a very low price, and then have that stock crossed with their own vigorous strain. Truly this will be a great step forward.

THE SMOKE METHOD OF INTRODUCING IN ROBBED-OUT COLONIES.

After dictating the foregoing the following letter came to hand. As it describes a condition where the smoke plan of introducing was put to a severe test, we give it right here:

When I saw the article in *GLEANNINGS* by Arthur C. Miller in reference to direct introduction by the smoke plan, page 370, I was very much pleased, and at the same time had my doubts whether it would be a success. Nevertheless I made up my mind to try it. Having found one of my colonies hopelessly queenless, and having tried every thing I could think of to get a queen in without any success I ran a laying queen in on the Miller smoke plan. After I had opened the entrance about an inch the rest of the bees began to rob this hive, so I closed the entrance up tight and left it closed until very near dark, and then opened it about an inch. The next morning the robbers were as bad as ever, so I made up my mind to let them finish it up, which they did; but, remarkable to relate, the bees that belonged to the hive stayed there, and the next day were carrying pollen. I looked in the hive and found them all right, with the queen that I ran in laying finely.

This I consider a success under the most difficult circumstances.

Muncy, Pa., Aug. 23.

W. P. MERRILL.

A GREAT SCHEME FOR WINTERING; MOVING CARLOADS OF BEES FROM THE NORTH TO THE SOUTH DURING WINTER, AND SECURING TWO CROPS OF HONEY AND A HUNDRED PER CENT INCREASE.

FOR some years back we have had a dream of moving bees from the North, just at the approach of winter, to a southern clime, where they can gather a part of their own food, and at the same time build up for increase. We expect to move a carload of bees from Medina to a location which we have bought of Mr. A. B. Marchant on the Apalachicola River, Florida. This yard will be situated remote from any other bees, at a point where it can secure the early ti-ti and (later on) the tupelo in March and April. We plan to put 300 colonies in a car, and with them take about 300 hives in the flat, with necessary frames and foundation, and a power extracting-outfit. We aim to build these 300 single-story colonies into two-story from the ti-ti and other early bloom. In order that they may have plenty of pollen we are selecting our combs having the most of it, and putting them into the hives. Pollen in combs, by the way, is a splendid asset for the bees. We are feeding up only enough to land the bees in Florida in good condition. On arrival we will feed if necessary. If not, we shall expect them to get their own bread and butter, and go into the business of raising baby bees. In order to get a bumper crop from tupelo it will be necessary to have rousing big colonies. The whole scheme, in brief, is to build these single-story colonies into two-story ones, secure the crop of tupelo honey in March and April, and, when tupelo is over, split up these 300 two-story colonies into 600 or 700 single-story colonies; load them in two or three cars, and arrive in Medina for the early fruit bloom. A man who is thoroughly familiar with the Apalachicola regions will go with the bees—Mr. Ernest Marchant, who has been in charge of some seven apiaries for us during the past season. He believes he can take the 300 colonies to the Southland, where he was born and reared, and where he knows the locality thoroughly, build them up, and come back with twice the number of bees, and it is not impossible. He figures that the tupelo crop (if we get it) will pay for the cost of the experiment, and give us, with the bees left at Medina, a total of something like 700 colonies by the first of May. If Mr. Marchant were not thoroughly familiar with the conditions in the Southland there would be a great deal

of risk; and there will be risk as it is. We expect to give occasional reports of how the plan works; for if it succeeds there is no reason why any beekeepers in the North can not increase their investment in the same way. For example, Mr. R. F. Holtermann has a capital of some 600 or 700 colonies—that is, capital that is tied up for seven months in the year, barely maintaining an existence. During that time they will consume a large amount of sugar syrup or honey. Now, then, suppose he takes this capital, goes south with it, builds the bees up, secures a crop of honey, then comes north, ready to take another crop. It is not impossible. Our two carloads of bees a year ago this spring secured a crop of tupelo honey on the Apalachicola River, and then came north and secured a fine crop of clover and basswood. In other words, the same colony (not the same bees) will be on the job practically ten months of the year instead of four or five as now.

As already stated, we bought out a location on the Apalachicola River that has already made good. It is remote from any other beekeepers; and even if foul brood should develop, which is altogether unlikely, there will be no danger of transmitting the disease to other apiaries. All of our bees in and near Medina have been thoroughly inspected by our State inspector; and when next May arrives, all our bees in the South will be moved northward. Experience shows that we can move bees from Florida to Ohio for a little less than \$1.00 a colony. This includes freight and all other expenses of a man accompanying in connection with the moving.

Of course, this whole scheme may prove to be a grand fizzle. There may be a failure of ti-ti and tupelo; there may be a failure of pollen, and that would be as serious as no nectar. The weather might be bad. A flood might sweep the bees into the river; a railroad wreck might play havoc with the whole proposition; a thousand and one things might happen. They are all possible; *but we are going at this thing as if we were going to succeed.* Our experiment of securing two crops, one in Florida and one in Ohio, with two carloads of bees two years ago was a success. Mr. A. B. Marchant secured the tupelo honey before he delivered the bees to us. We moved them north, and caught the clover, and made 50 per cent increase. This time we hope to catch both crops, north as well as south, and get 100 per cent increase to boot. It's a great scheme if only *half* our dream comes true. In the mean time our readers shall have the benefit of the failure or success by reports from the field.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

THE tariff on honey is now ten cents a gallon instead of the old rate of 20 cents. I don't believe the change will make much of a dent in the business.

C. F. BENDER has given the key to a troublesome puzzle. The Root Co. found that it killed queens to keep them in cages of wire cloth not painted, and I never found any harm come of it. Mr. Bender explains that the Root Co. used galvanized wire cloth, while I used bright tinned wire cloth.

"OTHER things being equal, the highly fecund strain will produce a proportionately large amount of surplus," p. 605. But the trouble is that "other things" are *not* equal. At least I think that has been the rule here. When I've found a queen of fecundity above the average, industry or some "other thing" has not been equal to the average, so that, while a fourth more brood has been reared, a fourth less honey has been stored.

A. I. ROOT, let me endorse your advice to take care of the teeth, p. 657. Especially does that apply to the young. When I was a youngster I got into the habit of brushing my teeth, and now at 82 I have 29 fairly serviceable grinders, and ready for a chewing match with you any day. If you young folks can't brush your teeth after each meal, at least brush them after the last meal of each day, and not allow food to be decaying all night long between and on your teeth. Then you won't need store-teeth at 40 or 50.

LOUIS H. SCHOLL, p. 615, speaks of the loss of time caused by many bees foraging over the same ground near a large apiary, and others having to go a great distance from home. I wonder just how much bees crowd one another. It seems natural to think that near home it would always be crowded; but is it? If a piece of honey is thrown out, the bees will crowd upon it, but do they crowd upon the flowers? And if not, what wonderful knowledge is it that tells the bees just how to distribute themselves over the ground so as not to crowd?

G. M. DOOLITTLE, aren't you letting the drones off a little too easily, p. 603? A square foot of drones occupies the same square space as a square foot of workers, but you forget the thickness. I've just measured a new comb containing sealed drone brood, and it is $1\frac{1}{4}$ inches through. A similar worker-comb was 1 inch through. That makes drone-brood occupy 25 per cent more cubic space. Add to that the 14 per

cent longer time that drone-brood requires, and it makes a square foot of drone brood cost 39 per cent more than a foot of worker brood.

"HAS it been proven beyond doubt that there is any advantage in cutting alfalfa before it comes into bloom?" p. 633. I don't know how it is out west, but I do know that there is no doubt about it here. Wait till it is all in bloom before your first cutting, and the young shoots from the bottom (which shoots make your second crop) will have grown so high that they will be spoiled at first cutting, or else you must set your sickle-bar so high that you will not get all of the first crop. Besides, I think that, if you waited for full bloom at each cutting, you'd get about one crop less in a season, and so less hay. It is not believed here, as stated on p. 656, that cutting before bloom gradually reduces the tonnage, and eventually kills the plant altogether. The thing most blamed for killing is the failure to apply periodically a dressing of two tons of ground limestone to the acre. [We shall be glad to get more light on this question. Perhaps some of our subscribers in the West can give us the information. If so, our columns are open.—ED.]

MRS. Y. N. WESGATE asks, p. 620, whether some man can't devise an easier way than wiring frames. Why not try foundation splints? With them I don't use wire at all. [Foundation splints are perfectly satisfactory for the prevention of sag in foundation or in combs. We know that combs, even after they are drawn out, have a tendency to stretch vertically. This stretch occurs usually in very warm weather during a rush of honey. Splints will stop the elongation of cells on a vertical line; but they will not prevent combs from falling out or breaking out, during the rough handling of extracting time, like wires attached to the frame. You are a comb-honey producer, and, of course, experience none of the troubles of the man who produces liquid honey; but if you go into some large extracting-yard where combs are being handled in a wholesale way we believe you will become convinced that nothing short of wire secured to the frame itself will be satisfactory. Some one, perhaps yourself, suggested having the bottom-bar split so the splints can be placed between. If both top and bottom bars split so that the splints can be rigidly secured to the frame, they might prove satisfactory to the extracted-honey man.—ED.]

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

A few days ago I was surprised to see a bee down on the ground busily working on the fallen bloom of the date palm. There were dozens of them up on the bloom stems, but this fellow was evidently finding something to pay him for his labor among the fallen thousands.

* * *

I have just enjoyed a visit from my friend M. H. Mendleson, of Ventura. I doubt if there are a dozen beekeepers in the United States who are as well informed on all lines of the industry as he is. With over forty years of constant work he has had an experience that the majority of beekeepers will never enjoy. He has faced the ups and downs with the seasons; is an experienced producer of both comb and extracted honey, and has buyers standing with cash in hand for his comb product. His honey has won its reputation on merit. It takes years of careful work and honest dealing to gain such a reputation.

* * *

In the Aug. 1st issue I read of the capture of two swarms by J. W. Stine, one in a nail-keg and the other in a sack. I have frequently carried swarms in a sack, but about the most novel scheme I ever knew of being used was by a young lady returning from town on horseback, without a thing in the nature of a receptacle to put a very large swarm in that chanced to be on a bush by the roadside. After some deliberation she decided to make a hiving-bag of her petticoat; so she loosened it, stepped out, tied a string tightly around the top, then slipped it over the bush and swarm, tied another string tightly below the cluster, broke off the bush, and went home with her prize.

* * *

I was much interested in Wesley Foster's account of how his Uncle Oliver soaked his hive lumber in oil before nailing. There are a few of those old timers who believed in doing things thoroughly, with the idea that it would pay, and they were correct. Many beekeepers in this part of the State will remember my uncle, J. K. Williamson, who was a beekeeper for over twenty years; but who is now located on a small ranch in Mendocino Co. He always soaked the ends of his hive pieces in linseed oil, and carefully painted all joints before nailing. Many thought it a waste of time and money, but I am now using some of his hives that have been in use for twenty years. They are still in excellent condition.

THE ADVANCE IN THE PRICE OF HIVE LUMBER.

There was a period in the history of our country that might be called the virgin-soil period. That period has about passed, and is giving way to modern methods. This period includes the period of the virgin-soil farmer who could raise good crops with very little equipment or expense, because the soil would produce year after year if the farmer would only keep the weeds down. But now the soil is becoming worn out, requiring crop rotation and scientific methods of treatment. With modern methods of handling a crop, much more machinery is required than of old, enabling the crop to be handled quickly and cheaply. How about beekeepers? I wonder if there are not many of us who are virgin-soil beekeepers. We get along well while the seasons are good and every thing is prospering, there being little to do but to extract and to melt up the wax; but in a season like this, when the supply of bees as well as the stores are small, and the colonies must have individual care and careful watching, we begin to wonder if it will be worth while to spend money for feed for the bees.

The virgin-soil farmer is feeling the same way, for he too is being forced to give much more care to the old farm than when the crops came regularly with little effort. Do not let the bees die. If you have neither the time nor inclination to give them the proper care, why not sell out and save yourself a loss? Does the average beekeeper know that the hives that he purchased a few years ago are worth more now than when they were new? I met a friend on the street yesterday, who is the manager of one of our local lumber-yards. After a short conversation I asked him the price of various kinds of lumber, and his answer took me greatly by surprise. Sugar pine that a few years ago sold for \$30.00 a thousand is now worth over twice that amount; clear sugar pine that my uncle paid 6 cts. per foot for four years ago for hive covers is now selling for 15 cts. a foot. Hives, if they have been well taken care of, are worth twice what they were a few years ago; and those who think of selling their bees and location with the idea of starting in new, would do well to figure closely on the cost, lest they be fooled out of some money. A few years hence our present methods will be considered antiquated. The time will come when apiculture will be taught in all agricultural colleges, and the science of the business will be one of the features of instruction.

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

For the past week I have had the unusual spectacle in my apiaries of seeing great clusters of bees hanging out over the fronts of the hives. I have never seen this before in October, and may never see it again. The unseasonable heat is, of course, responsible for this, and in colonies that had been fed heavily the bees were outside of the hives as in hot midsummer weather.

* * *

In my notes for Oct. 1 I said that nearly all parts of Ontario had the long prevailing drouth broken by copious showers. This was true at the time of writing; but the few showers that came at that time ended abruptly, and since then no rain has fallen. At this date (Oct. 10) every thing is as dry as a bone, and we have been having torrid weather, with temperatures up in the eighties—an unusual condition for October here in Ontario.

* * *

Most of my feeding is done, but there are a few colonies yet to feed. These were examined to-day, and in every case the queens were starting quite a large brood-nest, only eggs and very young larvæ being present, showing that the unseasonable weather is responsible for this condition. Too warm weather at this time of the year is not the best thing for helping wintering conditions in our latitude; but quite likely we shall soon get an extreme change, and this late brood-rearing will then be checked.

* * *

Secretary Pettit reports that the Ontario Beekeepers' Association now has over 1300 members. An aggressive campaign in the way of organizing new county associations is largely responsible for the large increase in membership, as the majority of the members of the local associations join the Provincial association too. Whether the usefulness of the association will increase in proportion to the increase in membership is a question; but according to the old motto, "In union there is strength," the more powerful the association is in numbers, the greater chance it should have in the matters of securing legislation and in forwarding other interests necessary for the industry. That work of that nature should be expected of the association in the future more than in the past is the opinion of many.

* * *

The convention of the Ontario Beekeepers' Association will be held in Toronto, Nov. 18-21. Of course we are expecting a

large attendance, not only from Ontario but from the States across the border. All the counties near Toronto have this year had a fine crop, and this will, no doubt, be a stimulus to many to attend, who otherwise might not put in an appearance. It is needless to say, the officials of the association are very anxious for a good attendance, and certainly anticipate having a pleasant and profitable reunion. A hearty invitation is extended to our friends "over the line" to come and visit us; and it will be a genuine disappointment if a number of them do not put in an appearance. The convention is at a time of the year when beekeepers, as a rule, are not busy. So, pack your grip and take a trip to the Queen City of Canada, not forgetting to bring your wife with you.

* * *

Some time ago I noted that Mr. McKinnon, of St. Eugene, Ont., claimed that his Italians worked as far away as four miles from home. In common with previous claims of this nature on the part of others I rather doubted the truth of the matter, for while I would not question Mr. McKinnon's veracity, yet I felt that there was a possibility that he might be mistaken. Just a few days ago he wrote me that he would like to have me there to prove that he was right; that at that time his Italians were cleaning up a batch of blacks about four miles away, and, in addition to this, they were cleaning up the honey from a bee-tree that had been cut down, which was $3\frac{1}{2}$ miles distant. I think I shall have to admit that his claims are correct; but for the life of me I can not tell why my bees acted differently some years ago. At that time there was an abundance of buckwheat about four miles distant; and while bees in that district would store a surplus our bees would not get a smell of buckwheat, and there were Italians in the apiary from different breeders in the States, some of Doolittle's strain at that, and you know friend Doolittle is right in line with Mr. McKinnon on the question of bees going a long way for nectar. While on this subject I must frankly admit that this year we had bees travel four miles; but it was under conditions different from those we have ever had before. The Lovering apiary is two miles from the water, and the bay is two miles to the opposite shore. Thousands of bees flew across this stretch of water, and I rather surmise that, in case of a head wind blowing against loaded bees, this long fly over the water would be detrimental rather than otherwise.

Beekeeping Among the Rockies

WESLEY FOSTER, Boulder, Col.

Fair time comes too close upon the honey crop to give beemen time to exhibit as they should; but the advertising of honey is a matter that needs serious thought.

* * *

Bees were poisoned badly this year in Delta Co. and parts of Montrose. Little of this seems to have come about by spraying in blooming time, but the late sprays falling on clover when the bees were working on it caused the trouble.

* * *

If a number of nuclei are started during midsummer they are always very handy when fall comes, to use in strong colonies that are queenless. I always have a few queenless colonies in September and October, and these nuclei save the day in very good shape.

* * *

PECULIARITIES OF THE SEASON.

This year colonies of bees occupying two full-depth Langstroth bodies had, without exception, more brood sealed and hatching than single-story colonies. It seems to be during late September and early October almost an invariable rule that colonies occupying single bodies had little if any brood. Many had a patch of eggs, but no larvæ or sealed brood, showing that the queen apparently had difficulty in shutting down her egg-laying. Colonies with young queens of this year's rearing have more sealed brood than the others. Our fall flow has been better than common; breeding has been ample, and our colonies will go into winter with good stores, and large numbers of young bees.

The last two weeks have brought us several very good rains, and killing frosts have been later than usual. Sweet clover and alfalfa have been wonderfully helped by these late rains. These rains have been in the valley; snow has fallen on the mountains in some parts of the West, so that prospects for next year look encouraging. The late rains will also probably destroy many of the grasshoppers' deposits of eggs in the ground. Dampness is very destructive to them.

* * *

GEORGIA VS. COLORADO.

It is interesting to read of Mr. Wilder's success in beekeeping in Georgia, when one of our largest and most successful beekeepers in Colorado came from Mr. Wilder's country because there were no opportunities

there. He told me recently that he probably would have done as well to stay in Georgia. What we should like to know of Mr. Wilder is whether there is flora enough to support several hundred specialist beemen with three hundred to three thousand colonies, or will Mr. Wilder own all the bees and have all the capable beekeeping timber among the darkies working for him before some of the rest of us get settled there?

Two hundred thousand pounds of honey is nearly as much as we can produce in our county, and here it takes twenty-five men and a dozen automobiles to do it. But we raise comb honey almost exclusively. For fear that Mr. Wilder will get all the good beemen trailing toward Georgia, I will say that Colorado still has opportunities, and we have the climate, the flora, the *good roads*, and a fine class of people. Many beemen are making their living from keeping bees, and do not follow it as a side line.

* * *

SWARMING IN COLORADO.

This has been another swarming year, violating all rules of good behavior that we generally expect from "mile-high" bees. We lost a good many swarms, and the demoralization has caused the loss of a good deal of honey. The bees swarmed with or without cells or eggs in them. The only thing that seemed to prevent it was to kill the queen. We had to shin up trees as the editor of GLEANINGS did, but perhaps we had better success in catching the queen at the entrance as she came out. Even though only a virgin, I had very few get away from me. One needs to be quick if he wishes to catch a queen the minute she stops to look which way to take wing. If he misses a virgin on the first grab, the chances are that she will get away; and then if she is not caught there are probably other virgins with the swarm. But if I caught the prime swarms I did not have any second swarms, and very few of them did I have this year as it is.

The editor has come forward with an almost sure cure for swarming by the use of inch blocks. We in Colorado have been envied for our freedom from swarming troubles, but we had them this year and last. The plan of Mr. Vernon Burt is as old as the hills (almost), and is good; but, oh don't give it out as a cure or even a preventive! it will delay swarming sometimes until a few cold cloudy days come, and the flow lulls; then the bees tear down the cells, but the cool weather or the lull in

the flow is the preventive, not the blocks. I have used the blocks, and do yet; and I go further and shove the covers and supers backward and forward, and the swarms leave just the same. The ventilation surely helps, but I could have shown colonies so treated swarming by the dozen this past summer. Bees swarmed here right through August up to within a week of the closing of the flow, and we surely had a time with them.

* * *

MAKING INCREASE IN AUGUST OR SEPTEMBER.

In my Harmon apiary I had sixty extracting-bodies of full-depth Hoffman frames that were about full of honey. In my other apiaries, and also in the Harmon apiary, the bees were still swarming late in the season, so that I had available some fine cells for starting nuclei. I wanted a lot of young queens for what increase I got, so I started sixty nuclei in my Crosby and Superior yards of one or two frames each; and early in September, when these queens were laying, I took off my extracting-hives at the Harmon yards and hauled them to the nuclei apiary, giving one or two full sheets of foundation or empty combs for the queen to rear brood in to strengthen them for winter. The comb-honey supers were then coming off my surplus colonies, and most of these had more bees than they needed. True, many of these bees were old and worn out, but I used them just the same. I shook out one or two pounds of bees from one or more colonies into one of my tin covers, and over them tacked a movable screen cover. This gave the bees a space three inches deep and the size of the hive. In these covers I quickly moved a lot of bees to my nuclei in the other apiaries, and strengthened them. The moving was necessary to preclude the return of the bees to their own hives. The young queens had most of September for breeding up, and by this means I have been able to get some extra colonies of bees in prime condition for wintering.

* * *

BEEKEEPING IN THE PLATEAU VALLEY.

In the Plateau Valley beekeeping enters into diversified farming operations almost as much as alfalfa-growing. Nearly every farmer has his neat honey-shop close to the house. The apiary at one side or behind the house, some distance, is often a model of neatness. Few box hives are to be found in the valley, and foul brood is all but unknown—a small percentage only being found in the lower part of the valley around Molina and Mesa.

When I visited the valley early in September it was the rule to find the beekeeper-

farmer and his wife at work cleaning and packing comb honey ready for the market.

Comb honey is the sole shipping product of the apiaries, very little extracted being produced. The price secured has been from about \$2.40 to \$2.65. The honey is packed in 24-pound single-tier cases, with glass front or wood slides. Two grades are made, more attention being paid to weight than color. Considerable attention is given to finish in grading. The honey is sold through fruit associations at Palisade, Debeque, and Grand Valley, which are loading stations on the railroad, fifteen to twenty-five miles distant. The fruit associations charge 5 per cent for selling the honey, and pay for it when it is loaded into the car. They do not pay for the honey, however, until a sale is made, although they may have verbally contracted for it.

One thing I have noticed in various places as well as in the Plateau Valley: The produce dealers offer good prices for honey early in the season. The beemen haul in the honey to the warehouse, but the dealer or association does not generally sell until a car is about ready to load. Then if the price has fallen he tells the beeman that he can not pay so much for the honey. I have found this method altogether too prevalent. The beemen have ended this uncertain manner of dealing in some places, and it is time that it was ended in all. When one has an offer of so much for his honey he should clinch the bargain with a cash-down payment of fifty cents to a dollar a case, and then live up to the bargain and make the buyer live up to his.

The farmers, most of whom have some stock, told me that honey is their money crop. This is more generally true of the farmers in the Plateau Valley than in any other part of Colorado where I have been.

An incident will illustrate the prevalence of beekeeping. I went into the general store and postoffice at Plateau City to get a bill changed, and was handed a dollar among other change. It was so daubed with propolis that I could hardly see the eagle. Do you suppose the postmaster knew I was a beeman?

The winters are more severe in the Plateau Valley than twenty-five miles further down in the Grand Valley around Grand Junction, and the winter stores are more likely to granulate and cause winter losses. There is a great deal of waste land upon which sweet clover grows, which is the main reason for uniformly good crops. The greatest drawback, as I saw it, is in having to haul the supplies fifteen to twenty-five miles, and to haul the honey this distance to the loading station.

Conversations with Doolittle

At Borodino, New York.

MOVING BEES.

"I wish to know something about moving bees, especially the details connected with it, which are usually left out by those who write on this subject."

Much depends on how far bees are to be moved. In moving them to and from an outyard, from three to five miles away, I have been fairly successful—so much so that I never had any trouble by injury to the bees, to the horses, or to myself. I place the hives carefully on a spring wagon, just as they stood in the apiary, bottom-boards and all undisturbed, and cover them with a large canvas, such as is used to protect haystacks before their completion. In hot weather this way of moving bees requires a cool cloudy morning or the close of the evening. If the wagon is not overloaded, so that the springs hit, or the hives jostle together on a rough or stony road, the bees will hardly come out from the entrance.

Much depends on those who load the colonies. If they can not pick the hives up and put them in the wagon so carefully that the bees remain quiet, or nearly so, it is better to use smoke until the colony is subdued, and then put them in the wagon without even so much as stopping up the entrance, and drive off with them. Naturally one would think that many of the bees would leave the hive and go away; but only a few will do this. One year I moved some bees in this way about fifteen miles. I started out with them on the evening of a very sultry day, over a rough road. A neighbor had bought them in the month of June, just before swarming, when the hives were full of bees, and we had no trouble in moving them. The hives were set about six inches apart, so that the bees from one hive would not be liable to run over into the neighboring hive on either side. When we arrived with them the larger part of the bees were on the outside of the hives. They were allowed to stay thus until the early twilight, when, with the use of a little smoke, we had no trouble in putting them on the stands.

But when bees are to be moved long distances it is better to prepare for this by giving ample ventilation, which is an important item in the successful moving of bees where they must be confined to the hive. This is always the case where they are to be shipped through any transportation company. I find a rim three inches deep, the same size as the hive, covered with wire cloth, none too much; and if the colonies are very strong, four inches is better. Put one of these on the bottom and one on

the top, and fasten securely. After trying many kinds of fastening I have found nothing better than lath, such as is used in plastering houses. For length, cut so they will reach from the top screen to the bottom one, being a little "shy," so that the ends will not catch against other screens or any thing on which they are loaded. Use four to each hive, nailing one at each corner to both hive and screens, this making a most secure method of fastening firmly both screens and hive-bodies. It gives even the strongest colonies plenty of ventilation, and plenty of room and space to cluster away from the combs of brood. In this way little or no loss occurs to either brood or bees.

With ample provisions by way of honey I have shipped bees to many of the Western States, and some to California, or nearly across the continent. Some claim that water is necessary, and it might be for shipments across the continent during July and August; but so far I have never used any, and have had no loss reported. In the front end of the bottom screen bore a $\frac{3}{4}$ -inch hole when making the screens. This makes an entrance for the bees, and thus allows putting the screens on several days in advance of the day of moving. It gives the bees a chance, too, to fly when they arrive at their destination, just as soon as the hive is set on the stand they are to occupy. Under these circumstances the unpacking can be done more at leisure than would be the case if the first flight were to come with the unpacking. To stop this hole when moving, use a cork or plug. I generally get a lot of dry corneobs, pushing a piece of the right size in the hole, and twirl it around until it wedges in tightly. The frame for long-distance shipments should be securely fastened in the hives, so that they will not slide together nor swing. Where self-spacing frames are not used, pieces of lath of the length of the inside of the hive can be used to fasten the frames securely, nailing one at each end (on top) down through the end of each top-bar and the hive. The nails should be long enough to reach into the wood of the hive from half to three-fourths of an inch. Now tip the hive up on end and stuff old newspapers in the bee-space between the ends of the frames and the end of the hive. If the hives are to be moved by wagon it is important to load them so that the combs run sidewise in the box, as the greatest strain on the combs is from the box swaying from side to side. When shipping by railroad, the combs should run lengthwise of the car.

General Correspondence

REMARKABLE COMPETITIVE EXHIBIT OF BEES AND THEIR PRODUCTS AT THE CONNECTICUT FAIR, HARTFORD

BY BURTON N. GATES

A most remarkable and unique apicultural display is annually made at the Connecticut Fair, Hartford. It is by far the most spectacular beekeeping show now available in the East. The management has an abundance of enthusiastic material available in Connecticut beekeepers. The beekeepers have an exceptionally interested fair management and well-equipped fair building, 75 x 50 feet. There is, moreover, an aggregate of \$500 in premiums. Consider what this means to the promotion of the industry when upward of 150,000 people attend the fair.

The large electrically lighted building with electric signs, of pavilion type, and accessible near the entrance to the grounds, is apart from all other displays. (See Fig. 1.) Thus the apicultural display is distinctly a feature. In contrast it is to be regretted that the honey show at some fairs is frequently merely an annex to the fruit or flower shows, or even to the poultry exhibit, which, of course, makes it less distinctive. The illustration shows a few of the attendants and exhibitors.

At Hartford the competition is "open to the world," with this restriction—that competitors must be or become members of the

Connecticut Beekeepers' Association. This applies with exception to the section designated "Culinary," comprising cookery in which honey is used, and to the "Displays by Novices."

Another distinctive feature is that the premiums are offered and awarded by the Connecticut Beekeepers' Association, of which Mr. A. W. Yates is the present Chairman of the Committee on Fair. In this way the best interests of beekeepers are fostered; also the excellency of the display may be attributed to this provision. The Association, being incorporated, receives from the State a bounty for premiums, which accounts for the fact that, since 1908, when the Association began to make its competitive displays, the premium awards have advanced from \$35.00 to \$500. This is a surprising and admirable development in six years. The earnestness in the display of products is further maintained by a slight entry fee of 25 cents for each entry in practically all classes.

At the present display, made the week beginning September 1, there were upward of twenty competitors. The extent of the displays may be judged from the fact that there were approximately fifty colonies of bees and from eight to ten tons of honey on exhibition, besides displays of cookery, wax, and products not specifically called for in the premium list. Another feature of the Association's effort is the acquainting of the public with honey. Concessioners have for sale wax, honey in all forms, and honey sandwiches. It is estimated that the sales of concessioners may be as high as \$100 on the large days of the fair. A fee for space is required from each concessioner.

Still another feature which has especially interested the public is the daily manipulation of bees in a cage. Such demonstrations, as beekeepers know, attract large audiences. This handling of bees may occur several times a day, and is scheduled according to the attendance at the fair. The management

FIG. 1.—Beekeeping, Exhibit Hall, Hartford, Ct. The pavilion is 75 x 50 feet, with an open front. Some of the concessions are shown grouped in front.

FIG. 2.—The Concessioners' Exhibit at the Hartford Fair.

is also making a feature of the display of commercial supplies for beekeepers. Some of the concessions may be seen in Figs. 2, 3, 4.

The premium list is exceedingly liberal, and is a true inducement to the beekeeper to make a display. For instance, for each of the races of bees with their queen, three premiums are offered, being respectively \$10.00, \$8.00, and \$5.00. Liberal premiums are also offered for queen-rearing outfits, being \$16.00, \$10.00, and \$6.00. In the classes of honey, the premiums are respectively \$10.00, \$8.00, and \$5.00. For the largest and most attractive display of honey shown, the premiums are \$24.00, \$16.00, and \$8.00. Part of one of the large honey displays is shown in Fig. 4. The sums of \$10.00, \$8.00, and \$5.00 are offered as premiums for the best displays of beeswax, of which there must be at least ten pounds. A sweepstake of \$25.00 is offered. This was won by Mr. W. K. Rockwell, of Bloomfield, who also took first premiums on Italian, golden, Carniolan, and black bees, the best display of the different races, and the best display of queens in labeled cages. It must have been some satisfaction to Mr. Rockwell to realize awards amounting to \$130.00. Other competitors secured respectively \$71.00, \$61.00, \$43.00, \$30.00, and lesser amounts.

In the honey classes, Mr. H. W. Coley, of Westport, secured the first premium on the best ten sections of comb honey, the best section honey packed for market, the best candied honey, and the largest and most

attractive display of honey in general. An award of \$10.00, first premium, was made to Mrs. H. O. Havemeyer, of Stamford, on dark extracted honey. An award for twenty-four jars of chunk honey was made to Mr. C. H. Clark, of Cobalt, of \$10.00 as first premium.

The writer personally examined the entire displays, and can not but express satisfaction in the quality of the material exhibited, and the difficulty which the judge, Dr. D. Everett Lyon, must have experienced in making awards. The general excellence of the displays show that

the beekeepers have learned what competition means. But few restrictions are prescribed by the Association. As might be expected, exhibitors can compete for but one premium with the same exhibit, excepting, of course, sweepstakes. The honey, excepting candied honey, must be of the current season's crop; wax must not have been previously exhibited, and all honey and wax must be a product of the apiary of the exhibitor. The Association also emphasizes in displaying comb honey, the perfection of filling and capping, the neatness and completeness of cappings, and the general appearance for market purposes. More and more emphasis is being laid upon freeness of sections from propolis; therefore the beekeepers have learned to clean their sections. Extracted honey is judged for its body and flavor, clearness, cleanliness, and general appearance of marketability.

Inquiring of the management, the writer was told that, in the last few years, exhibitors have learned to avoid mistakes, and how to exhibit. Nothing like competition will bring about closer grading and selection of products. For instance, those who have had the most experience in displaying have learned to bleach their sections and grade them for evenness, in weight, capping to the wood, and color; they have learned to use new shipping-cases and bright sections. Moreover, the cases preferred expose the entire section. Sections of full worker comb, or the avoidance of drone comb, is another feature. The management also emphasizes

that all honey displayed must be glazed, or in cartons which are bee-proof. Consequently the type of carton with a peekhole or other opening through which bees can enter has been prohibited. The larger displays are made on glass shelves so that the light can penetrate on all sides. This is an important feature, and the exhibitors told the writer of their particular effort to avoid shading any part of their exhibits. Some effort is made to bring electric lighting to the rear of the displays of honey.

The management and individual competitors are agreed in an effort to vary from year to year their displays, thus avoiding monotony and adding to the general interest of this department of the fair.

Seldom are fifty colonies of bees seen in one competitive exhibition. It is expensive to show full colonies, and the writer raised the question how beekeepers could be induced, especially in the fall, to make such an extensive exhibit (Fig. 5). The reply was, "They are small nuclei." This is a far less tax on the colony, is no great expense to the beekeeper, and is not especially hard on the bees. To show full colonies would mean that there would be but few competitors. It is by using the nucleus, with about half a frame of bees, that this excellent and large exhibit has been made possible. It also enables the queen to be found early. It was noticeable, however, that but few of the colonies displayed drones. This was brought to the attention of the exhibitors, who agree that, in the future, one of the requisites in displaying bees should be the including of drones as well as the queens and workers.

In competition of the black bee, considerable discussion was created over the marks. Mr. Allen Latham emphasized in the true black type the absence of "chocolate markings," and, if possible, the blackness of the legs, especially of the queen. Throughout the displays of bees there was close competition. Some of the more unusual races, such as Cyprians, Banats, Egyptians, etc., were absent. The first prize

FIG. 3.—Arranged in front of this concession are shown some of the nuclei entered in competition at the Hartford Fair.

in each of the classes of bees was won by Mr. W. K. Rockwell.

From the educational standpoint, the peculiarly important feature of the bee show is Section 3, "Competition for Novices," in which it is prescribed that "no one previously exhibiting or receiving premiums will be considered in this department." These excellent provisions annually induce new beekeepers to come out for competition. While the premiums in this department for section honey, light and dark extracted honey, chunk honey, and two pounds or over of beeswax, are respectively lower, \$3.00, \$2.00, and \$1.00, it prevents the smaller or newer beekeeper from feeling that he has no possible chance of winning in competition with the more professional class; yet the novice, of course, is privileged to display in competition with the experienced beekeepers. Mr. Walter Beeman, of Bloomfield, seems to have been the important novice exhibitor this year, taking largely the first premiums in each class. Mr. J. E. Wallbeoff, Wethersfield, came in for the second premiums, largely. It has been noticeable in most honey shows that these excellent provisions for the novice are not provided. This is a marked step in advance for the promotion of interest in beekeeping.

While the culinary section of the exhibition was, perhaps, less extensive than the other departments, the judge is quoted as having expressed his opinion of the superiority of the honey muffins, cookies, cakes, canned fruit, and pickles displayed. The

FIG. 4.—One of the honey displays at the Hartford fair is shown at the rear, in front of which is grouped a collection of competitive colonies. The shelving for the display of honey is of glass.

exhibitors called special attention to the canned fruit, which in every way rivals fruits canned with sugar. It is to be regretted that beekeepers are not making more of this feature of the utilization of their product.

With the public, the sale booths, where honey-sandwiches are offered, seemed to attract considerable attention. The vender of these luscious sandwiches warns the novice salesman against possible disastrous results through a sudden influx of robber bees. The booths are specially constructed for handling the honey; being immaculate in appearance, the prospective purchaser is convinced of the cleanliness of his sandwich. The part of the booth where sandwiches are prepared is entirely enclosed with netting to prevent the access of "robbers." The secret of success is, of course, the prevention of the first robber bee from returning to the hive with a load. The sellers of honey-sandwiches elsewhere, to the writer's knowledge, have been forced to

close up their stands because robbing had gained such headway. Those selling honey at a fair can well remember the remedy for checking the approach of robbers. A weak solution of carbolic acid sprinkled about the booth will do much to repel them. Everybody being anxious to "see the queen," one of the calls of the honey-sandwich man is, "Come and see the queen!" He may have a queen in a mailing-cage or in a nucleus. Attracting his crowd by this means, he then induces them to try some honey. Tactfully, too, he urges the visitors to go among the rest of the displays. In this way many a person who is not familiar with the taste of honey acquires a liking for it. In talking with people around Hartford, the writer had but to mention the bee show when he was asked with enthusiasm, "Did you have a honey sandwich?" It is thus evident that the honey-sandwich is a key to the venture.

Amherst, Mass.

FIG. 5.—Another view of the honey displays shown in FIG. 4. A long range of about fifty colonies of various races is shown at the right. In the rear of these comparatively small displays is a demonstrational cage for the handling of live bees.

FOUL-BROOD INSPECTION IN IDAHO

Some Interesting Details of a Bee Inspector's Life

BY W. E. RAMBO

Anent your account of foul-brood inspection in Ohio, p. 516, Aug. 1, a similar experience in Idaho may be of interest. I bought two colonies in the spring in box hives at half price, intending to transfer and build up a small apiary. I set standard hives on top of them till the queen should begin work. When that took place in one, I cut out the old combs and found a bad case of foul brood. This induced me to transfer the other colony at once. I found it still worse. The first colony produced a fine lot of sealed brood which became badly affected by hatching time, necessitating a second transfer. Both colonies are doing well now, but will accomplish nothing more than preparation for winter.

I began to inquire, then to suspect, that foul brood was very prevalent. I wrote the State Inspector. He sent Mr. E. J. Johnson, of Fruitland, inspector for District No. 6, which includes Boise County and the Payette Valley. I accompanied Mr. Johnson on July 21 and 22, mostly on foot. The experience was an eye-opener. Many colonies were in boxes. Many that were on loose frames had been put in without starters or foundation, and the combs so badly crossed that inspection was practically impossible. The law in Idaho condemns all such, giving the owner five days within

which either to transfer or destroy them. Of hives that could be inspected, over 10 per cent were found infected with foul brood. Here are figures kindly given me by Mr. Johnson:

In fifteen days' inspection, between May 28 and July 31, 965 colonies were inspected. Of these, 171 were condemned, being in box hives, and 103 for foul brood; 691 were passed. Those in boxes included nail-kegs, a wooden jacket from an oil-can, old tubs, soap-boxes, stick gums, etc. I suspect that many of these had foul brood. The common excuse for conditions was: "This goldurn swarm lit out there on that there plum tree, 'n' I jes' shuck 'um into that nail-kag. I don't know nothin' about 'em, 'n' I don't care a durn fur 'em. I jes' cal'ated I'd sulphur 'em in the fall and git some honey t' eat; but 'f your s' durn pertickler about ut, I'll jes' kill 'em right now. I can't do nothin' with 'em; they jes' sting me, 'f I go in a rod uv 'um, 'n hit's pisener 'n' rattlesnakes." Well, may be 10 2-3 per cent is not bad; and I suspect inaccessible hives will account for at least that much more. About 225 were transferred; 50 were burned; 110 places were visited, and the mileage was 385.

Mr. Johnson told me that he definitely knows of 1700 colonies which have not been inspected. Of course, there are many unknown. He passed by the larger apiaries which appeared to be well cared for, and where the owner knew and was fighting foul brood. He argued (rightly, I think) that

more danger is to be suspected in the small bunches stuck around farms and in boxes by people who have no knowledge of bees.

"But why neglect any?" you say. A passage or two from the State Inspector's notice to Mr. Johnson explains: "There being sixteen inspection districts in the State, and the money appropriated for this purpose having to be allotted to the different districts, your district was given the following amount for bee inspection for this year: \$150 for districts Nos. 6 and 7." Mr. Johnson understands this to mean \$75.00 for district No. 6, said district being perhaps one hundred miles long and a county wide, the Payette Valley alone being something like 10 x 30 miles. For lack of funds, Mr. Johnson has not seen half of the Payette Valley, and nothing at all of Boise County. Again: "I also note what you say in regard to there being no bee inspector in that district before. Heretofore there has been no request for a bee-inspector in that section. That is the reason why there has been no bee inspector in the past."

It seems a pity that foul brood should render beekeeping next to impossible here; for natural conditions are all but ideal for the business. The fruit-bloom begins by the first of April—very often much earlier. This is soon supplemented by dandelions; then white clover; then alfalfa; then white sweet clover. These three last till freezing weather, and are in abundance along the river banks and irrigation ditches, where they are kept perpetually green and blooming through the long season by reason of moisture at the roots. Alfalfa is usually cut when in bloom; but the borders remain, and it grows, like sweet clover, in all waste places. White clover is abundant, and never ceases to produce nectar, apparently.

Following is the performance of a single colony: On July 28 nearly half a bushel of hybrids were found on a fence-post in the edge of town. I was away from home, and my son hived them in an oil-box. We brought them home that night. July 29, near noon, I put them into a ten-frame hive with full sheets of foundation. July 31 the sheets were all drawn out, and partly filled with honey. August 1 the queen was laying in a limited space; frames heavy with honey, bees hanging outside at night. August 2, put on extracting-super with inch starters. August 8 queen laying in five extracting-frames which are almost fully drawn out and filled. August 9 removed two frames of honey, and replaced by two full sheets of foundation and put a section-super on top of the extracting-super. August 15, found the queen back in the brood-nest; put the section-super under the extracting-

super. August 21, brood hatching; August 26, working nicely in sections; brood-nest crowded with honey. August 27, removed the frame of honey and replaced with a full sheet of foundation in the brood-nest. August 29, bees seem crowded for room; put another super under the others.

Mr. Johnson returned on August 6 to check his former inspections and to inspect other colonies. This time he came with his wife in his automobile. He was able to take me and my wife and daughter all over the neighborhood. That night his auto stood in our dooryard, and, after having supper and an evening with us, they slept in a neighbor's house. The next morning he very kindly invited me to go home with him. The trip of about thirty miles was a great delight. We went by the "South Slope" fruit-farms and inspected a number of colonies—mostly in ramshackle boxes and gums. We met the proverbial pessimist, who declared his bees were all right, and that the inspection was a "graft" intended only to provide fat places for the "friends" of the legislators. But here is where Mr. Johnson shone best. He gave Mr. Pessimist no chance to get in a word, but talked him into silence, in the mean time digging out enough of his combs to illustrate his lecture on foul brood, and leaving his antagonist wide-mouthed with amazement and chagrin. From the fruit-farms we passed through a stretch of waste land, ruined by seepage and alkali. This changed near New Plymouth to splendid grain and apple country, which continues, I am told, all the way to the Snake River at the mouth of the Payette Valley.

THE INSPECTOR AS A BEEKEEPER.

Mr. Johnson is an old Colorado beeman. He moved to Washington a few years ago, but found conditions unfavorable. His home is now at Hillsboro, Oregon, where he spends the winters. But he moved his apiary to near Fruitland, Idaho, a few years ago. There he found two acres in sagebrush, with one canal on the north, another on the east, and the Payette Valley railroad on the south, with only the bank of the canal on which to get to the main road. This land was too high to be watered from the supply ditches, though it was almost level. Mr. Johnson bought it cheap, then cleared it; then got permission to connect a neighbor's waste ditch with the plot, so he has plenty of water free of charge. Then he widened the canal bank as far as he could go on the south side, and then bridged it, widening the north bank thence to the road. There he is in a picturesque, secluded spot, with great fields of alfalfa all about and with tangles of sweet clover along the canals and railroad. There he spends his

summers in a sleeping-tent; he has a shack with a kitchen, a cased honey-room, an automobile-room, and a general storeroom and workshop. He is an enthusiast with bees; has his own way for doing every thing, and violates most of the rules of the books. For example: He does not use queen-excluders; he says, "If the old lady wants to lay in the extracting-combs or supers, bless her heart, let her do so." In extracting, if he finds unsealed brood, he leaves it till it is sealed; then extracts the honey and distributes the brood to where it is needed in other colonies. He uses no followers or self-spacing frames or springs; wedges his sections in with wood from spoiled sections. In handling supers he does not try much to save bees. "A few bees smashed is cheaper than time." He has about 250 colonies, all hybrids. "The blacker the better." They are a mixture of almost every standard breed produced by the introduction of queens at different times. He says these hybrids are the best hustlers, and make the whitest honey. The stock for his apiary was formed by a lot of hybrids from southern Texas which he shipped to Colorado years ago. Some of Mr. Johnson's bees are as cross as hornets. They boiled out everywhere with their tails up sizzling with venom like rattlesnakes. He raises his own queens in nuclei formed from combs with queen-cells on them. These queens are of all shades imaginable. We found one whose head and thorax were clean of all hairs, polished, and black as ebony. That part of her looked more like a black beetle than a bee. The abdomen was of a brownish-yellow color with prominent black rings shading almost into each other along the back. Mr. Johnson said he had never seen a queen like her.

He boils his waste combs in a big tank. When cold he dumps the whole on the ground and throws the chunks of wax, dead bees, and slumgum into gunny sacks and keeps these in the shade of a tree until the season is over; then he renders all in proper manner, using the wax-press. He says the bees don't disturb the dirty cakes in the sacks.

He put up arguments for the eight-frame hives that were unanswerable by an amateur like myself. His record for last year for 250 colonies was between 11,000 and 12,000 lbs. of honey, 5200 lbs. of which was bucket honey, composed of chunk and extracted. His comb honey was all sold to a shipper from California. The bucket honey was shipped to Portland, Oregon, and peddled out; prices were in the neighborhood of 12½ cents a pound all around.

I was very much interested in a device of Mr. Johnson's own invention. He calls

it an "Indicator." With the compass he draws a circle two inches in diameter on the back end of each hive. Through the center he draws a perpendicular and a horizontal line. At the intersection of these lines with the circumference, and also half way between said intersections he drives tacks, eight in all. This forms a kind of dial. For a hand he uses a piece of soft galvanized wire, No. 12. He bends a loop on the end of the wire by means of two headless nails driven close together in the bench. Then after the bend he cuts the wire something near an inch long and fastens it in the

center of the circle with a ¾-inch screw, tightening just enough to remain set in any position. Then he makes an enlarged chart to hang in his workroom for reference. On this he writes at every tack a certain condition of colony. Beginning at the top, for instance, he will write "O. K.," the next tack to the right will be "Diseased;" the next, "More room;" the next, "Queen-cell;" the next, "Weak;" the next, "Young queen;" the next, "Queenless;" the next, "Attention." For this device he claims the following advantages: 1. No book or pencil is required; tacks and circle can not be erased, and will show the same after the hive is painted. 2. It is not in the way in tiering up and shipping hives, even when the latter are taken apart and shipped in the flat. 3. Never wears out. 4. Cost for labor and material is only about three cents to the hive, and they can be made at home. 5. Can be used for any purpose, the chart being changed according to purpose or whim of the beekeeper, or for different seasons. In a large apiary, Mr. Johnson does each separate act on all hives before beginning the next act. For instance, he sets his compass and draws circles on all hives; then he returns and draws lines in all circles, then drives tacks in all; then fastens the wire indicators. I enclose an illustration of the device. Mr. Johnson says

Bottom-board with large screen-covered opening for providing additional ventilation in winter.

he has tried every thing, and likes this best of all. In use, he makes periodical inspections of his apiary, setting the "indicator" on each hive to show the condition inside. At the end he has only to pass through and supply the needs of each, having no concern for those indicated "O. K.;" and no hunting for records.

I was with Mr. and Mrs. Johnson from 4 P. M. till 2:30 P. M. the next day. They made every moment a delight. They are good Baptists, and spirited, whole-hearted people. Mr. Johnson says he will clear the Payette Valley of foul brood. They drove me in their auto to Fruitland for the evening train. As I sat by the car window and watched the panorama of field and orchard and canal and river and mountain rush by me I felt that God is good and life is sweet, and I had received almost a college education in beekeeping.

Emmett, Idaho.

WINTERING OUT OF DOORS WITH A SCREEN-COVERED OPENING IN THE BOTTOM-BOARD

BY J. W. NICHOLS

I was pleased with the quotation from Mr. Zander, page 204, April 1, as it was in the line I have been working for four years. The winter of 1909 I wintered a stand of bees in a hive with an opening in the bottom 6 inches by 12, covered with wire screen (as shown in the photograph taken the next spring); and as they wintered so nice-

ly, and did so well thereafter, I have used more of them each year since, until now I use no other; and the past winter I lost no bees, and they wintered on their summer stands with no other protection than a thin burlap on the top of the frame, and the super filled with crushed newspapers.

My hive, as you will see, has eight Langstroth frames, with a dead-air space on both sides, and half way down on the ends and rabbeted over the bottom at the sides. The entrance to the body is $\frac{3}{8}$ by 8 inches, with an entrance for the honey-flow, closed at other times, at the top of the frame $\frac{3}{8}$ inch by 2 inches. The super holds 35 sections, and is rabbeted over the body at the sides, and one super rabbets over the other. The top is 3 inches deep, with ventilators, and is rabbeted sides and ends to fit the super or the body. The roof is of $\frac{3}{8}$ -inch lumber covered with ducking, and painted. This roof is cool, never warps nor leaks, and my bees never hang out in summer, and seldom swarm.

TRAPPING HAWKS.

On page 242, under the head of "counting chickens before hatched," I notice the trouble with hawks. There is an old but successful way to trap a hawk. A hawk, before attempting a catch (as a rule), and always after an unsuccessful attempt to catch, seeks a point of observation. A very attractive one is a post in the fence higher than the others, or, better still, a single post in an open field a little distance from the fowl. We use a post as high as we can reach the top while standing on the ground,

and set a small steel trap on the post with a chain long enough so that it will staple to the post below the center so that, when the hawk alights in the trap, he will reach the ground and not tear loose from the trap, if he is caught by only one toe, which is often the case. The hawk, while shy of a gun, and wise in some things, looks not to his feet, and a trap set on a post needs no covering and no bait. The only objection is that we sometimes catch a useful bird that should not be caught; but we excuse ourselves by saying that one hawk in his lifetime will catch many such birds, and chicks and fowls that should not be caught. Dayton, Ohio.

TO PREVENT ROBBING WHEN FEEDING

BY DR. C. C. MILLER

A Virginia correspondent has trouble with robbing, and asks advice. He started feeding with the Boardman feeder, and when robbing began he stopped it by putting wet hay over the entrance. "Then," he says, "I ordered some division-board feeders and tried them, and every time I feed them they seem to go crazy and want to rob, and the combs melted down in one of my hives, and they got hold of some of the honey and started to rob worse than ever. I tried putting hay over the entrance, but it didn't do any good. Then I tried putting them in the cellar, and that didn't do any good. Then I piled hay all round the hives, and kept it wet for a good while, and they robbed through the hay. The strongest colonies make no attempt at defense at all, but the weaker ones will catch a robber every now and then, and give him a little roll. This is my first year at bee-keeping. I have eight colonies, and would like to save them if I can. How can I feed without starting robbing?"

That's quite a graphic account of a bad case of robbing, and will appeal to many an old beekeeper who has been through the mill himself. Only it's out of the ordinary that the weaker colonies make more attempt at defense than the stronger ones.

"An ounce of prevention is worth more than a pound of cure" is a proverb that applies especially to a case of robbing. Bees have no morals to speak of, and every bee is a potential robber. Most of them never find out that they *can* rob; but let a bee once get into its little noddle the knowledge that there is such a thing as getting in another hive stores piled up ready to hand, and it will risk—yes, and lose—its life in the nefarious business of robbing—nefari-

ous from the standpoint of the beekeeper, although not from that of the bee.

It's too late now to say just what should have been done, but it may do some good for the future, although one can only guess at some of the things you did or did not do. It would have been a little safer if you had used a Miller feeder. Being on top it does not present so strong a temptation to robbers as a feeder at the entrance or in the brood-chamber. Besides, it allows you to feed up more rapidly for winter.

It is safer to feed in the evening, after bees have stopped flying. By the time bees fly next morning the excitement will have died down, there will be less to attract robbers, and the bees will be in better condition to defend themselves; for when feed is first given to bees, they become excited over it, and seem to feel—at least sometimes—that when sweets are so very abundant there's no use to be mean about it, and so they allow free entrance to outsiders.

The wet-hay business is usually quite effective if begun early enough and the hay made wet enough. Possibly you failed on the latter point.

Putting the attacked bees in the cellar may do little or much good, according to management. If you merely took the bees into the cellar and then took them back again after a day or more, the gain is very doubtful. For when the robbers find the hive missing, they think they've made some mistake as to the location of their prey, and pounce upon one or other of the neighboring hives, merely transferring their activities there. Even if they should be driven out of these, when the cellared hive is returned to its place the change is quickly noticed by the robbers, and they renew the attack with vigor. So you must try to fool the bees. When you put the hives into the cellar, don't leave the stand vacant, but set on it another hive just like the removed hive in appearance, and in this hive let there be one or more empty combs, or combs with a very little honey. Then, instead of pouncing upon neighboring colonies, the robbers will continue their attention to this substitute hive; and after having cleaned the little honey there, if you have left any, they will become convinced there is no more booty to be had there, and will leave the hive. After they have given up their visits to the hive entirely, you may then return the colony from the cellar, in the evening, hoping that the robbers will not discover that the empty one is not still there. It may do some good to paint about the entrance with carbolie acid. Indeed, the carbolie acid alone will be a sufficient protection against robbing if it has not proceeded too far.

G. Frank Pease, of Marshall, Mich., with a load of honey, vegetables, etc., to take to the fair.

It is pretty generally agreed that it is well to make the entrance pretty small when robbing threatens or occurs, thus making it easier for the guards to protect it.

You have probably desisted from feeding now, for a time, and that is wise. When you begin again, if you have no Miller feeders you might use the crock-and-plate plan given in the book "Forty Years among the Bees" that you have. If there is danger of the weaker colonies being robbed when being fed, you could feed to the strong ones enough to have them fill some extra combs, and then give these combs to the weaker colonies.

Marengo, Ill.

MOVING AN EXHIBIT 50 MILES TO A FAIR BY AUTOMOBILE

BY G. FRANK PEASE

I am sending some pictures showing a load for the Kalamazoo fair. The load consisted of 800 lbs. of honey and bees, grain, vegetables, and fruit—about 1600 lbs. in all. The load was taken fifty miles and back. There was a heavy rain the night before I went, and the road was full of

A truck load in a touring car.

chuck holes; but I made the trip both ways without accident.

Fig. 3 shows a part of the load as it was in the exhibit, on which I won all firsts.

My car is a Reo the Fifth. I have run it over 2300 miles, and it never has been out of commission except to change tires from puncture several times, which takes from ten to twenty minutes.

Marshall, Mich.

BEE PARALYSIS OR POISONING?

Heavy Losses in a California Apiary from a Peculiar Malady

BY S. A. NIVER

Aug. 1, p. 547, under the heading "A Peculiar Malady or Disease," Mr. S. Fred Webber, of Colorado Springs, Col., writes a description of a condition in his apiary that makes me sit up and take notice. In a footnote the editor asks for explanations. I rise to remark, "Here too."

We have had two seasons' experience with something of that character, and it is a serious affair in this locality. From all indications and circumstances we had about concluded to lay it at the door of some local poison, and had pitched upon the buckeye as the disturbing cause. A hot wave blasted the bloom about that time, and bees were found dead, clinging to the blossoms as they sometimes are upon milkweed.

That was last season—1912. It killed over half of our bees, and was particularly fatal to young queens. We lost over 400.

This season (1913) has been another dry one, and we were on the watch for trouble, which came without any blasted buckeye, or at any rate came before that bloom showed any signs of being hurt by heat or any thing else; so our conclusions of last year seemed to need revising. Besides, a new symptom appeared, or was unnoticed last year. The young bees hatched prematurely, and without wings. They would dig out of the cells in a natural manner—little white fuzzy things, get one sip of honey, and make for the boneyard.

The old bees would come out of the hive at any time of day, keel over on their backs, claw frantically at their tongues, and keep pulling them out in an astonishing way until one would wonder where they concealed such a long big curved spike before the trouble commenced. That tongue was half as long as the bee; but, once clawed out, the bees were unable to get it back again, and died. Some colonies and some yards were worse than others.

The exhibit of G. Frank Pease as it appeared at the Kalamazoo fair.

I sent some of the specimens to Dr. Phillips, who replied, "No bacteria; know nothing about it," or words to that effect.

Now, Mr. Editor, if it was poisonous honey that killed the bees, old or young, worker or queen, what ailed the youngsters, sealed in their cells, before the poison showed up? Why their winglessness or "this thusness," as Artemus Ward used to put it?

There was no particular odor noticed until the dead bees began to decay; and as the malady subsided in about a month we concluded to say nothing about it, hoping it would prove only local, and due to the drouth, which would not occur next year when the big rain came. (Those big rains are all next year here in California, you know.)

Then here comes in that Mr. Webber, from Colorado, with his experience along the same line, and away goes our theory of the trouble being local and temporary.

Brother Webber, is there any buckeye, blasted or otherwise, in your locality?

Now turn over the page and read what C. W. Arnett says, p. 548, about losing colony odor, due (I guess) to Himalaya blackberry bloom. It is the same here, with not a blackberry; but the results! When all bees have the same colony odor, and no guard bee knows friend from foe, absolutely refusing to put up a scrap to defend stores, it puts things "on the blink." It becomes a go-as-you-please race, when bees rob indiscriminately, regardless of "race, color, or previous condition of servitude." In one instance some goldens were lugging

the honey from two hives of hybrids, and the gray Carniolans taking it from the goldens. A robber seemed just as welcome as the rightful inhabitant; and a colony robbed out completely would show up strong in bees, with a good queen and nice brood, but not a drop of honey.

This state of affairs has kept us on the jump, night and day, for a month; and the description of the schemes we have tried would be too long for GLEANINGS, so I will simmer down to the finale, which was to scatter them out over 25 miles of territory, and keep moving the robbers and feeding the destitute. My partner reports a few cases where guards are putting up a fight, so there may come a let-up eventually.

What do you think of bees, shut up tightly in their hives, passing stores through the ventilator wire cloth to robbers on the outside? Our loss to date is just about 50 per cent from malady and robbing.

Jamesburg, Cal., Aug. 25.

[We are at a loss to explain what may be the cause of this peculiar malady. We might suggest poison of some sort as being responsible; but that hardly seems tenable in view of all the facts presented. No particular source of honey can be ascribed to it. We shall be glad to hear from more of our subscribers who may have observed something similar in their respective localities. If it is a new disease or malady, and if it be seriously contagious, we ought to take a stitch in time. We feel satisfied that Dr. Phillips, at the Bureau of Entomology, will

be glad to do any thing he can, and we suggest that all specimens of diseased bees be sent to Dr. E. F. Phillips, Bureau of Entomology, Washington, with a detailed description of all the symptoms.—Ed.]

LOCALITY AND HIVES

The Danzenbaker a High-pressure Hive

BY W. O. ROUDABUSH

I read with much interest the article on page 699, Nov. 1, 1912, by C. A. Stevens, on "How Locality Affects the Question of the Choice of Hives." I don't know that I would have had more than passing interest in this communication if his experience had not been given with Danzenbaker hives. In my imagination I can see Mr. Stevens with a woe-begone expression on his face when he lost virtually all his bees the first winter. It is no small wonder to me that he ever put more bees in Danzenbaker hives; but he seems to be a "sticker;" and as stickers are the only ones who will win out with any hive, I take off my hat to Mr. Stevens.

I have used the Danzenbaker hives for about ten years. Prior to this I kept bees in the old beveled-edge Simplicity hives. Then the ten-frame dovetailed, and later the eight-frame dovetailed hives; and from what experience I have had with the Danzenbaker hives I would say that location may have something to do with the question of success; but management has a great deal more. The Danzenbaker hive is adapted ideally, I think, to what I would term high-pressure beekeeping. High pressure in bee culture, as in any other vocation or business, calls for constant attention to details. With a hive the brood-frames of which are only $7\frac{1}{2}$ inches deep, and a good prolific queen to keep the brood-chamber full of brood during the honey-flow, one has the best combination I know of for the production of fancy comb honey.

Comb-honey production, after all, is nothing more nor less than crowding the bees to store this honey where we want it—in the supers. With the Danzenbaker hives I have had as many as eight frames of brood solid from top to bottom, clear out to the end-bars—a thing I never could accomplish with any other hive except once in a while with an extra good queen—say one in a hundred; and at the end of the honey-flow, after removing the supers, I have had colonies that had given me over 100 lbs. of strictly fancy honey that would die of starvation in one week on what stores were left in the brood-chamber if left to their own

devices. This is why I call it high-pressure beekeeping.

In the hands of an industrious, experienced beekeeper, one who has a system and follows this system to the letter, never waiting to do to-morrow what ought to be done to-day, and who may wish to work his bees for all they will do, I don't think a better hive than the Danzenbaker can be found. On the other hand, with the man with no system, who puts colonies out to "go it," is usually rewarded by seeing them go away and never return.

With plenty of stores of sugar syrup which costs me about four cents per pound, and which I trade to the bees for 15-cent honey, I never had any trouble in wintering my bees in Danzenbaker hives on summer stands; and when it comes to building up in the spring, I think this hive is far ahead of any other I have ever used.

I have seen some writers in the bee-journals complaining of the difficulty they experienced in handling the closed-end frames of the Danzenbaker. This frame-handling also comes under the head of "Know how." Several years ago I bought some queens of a neighbor who was kind enough to see that they were safely introduced. He is an experienced beeman, and no tenderfoot in the business, and after opening a hive and having several frames upset he looked at me and said, "If I had to keep bees in such hives I would lose my interest in the business." After showing him how the frames were handled he said nothing more to me about it. He came one day when I was away from home to see if the queens were laying, and told Mrs. R. he believed he could learn to like the hive very well. In August of that year I had ten new Danzenbaker hives set up that I had no immediate use for. My neighbor came to me and said if I would let him have those ten hives he would transfer some bees into them that were in hives that, through age, had given out. The next spring he transferred 60 colonies to Danzenbaker hives, and likes them better than the ones he previously used; so in this it is to understand first the hive. I can handle Danzenbaker frames faster than than I can handle the hanging frames, because I can handle them in twos, threes, and fours, and never kill more bees than with the open-end hanging frames.

After taking all the honey the bees have been able to make, if one will see that they are well supplied with stores for winter, and will understand that the object of the inventor was to use a frame so shallow that it would force the honey into the supers, and learn to use the closed-end frames properly, I consider the Danzenbaker hive

the best one for fancy comb honey in use to-day; but to attain success one must be always on his job.

As to the claim made by some that bees in Danzenbaker hives will swarm more than in some other hives, I have found by experience that, when the conditions are right for swarming, they will swarm from any hive unless prevented from doing so by some interference from the beekeeper; but I see that they swarm only a little more from Danzenbaker hives than other hives. I confess that, as a general rule, crowding will produce swarming, and the smaller the hive the more crowding can be done, and the more the bees feel the need of more room.

Hagerstown, Md.

AN OUTDOOR COLONY

BY C. E. BARTHOLOMEW

The accompanying picture shows a swarm of bees that chose the under side of a fallen elm tree upon which to establish their home. This was a large colony, and when found had built out nearly as much comb as would be required in the brood-chamber of an eight-frame hive. The most peculiar thing about this colony was that the brood (and there was a large amount of it at the time the colony was taken) was nearly all on the outside of the outside combs. There

A colony that built combs out of doors. Nearly all of the brood was in the outside combs, the honey being in the inside.

was several pounds of honey stored in the inner combs. This colony was taken August 4, and has now settled down to work in a ten-frame hive. The photograph shows the side view of the combs as the bees clustered upon them. This is the third time I have observed comb-building in the open; but this is the first instance where they were caught while at work.

Ames, Iowa, Aug. 15.

A CAUTION AGAINST SOME METHODS OF DIRECT INTRODUCTION

BY J. C. MOSGROVE

Opinions on direct introduction vary among beekeepers as much as the temperaments of the different races vary among the bees. I am not picking for a scrap, but I am *not* in favor of using smoke when running in a queen, for this reason: If it is at a time when there is a dearth of honey the colony will be demoralized to such an extent that it falls an easy victim to robbers, or the smoke may cause the bees to fall upon the queen and kill her.

I am in favor of placing the queen close to the entrance and letting her slip quietly in without any commotion whatever. I practice this method, and I get very good results. But for beginners and all amateurs I would advise the use of a Miller cage. This cage is best, too, for introducing a queen from the mails.

In regard to odor I shall not argue that point; but this I will mention: Mr. Miller states that in an apiary of thirty odd colonies there were three distinct strains of Italians and one of blacks; and as the honey-flow was extremely light until the middle of July, an examination of the colonies showed very few bees in them that were not raised there. Directly following there was a heavy flow from caletbra, and within a week every colony had a considerable part of its population made up of all the different strains. He asks, "Had the bees' sense of smell gone wrong?" No, I don't think so, and odor had nothing to do with it either, because a bee coming from the fields heavily laden with honey or pollen, alighting in front of a hive other than its own, may crawl unmolested within. Why? Because a laden bee going into a strange hive is not looked upon by the inmates as a thief or an interloper, for it brings its burden to add to the store, and is not trying to pilfer the fruits of another's labor. On the other hand, just let an empty bee go buzzing around a strange hive. What is the result? In plain English, she is very promptly "kicked out."

As to closing the entrance of the hive and pounding on it with the fist, that may at times prove disastrous. I have resorted to this to cause the bees to fill themselves with honey before shaking into the grafting-box, and found the queen badly balled. This taught me a lesson. Now I always find the queen and set the frame she was on in a safe place to one side before pounding on the hive; then after shaking what bees I want I hang the frame back in the hive with safety, as the bees on the frame with the queen have not been unduly excited, and those in the hive have filled themselves with honey until they have become logy and have no fight left in them.

Medina, Ohio.

ROUTING OUT THE BUMBLEBEES

BY MRS. S. L. DORSETT

As I have not noticed in GLEANINGS any thing in reference to the bumble-bee I thought your readers might be interested in a bumble-bees' nest that was found on our premises last week, a photo of which I inclose herewith. These bumble-bees are the black-headed kind, the kind that sting so viciously. These bees had built 75 large cells and 25 smaller cells directly on a board shelf in a building in which grain and feed were kept, ingress and egress being made through a window. At first only one or two large bees were seen at a time, and nothing was thought of their presence except that they came a little too near sometimes when one went inside the building; but in the course of three weeks, as nearly as we can tell, these bees became so cross that it took a brave one to enter the building, for they would circle around one's head and throw off a rank odor, making it very plain that they were ready to fight to defend their young.

It became necessary to get rid of these troublesome intruders, hence a well-filled smoker was lighted, and two people, well protected with gloves and veils, entered the building. After filling the air with smoke, as much as one could stand to remain inside the building and work, the material on the shelf was cautiously removed, and there, directly on the bare boards, were a hundred beautiful cells. Over the top of these cells was a layer of bits of rags and waste, just such as a mouse would use for a nest, but it was woven together much better than a mouse-nest. It was more as a bird would build a nest, only it was put over the cells covering them completely except one opening just large enough for one bee to pass in

A bumble-bees' nest built inside a coil of rope.

and out. The whole nest was about as large around as a table saucer, and four inches high. Twenty of the cells had hatched, and in their cells was found some rank-smelling honey. The newly hatched bees were in the vacant space up over the hatching cells. The nest as shown was built in the center of a coil of rope, and in shape it very much resembled the old-fashioned straw hive.

West Point Pleasant, N. J.

CARNIOLANS AND THEIR CROSSES

BY SAMUEL SIMMINS

In a recent issue information is asked for regarding Carniolans superseding queens, swarming, etc.

Ever since Mr. Benton first offered these queens and bees I have continued to import both queens and stocks down to the present time from the native breeders. I have at times imported original stocks in the original long flat hives in which the combs travel well, without breaking, as a rule. My last consignment of this kind came to hand in early June of 1911. It was chilly for the time of the year, and the bees were as silent as death upon arrival, being all but starved through the stores not holding out.

But these Carniolans, while naturally quiet under confinement, always travel well, for the reason that our Carniolan friends have learned that young bees travel safely (with combs) almost any distance if they have just enough food, which is not always the case. The old bees are disposed of by moving the hives to a fresh stand a few

days before packing for export. Thus one has a good foundation of all young bees to start on when they are transferred to frame hives.

As usual the stocks referred to were transferred by first removing the top board, to which the combs are attached. These, with the mass of bees covering them, are then turned over, when, beginning with a side comb, each is gently sliced off, and the bees shaken into the permanent hive prepared for them close by. Very little smoke is required; and as a rule one may thus transfer ten or a dozen lots without getting a single sting.

With bees imported early in the season the queens are of the previous year; but I do not find these bees any more given to swarming than imported Italians, nor are they likely to supersede the queens more than such Italians are known to do.

During 1911 we had a particularly long fine period after a cool spring, and the several imported stocks I retained stood the whole summer without swarming; and even though I cut out no queen-cells they became very populous, and none of the queens were superseded.

But now I must mention a strange peculiarity found with these bees. They go and come rapidly in large numbers all day long, but the work done is not commensurate with their apparent activity, and they do not store as heavily as my line-bred Italians, which come home more slowly and drop heavily on the alighting-board with their bodies distended with the weight of honey carried. Pure Carniolans do not carry such loads, and, like pure Cyprians or Syrians, appear *unable* to load up so heavily.

As each of these three races is invaluable for crossing, producing bees that will store heavily in some localities where imported Italians are quite useless, they should not be hastily condemned because of their apparent inferiority as pure races.

Carniolans crossed with our natives produce workers that yield large crops of honey; but the temper of the bees is somewhat troublesome. They are, however, not so unmanageable as Cyprians or Syrians when crossed with blacks.

Carniolans mated to imported Italian drones are of little value. Such Italians crossed with Carniolan drones are more useful, and the workers are superior to either race pure.

Cyprian and Syrian queens mated to Carniolan drones throw workers that are good-tempered and very strong workers, but are even better when crossed with a good strain of Italians.

It may be taken for granted that Cyprians mated to a suitable strain of Italians will produce bees of more general utility than any other strain of Carniolans or Italians, pure or hybridized. Syrians do not lose their bad temper through several crosses; but it is a strange fact that Cyprians of the first cross to an Italian drone of a good-tempered strain will show workers which are more gentle than any pure Carniolans or Italians known. I can vouch for this from many years' experience in crossing these bees; and I am not in the least surprised that Mr. Burrows has recently been under the impression he has found a stingless bee. Personally I do not remember ever being stung by any bee of the most populous hive containing this Cyprian cross with Italians, whether in the warm or cool season; and as to wintering, they are at all times bright, slim, and active, rarely or never showing that somewhat bloated appearance found with some Italians and their hybrids when long confined.

For comb-honey production it would be better to cross Cyprians with Carniolan drones, but for heavier results with good Italian drones.

With over thirty years' experience with Cyprian bees and their crosses I have so far found none with disease of any kind. Italians are more immune than natives to both brood diseases and paralysis; and somewhere about the year 1906 in articles of mine published in GLEANINGS I showed how Italians were able to overcome brood diseases better than blacks. I also included Carniolans as being able to keep such diseases at bay.

Mr. Frank Benton declared that no foul brood was known in the locality from which Carniolans are imported; and in your journal for April 1, 1911, p. 203, you will find Carniolans placed ahead of Italians; as Mr. J. T. Dunn says, "Carniolans would withstand this disease when Italians in the same apiary were infected and reinfected." Possibly these Italians may have been somewhat inbred, as usually they do not readily give way to disease.

Heathfield, Sussex, Eng., Dec. 26.

MORE COMB HONEY AND LESS OF EXTRACTED

Importance of Proper Packing of Comb Honey; Conditions in the West

BY M. A. GILL

You have been advocating in time past the production of comb instead of so much extracted honey. Mr. Root, you stand in a position to wield a great influence; and you,

together with that prince of good fellows, and a very dear friend of mine, W. Z. Hutchinson, have in the past rather favored the production of extracted honey. I know nothing of the conditions in the East; but I do not think there has been the deflection from the one branch of the business to the other that you think. Take California, Colorado, Idaho, and Utah. Outside of California, where there has been a little falling off in the production of comb honey in the past few years, I think there has been a gain in the other States in the tendency to raise comb honey; and the fact that less honey has gone forward is because of the poor seasons rather than a changing to extracted honey.

You strike the keynote when you speak of the miserable handling of a part of the comb honey offered to the market. Now, if a campaign is to be started urging the production of more comb honey, let's first start a school urging the placing of a better grade on the market.

It matters not how slipshod the methods are that produce a can of extracted honey. If it is ripened, settled, or properly strained, it's all right for the market; and any one who can turn a grindstone can produce extracted honey, whether at a profit or not. But the man who is to place a case of comb honey on the market must cater to the appetite of the eye, for he is dealing with an epicure—one who is buying a luxury; and he must strive to excel by, first, honesty of weight; second, quality; third, neatness of appearance; and he who meets the above requirements must be a man of pride for and taste in his work. If the advice to produce more comb honey were taken in many cases, where the extracted apiaries have been run with hired help, schooled only in the rough methods by which a crop of extracted honey is obtained, in many cases the product would be no better (perhaps worse) than now. Then let them go on and produce the excess (if there is to be any) in the extracted form, for it is much more capable of being worked off than an excess crop of comb honey, whether in good or bad shape; for we must never lose sight of the fact that comb honey is a luxury, and luxuries must be neat and attractive to sell well.

Utah is just as good a honey country, and even better bee country, than Colorado; but its beemen sadly need the schooling that the Colorado comb-honey men have had for the past fifteen years. Utah's comb-honey men need to get together and school themselves, using the motto "The best is none too good," which will remove the low price and bad name that now hangs over us, for no better

can be produced anywhere; and I certainly felt flattered this fall when I read in a paper an account of a carload of comb honey that I had sold to an eastern buyer. He said that he had bought from me the best-handled car of honey he had bought in an experience of twenty years.

I am not one of those who think that more bees can be handled for extracted than comb honey, after having had nearly twenty years' experience with each; neither do I think that the production of extracted is more profitable when we take a term of years and take into consideration the condition of the capital stock.

If you would travel over the country and see the outfits that some people are using, and see the "fool supers" in which it is impossible to produce a first quality, you would be surprised. This, of course, is on account of the "penny wise and pound foolish" plan of saving a nickel rather than use standard supplies.

In conclusion, I will say, as one who has been in the comb-honey business exclusively for twenty years, waiting for the time when quality would be appreciated, that, if a crusade is to be started inducing more people to raise comb honey, we should use my old class motto at school: "Not how much, but how well."

Hyrum, Utah.

QUEENS INJURED BY BEING SENT THROUGH THE MAILS

Number of Queens Shipped in a Nucleus

BY LOUIS MACEY

While the mailing-cages in use at the present time are cheap, simple, and convenient, and many queens "go through safely" in them, usually arriving in apparently good condition, it is universally conceded that a queen which is sent in this way through the mails very seldom arrives in normal condition. Conditions are not most favorable, therefore, to her passing muster with the strange bees and with her new owner. Never in all her life is a queen subject to such critical inspection as when introduced. The biped inspector has only two eyes, and a much less critical "smelling apparatus;" but his criticisms do not end with the first day, nor with the first week. Even after two or three weeks of prying into her work he is still in good position to "make a kick."

Everybody admits that the queen is strange to the bees and in an abnormal condition as to nerves, because she is so tired and frightened that she is in poor condition to maintain that queenly dignity so neces-

sary to the morals of the colony. But it must also be admitted that such a queen taken in the flush of her egg-laying, and confined with only five or six of her subjects, with no chance to lay, and subject to "rough handling and to being chilled in the mails," is in very poor condition all around to resume her normal rate of egg-laying so as to satisfy her most critical judge—the man who paid for her, and naturally expects something. Some queens die in transit. Others, while they pull through alive and in apparently good condition, have been rendered practically worthless by the hardships of the trip. Numerous instances have been cited of good queens starting, which, after arrival, became drone-layers.

Would it be going too far to say that few queens going 300 miles or more ever regain their normal usefulness? If they are good ones, and regain within 10 or even 20 per cent of their normal efficiency, it might not be noticed, and they would still be classed as good. Nevertheless, the loss would be there; and would be felt by the breeder as well as the buyer. Northern beemen recognize the desirability of getting early queens from the South. Southern queen-breeders would like to sell more queens, so it seems to me that one of the biggest problems before us is to minimize the chances of injury, or, in other words, to provide such conditions as will keep the queen as nearly normal as possible while in transit. Shipping in nuclei does this; but the expense is too great for one queen.

I have an idea. It may be old, and it may have been tried before; but in the five years I have been reading bee lore, I have never seen any mention of my plan. Breeders advise shipping \$5.00 and \$10.00 queens in nuclei, but say nothing about shipping five or ten \$1.00 queens in a nucleus. Why not? Beekeepers can not afford the transportation charges on a nucleus with one \$1.00 or even \$2.00 queen; but they could if it contained ten or twenty queens, all safely protected from rough handling and chilling by the same bunch of bees. Do not call me a fool yet. Of course I don't mean to turn ten or twenty queens loose in a nucleus; but when breeders raise twenty or more queens to mating age in one frame, why should they not be able to ship the same number in a modification of the same frame with a warm living wall of bees on each side? With cages placed back to back, something like 50 could be placed in the middle frame of a nucleus; and if there would be danger of the outside bees pulling the queen's legs off, use a finer-meshed screen.

Suppose I want 16 queens next spring, and I want them to come through from

Texas, and I want them to come through not only alive but in a condition as nearly normal as possible. What is to prevent the breeder from taking some unfinished sections, putting candy in one corner, a sponge filled with water in another, tacking wire gauze on each side, pouring in a handful of bees and a queen and then fitting the whole 16 sections of baby nuclei in a special frame, and putting this between two frames of brood and bees in a nucleus box? While he was about it he could partition the box with screen each side of the middle frame, and put a queen with the bees in the two outside frames. That would make 18 queens, and each one protected from rough handling and chilling, and with some natural comb to crawl over, cling to, and perhaps lay in. Why not?

Still another: While E. R. is experimenting with pound and half-pound packages of bees, why not try sending a queen in with them? When one needs queens, a few pounds of bees would never come amiss. If a single package will go safely, wouldn't six, eight, or a dozen—isolated or not from one another with cardboard if necessary—hold heat and go together in one package all the better?

North Platte, Neb.

A HIVE HAVING AN OPEN BACK THROUGH WHICH TO DRAW THE FRAMES

BY GEORGE T. WHITTEN

The pictures show my new general-purpose hive, before and after the bees were put in. It is 20 inches long, 13½ wide, and 12 high. It takes the regular eight-frame super or hive-body on top. The frames work on the same principle as those in the observatory hive, and are shorter and higher

George T. Whitten's hive made on the Prokopovitch principle of removing combs through an open back instead of at the top.

Some of the combs pulled out to show ease of examination when supers are on top.

than the Hoffman frames to fit this hive. The front bars of the frames are one inch wide to prevent the bees from building comb on the sides or between them. The top and bottom of the hive are 20 inches long, and sides are $\frac{7}{8}$ shorter. The back or door is of double boards. The inside one shuts inside the hive-body, has tins around the edge to prevent the bees getting at the boards to stick them together, and to force them away when closing the hive. This works perfectly, and does not crush a single bee. To look them over, the supers do not have to be touched. This does not disturb the bees at all in their work. I can examine them in a few minutes, and it is a pleasure to do so.

Hartford, Ct.

[We will explain that Professor Whitten, of the Handicraft Schools, Hartford, Ct., is the inventor of an observatory hive which he exhibited at the convention held at Amherst, Mass., early last summer. We hope to illustrate this soon in our columns. He has also devised a hive embodying the same principle for ordinary hives. The accompanying illustration will show the scheme. The top-bars and bottom-bars of the frames slide in metal channels in such a way that there is no chance for the bees to propolize. While it is possible for one to examine any comb in the hive without lifting off the supers, the arrangement, we fear, will not

prove to be very satisfactory as a permanent working hive run for regular honey production. This same principle was used by some of the early inventors, among them being the celebrated Prokopovitsch, in 1830. Baron Berlepsche, of Austria, used a hive something on the same principle, with this difference: The frames were moved from the end or side of the hive transversely. The principle shown in these illustrations has been used to a greater or less extent in Europe ever since. But it has never been used to a great extent by large commercial honey-producers. The main objection is that frames secured in a hive as here shown are all at fixed distances apart with no opportunity for spacing further apart. There is quite a tendency for bees to attach brace-combs during a heavy honey-flow, hence the combs will be bulged in a way that would make removal difficult and slow. This will result in killing bees by rolling them over and over as the frames are drawn out. With ordinary hives opening from the top with self-spacing frames, the removal of a division-board or a single frame leaves room for spacing the other combs further apart, so one can be easily lifted out.

Of course, there is the advantage that the brood-nest can be examined without removing the super. But in practical bee culture there is seldom any occasion for this.—Ed.]

HOW TO TAKE AN INVENTORY OF A BEE-YARD

Sending Honey by Parcel Post Not Satisfactory

BY H. G. BRANT

In taking inventory at the close of the season, what value should be placed on equipment in use—for instance, hives that are as good as new to the beekeeper, but are one or more seasons old?

What value should be placed on drawn comb, full colonies, etc.?

What form should the inventory take? So many bottom-boards, so many bodies, so many covers, so many frames, etc., at so much?

That the time is not yet ripe to ship honey through the mail by parcel post was well illustrated one day last week at the postoffice in this city where I am employed. A sack was dispatched at Tomah, Wis., containing a ten-pound friction-top pail of extracted honey. Heavy sacks of mail piled on the one in question caused the cover to spring, and the contents smeared all over the rest of the mail in the sack. The package has not been perfected which will permit the shipment of honey by parcel post. Also, except in the local, first, and second zones, the rates are too high to permit any profit if the honey is to be shipped in a satisfactory container. I handle only parcel post for eight hours every day, and see a great many queer packages; but the one last week is the first honey I have seen. Eggs in considerable quantities are received and shipped. These, however, are packed in six-slatted carriers with a handle like a pail. As a writer in a recent number of *GLEANINGS* said, "A basket or pail with a handle on that can not be thrown or laid on the side is best."

The fall flow this year was very poor, a dry spell at the close of the clover flow preventing secretion of nectar. The white clover was the best for several years. My colonies averaged 100 to 110 lbs., and one gave 48 lbs. in nine combs with wide spacing. This is the first season I have tried it; but all supers with nine combs spaced wide gave more honey than those with ten combs.

St. Paul, Minn.

[In order to get at the valuation of second-hand hives and parts of the same, it will be proper to start off with the cost of each item nailed and painted, and laid down at the apiary. The usual rule is to charge off 10 per cent a year on machinery and tools or appliances. It is generally considered that a tool, machine, or appliance will be worn out or become out of date in ten years. In figuring this we charge 10 per cent on

the first cost of the article every year. To be specific we will suppose that the hives in the yard have been used five years. Ordinarily we would write off 50 per cent; but as lumber has advanced in value so sharply during the past few years, a second-hand hive is beginning to be worth almost as much as a new one, if not quite. See what P. C. Chadwick says elsewhere in this issue, page 750. If a hive has been painted regularly, say once in two or three years, and on regular hive-stands so the bottom does not come in contact with the earth, it ought to be worth as much as a new one. As to the cost of the bees themselves, that will depend on their market value in the locality, whether they are pure Italian stock, pure Carniolan, or whether a mixture of several races.

In some parts of the country bees are in great demand, from the fact that a single colony will very frequently save its first cost in one season, and sometimes considerably more. In other localities, especially after a series of poor years, a colony of bees will bring only a nominal price.

There is another factor that must be considered in the cost of a colony, and that is the queen. A queen whose bees far excel any other bees in the yard in the production of honey may be worth far more than the average run of queens. It is not an uncommon occurrence for a beekeeper to say he would not take \$25.00 for a certain queen. A colony with such a queen would be obviously worth \$25.00 plus the value of the hive and bees. A colony with *daughters* from this queen will be worth more than colonies having ordinary queens.

Generally speaking, a colony of pure Italians in a new hive, of a good strain, will be worth anywhere from \$7.00 to \$10.00 in the early part of the season. After the crop has been secured, there will be a temporary depreciation of probably 50 per cent for the reason that their owner must feed them and assume the risk of wintering.

Another important factor in the valuation of a colony is the kind of frame and condition of the combs. If they are only one or two years old, well wired, in well-made factory frames, they are worth very much more than crooked combs in home-made frames. Good drawn combs one or two years old are worth anywhere from two to three times as much as new wired frames of foundation. The latter in a honey-flow do not begin to compare in value with drawn combs. While foundation can be drawn in from 24 to 48 hours, this drawing-out necessarily absorbs a large force of bees from the field, and of course this would mean a loss of honey. And this is not all. The foundation may discourage the bees

and cause them to swarm. This is the principal reason why producers of comb honey have more trouble from swarming than those who produce extracted honey. For that reason we place a higher value on drawn combs than is ordinarily set. They are in fact the best kind of property that the producer of extracted honey can own. If filled with pollen for early spring breeding they are worth as much as the same combs filled with honey or sugar syrup.

We do not think it would be necessary to apply the rule of 10 per cent depreciation on drawn combs; for if properly taken care of, and kept away from the moth miller, they ought to be good for 25 years. The depreciation, then, should not be more than 5 per cent a year; but in the hands of a careless beekeeper the depreciation charge might be nearer 25 or 50 per cent a year.

Your experience in sending honey by parcel post is in line with other reports we have received.—ED.]

GREASY WASTE AS A SMOKER FUEL

Auto Trucks for Out-apiaries

BY R. V. COX

I notice there is some discussion about cotton waste. I never had a good chance to get this fuel till this year. Perhaps my bees had got used to rotten wood, and did not like the smell of the new smoke. This is a poor reason; but my bees certainly gave me all that was coming to me several times till I changed to the old fuel, and then they let go and were decent.

I remember your speaking of the automobile truck in GLEANINGS as a light truck, 1000 lbs., I think. Do you draw the full supers of honey home on it and the empty ones back? If so, do you not have to make several trips a day with it?

I have had several poor(?) years here, and think of trying outyards and a truck. Sloansville, N. Y.

[We do not understand why your greasy waste should not give you just as effective service as that you could secure from rotten wood, corncobs, or any other material. In using fuel it is important to get it well ignited. We never saw a colony yet that we could not subdue with greasy waste. If the bellows is worked vigorously a few times, the smoke will roll out in a dense volume of a bluish-white color.

We have used an automobile truck for our out-apiary work during all the past season with great satisfaction. Our truck is capable of carrying 1200 lbs. at a load, at an average speed of fifteen to eighteen miles an hour, and is capable of a maximum of 22

miles an hour. It will do the work of two or three teams at less cost, and at the same time enable one to have his outyards placed far enough apart so the bees in their flight do not overlap each other. Some of our yards are over ten miles from the home yard; and yet at this distance we are rarely more than forty minutes on the road, even when loaded down.

We have had no engine trouble—in fact, no trouble of any sort. The truck has a friction drive capable of all speeds. We are thoroughly convinced that a truck with this kind of transmission is better for all kinds of roads, and certainly better for the average driver, than the sliding or planetary gear. Such gears are liable to be stripped, and, what is more, the sliding gears require a much greater degree of skill to operate. The friction drive on the other hand is very economical in that the wearing surfaces do not cost to exceed \$2.00 for renewal a season, and a broken sliding gear may cost anywhere from ten to one hundred dollars to replace. The machine we have driven with such satisfaction is the Commerce, manufactured at Detroit, and costing less than a thousand dollars, complete with top and storm aprons.

It has been our practice to carry full supers of filled combs from our extracting-yards to the home yard to extract, where we have our extracting-outfit, and then carry the empties back. As the truck can make quick and frequent trips, no single hive is deprived of its full quota of combs more than an hour or an hour and a half at a time. A large power extracting-outfit will just about keep up with the truck coming in with full combs, and returning with the empties. It goes clear into the apiaries, and up to the door of the extracting-house.

Again, an auto truck enables one to split his full number of colonies up into comparatively small apiaries. In this way overstocking is avoided. With a team of horses it is not practical to have a yard smaller than a hundred colonies nor further than two or three miles apart; but with a light automobile truck one can operate out-yards of thirty, forty, and even fifty colonies five and even ten miles apart. In a locality that is rather poor this is a great advantage. If a small beeyard can have all the nectar it can reach, the individual yield per colony will be relatively much larger.

We are well satisfied with our investment of the automobile truck; and we believe the day has already arrived when the beekeeper of 500 colonies will find it a saving over a team; and, if he owns one thousand or more colonies, an absolute necessity.—ED.]

Heads of Grain from Different Fields

I am like the busy little bee
That works with all its might
To gather honey every day
And eat it up at night.

Rev. Wallace.

Combs Melting Down on Hot Days; the Remedy

I have lost an average of two full honeycombs per colony, besides some half a dozen colonies outright. Our summers are made of a variation of hot and cool spells. The north wind will blow for several days, running the thermometer up, oftentimes, to 112 degrees or more. Then, as a rule, the cool south wind springs up, and continues blowing until it feels quite cool.

Some of my hives are under large oaks in the best of shade, and some out on a glaring hillside. Of course those in the hot sun suffered most from the heat. My theory is that ventilation over the tops of the frames would prevent this loss, whether a hive were in the sun or shade. I propose taking a comb-honey super and tacking screen over the top and bottom, also over an inch hole bored in one end of the super, then place it between the cover and hive with the hole toward the west, away from all prevailing winds. Would this be sufficient protection to hives out in the sun?

VENTILATED ESCAPE-BOARDS.

The new bee-escape board, described on page 577, looks more practical. I have given the Porter bee-escape boards up. In hot weather I feared to use them, and in cool weather they would not free the supers of bees in two or three days. I have seen a La Reese bee-escape board advertised. Are they good?

In an ordinary year my bees gather honey more or less from February to October. The winters are open and mild, giving the bees opportunity to fly out nearly every day. How many full combs should a colony have to winter on?

HOW MANY POUNDS OF EXTRACTED HONEY CAN ONE TAKE WITH A TWO-FRAME COWAN EXTRACTOR?

Can you tell how many pounds of honey a man can extract in a day with a Cowan two-frame extractor? I can average only 500 pounds a day. I am one beekeeper who greatly appreciates the A. I. Root Co., and consider the knowledge gleaned from the A B C and X Y Z and from GLEANINGS worth hundreds of dollars to me.

West Butte, Cal., Aug. 24. R. A. WILBER.

[The remedy for combs melting down is to place all hives that are out in the hot sun under some kind of shade. This may be done by the use of shade-boards, or, better, by placing the hives in the first place in the shade of a small tree that will protect them during the hottest hours of the day. Additional ventilation will doubtless be good also. The scheme you propose would give no more ventilation than would be secured through a one-inch auger-hole, because the cover will fit down over the wire cloth of the super. Some beekeepers use the plan of giving ventilation through the upper back end of the hive. This may be done by putting on a rim or super having two or more holes at the back end. These may or may not be covered with wire cloth. A strong colony will guard these holes the same as they would an entrance. Another scheme is to tilt the cover back a little—just enough to give ventilation at the front and back. We do not think you need to have any trouble from combs melting down if you put the hives in the shade and then give ventilation at the top and a large entrance at the bottom.]

One man working alone may be able to take as much as 1000 lbs. of extracted honey a day with a two-frame Cowan extractor providing all conditions are favorable; but as a rule the general average will not be much if any higher than you have been able

to secure. Of course, if one has a good helper he can more than double the output of one man. If the hives are quite a distance apart, frames stuck together with brace-combs, and badly glued to the hive in addition, the progress of the work will be much slower. If, on the other hand, the frames are modern, spaced 1½ from center to center, without brace-combs, hives close together, and near the extracting-house, one can, of course, take more honey in a given time. If he follows the practice of some, and extracts before the combs are entirely capped, or if he goes still further and extracts before they are capped at all, he can take, of course, more gallons of honey; but it may, and probably will, be honey of a very poor quality.—Ed.]

Introducing; a Modification of the Caging Plan

I catch the undesirable queen, mash her head (don't quite kill her), run in the queen that is to take her place with her at once, with no workers. I push enough queen candy in the hole to last about six or eight hours; place the cage right in over the frames, and the job is done. I had not a bit of trouble with this method when robbing was rampant. Let us compare the old with this new plan a little. By the old plan of having the bees without a queen for a day or two, queen-cells are invariably started; and when the queen is liberated from the cage she is likely to be balled and sometimes killed in favor of the cells; and about the only way to ward off this trouble is to cut out the queen-cells, which is almost impracticable. By this new plan we have conditions about as close to nature as we can get them. First, we have the odor of the undesirable queen to start with, and the bees don't seem to realize that any but their queen is in the cage, and therefore they rarely if ever ball the cage; second, when the queen is liberated she must have acquired the odor of the dead queen. By this method the bees are without a queen only about half a day, which is a big thing in the way of eggs and population.

Swainsboro, Ga.

S. CHEATHAM.

Does a Queen Lay in a Queen-cell?

The question was up in last GLEANINGS about a queen laying in a queen-cell. I have sometimes heard it questioned whether she actually lays in queen-cells or the workers place the eggs there. This recalls an experience I had last summer. In looking through brood-chambers I found a queen caught head first in a queen-cell, or, rather, a queen-cell cup. The evidence was strong to me that she had just stuck her head in there to see if every thing was all right before depositing the egg, and by some means had got caught. When I liberated her she was uninjured, and went on about her work.

Guelph, Can., Feb. 25.

MORLEY PETTIT.

The Use and Abuse of a Smoker

Kindly advise me how I must smoke the bees. Must I give one, two, three, or a dozen puffs into the hive? Must I blow the smoke into the entrance before I open the cover, blowing the smoke up into the frames, or must I remove the cover and blow the smoke down? (This latter way seems useless to me, because smoke won't go down.) Then after I smoke them, how long should I wait before taking off the cover? Should I handle them at morning, noon, or night, I mean, to find the queen? Then how shall I know if she is young and fertile or old and sterile?

G. D. CAMPBELL.

Weymouth, Nova Scotia, Can., Sept. 3.

[It is hard to give any general rule applying to the use of a smoker, for most beekeepers have their own particular ideas on the subject. In general we

may say that, in our opinion, most beekeepers use too much smoke. The point is, to use smoke to prevent the bees from "boiling up" or making an attack. An experienced beekeeper knows just when to use a little smoke to avoid a general uprising. It is far better to prevent than to try to stop a vicious onslaught by the use of large volumes of smoke afterward.

It depends somewhat upon the bees in question; but when you go to a hive to open it, it is safe, as a rule, to blow a very little smoke in at the entrance, just enough to overcome the tendency on the part of the guard bees to rush out. Then, being as careful as possible, pry up the cover just a crack, or pull the quilt away slightly from one corner, as the case may be, blowing in a little smoke at the same time. Theoretically, smoke will not go down; but in actual practice it can be blown down between the combs. However, a great amount of smoking should be avoided, as it is usually not necessary. As soon as the bees have gone down somewhat from the top-bars, you can proceed to loosen the frames and take them out. Be sure to have the smoker handy, where it can be used at an instant's notice, at the first indication that the bees are resenting the intrusion.

The best time to hunt for queens is during mid-day, say from ten o'clock until two, or on warm days from nine until three. Many of the bees will be out of the hives then if a honey-flow is on, and it is not so difficult to find the queen. Avoid opening hives early in the morning or late in the evening, as the bees are much more likely to be cross.

It takes an experienced beekeeper usually to judge a queen by appearance. You can tell a good deal by the color and size, but the best way for you to judge would be to observe the work of the queen. See whether the eggs are in regular order, whether the brood is largely worker brood, etc. A very old queen may lay too large a proportion of drone eggs, or an inferior queen will lay irregularly.—ED.]

Why no Egg-laying in the Fall?

The bees that I got during early fall were all right. The queen did her duty by laying eggs enough to satisfy me, but for two or three weeks there has been no brood. Should I expect any at this time of the year?
MRS. SUSAN E. ALLEN.

Wheelerville, Pa., Oct. 10.

[Under normal conditions the average queen in the North three months or more old will stop laying in the fall. Only young queens, thirty days or younger, will lay during the months of September and October in northern States. The condition you find is about normal with your bees. During cool weather it is best for the queen not to lay, as the bees, in their effort to take care of the brood, spread the cluster too much, and this kills some bees, and at the same time allows the brood to die.—ED.]

The Colony-odor Theory Doubted

I have not been able to accept fully the colony-odor theory that one reads of so much in bee literature. June 15, p. 419, Mr. Cargo says, "In one case, bees in an upper brood-chamber left their hive while it was set aside a few moments, and attempted to return to their regular entrance below, and were killed." I understand that these bees from the upper story, finding themselves separated from the rest of the colony, took wing and returned to the entrance of their own lower story, and there were received as foes. Why did not their colony odor protect them?

Two days ago I shook the bees of a hive which I had "Alexandered," as they had destroyed the cell I gave them, in front of the hive of their own mother, hoping to have them help her colony store some basswood honey. I had to leave them immediately after shaking; but on visiting the hive the next day I found the piece of burlap on which they were

shaken covered with dead bees. Colony odor didn't seem to cut any figure there.

At other times I have shaken strange bees in front of weak colonies, or colonies I wanted to strengthen, and they were received kindly, despite their strange odor(!).

J. F. W. ULRICH.

Hasbrouck Heights, N. J., June 23.

Learning Bee Culture, Etc.

I am a boy of 21 years, and have been raised on a farm, and worked for my parents all my life. I have been reading GLEANINGS for over a year. Though I have never met you I feel as though you are one of my friends. I have been interested in bees for a long time; but the bee fever has got worse since I have been reading GLEANINGS. I got my first bees a year ago last August, and now have four colonies, and like to work with them better than any thing else. But I feel there is so much to learn about them before going in on a large scale that I am bothered whether to keep on at home with the bees or try to get a place to work in a large apiary under an experienced beekeeper. The bees have been storing very heavily this fall, and it has been so warm that some of the honey has been breaking down.

Metropolis, Ill., Oct. 13. HARRY RODENBERG.

[My good friend, as you state it I advise you to stay at home, study your A B C book and the journals, and from the yield of honey right here in the middle of October you certainly must have a splendid place for keeping bees. I know a good many would say, "Go and work in some big apiary;" and that might be a very good thing; but it would be a considerable expense, and, as you state it, I am inclined to think you would get along faster right where you are, providing your enthusiasm keeps up.

With the start you already have, I feel sure you can build up an apiary as fast as you have skill to manage it. Quite a few who have purchased a fair-sized apiary to start with, unless they have had much experience, have made a failure. If you could visit some beekeeper near you it would doubtless be of great benefit; but I think that in the end you will gain by working for yourself in place of somebody else. It is expensive to go away from home—that is, to stay any length of time; and your bees and other work would be likely to suffer also from your absence.—A. I. R.]

Reversing the Entire Body in Order to Get Combs Built Clear to the Bottom-board

I notice that you seem to have spaces at the bottom of the combs in your deep Hoffman frames; and as this causes some bother in finding queens, and takes up valuable space I should like to ask whether you have tried this remedy:

Take one of your bee-escape boards and cut an eight-inch round hole in the middle of it. Go to any fairly strong hive during a good honey-flow. Remove the supers and separator board; place your prepared board on top of the brood-nest; nail down, making sure to wedge the frames so that they can not move. Now turn the entire body upside down on the bottom-board and you will have all your frames filled out full in a few days. Try this once, and I am sure you will like the plan.

Shellman, Ga., Aug. 22.

D. W. HOWELL.

[The plan here spoken of has been used to quite an extent. Along in the early 80's reversing was thought to be the panacea for all the ills that confronted the beekeeper. It was claimed that it could be used to destroy queen-cells, which it did not; that it would check swarming, which it also failed to do; that it would force the honey from the brood-nest into the supers. This it did accomplish to a considerable extent. There is certainly one thing it did do, and that was to get the combs built clear down

to the bottom-bar. The Danzenbaker hive accomplishes this last feature very nicely, because the frames are reversible. But in later years very little importance, comparatively, has been attached to the matter of reversing. However, one can get the combs of the Hoffman-Langstroth frame built clear out to the bottom-bar as here explained.—Ed.]

A Statement

On page 567, August 15, Doolittle is asked the question: "Did you read on p. 503, GLEANINGS for July 15, that the 'first queen-cell is likely to hatch on the ninth day from the time the prime swarm issues'?" The above quotation is what was added to the title of my article on that page. The title of my article was: "The Control of After-swarms." The other part of the title as it stands on that page was added by some one else. In my article I did say in one place "due to hatch," when I should have said, "due to be hatched." But then I immediately qualified it by saying, "That is, the forenoon of the ninth day after the first swarm in an apiary issues, a young queen is quite likely to be hatched." It was not the time of the queen's hatching that I was concerned about, but the time to look after the colony to prevent after-swarming. There is no discord when understood.

Huntington, Ind.

J. W. SOUTHWOOD.

Scarcity of Drones Retarding the Swarming Fever

Does it not seem reasonable that a hive running over with big clumsy noisy drones suggests that the home is a bit crowded?

Douglas, Ariz., May 21.

M. CLYMER.

[A superabundance of drones might suggest a crowded hive, but not necessarily so. In many cases, at least, their presence is due to a failing queen whose eggs are producing a large percentage of drones rather than workers. They may also be due to a large amount of drone comb in the center of the brood-nest during a honey-flow. At such times a normal queen, especially if she is a year or more old, will lay in drone combs almost as readily as in worker combs, and especially so if swarming is in prospect. In modern management there is no excuse for an excess of drone comb in the hive. It is a big waste of bee energy that might be better utilized in the production of worker brood.—Ed.]

Painting Hives while the Bees are in Them

Would it harm the bees or brood to paint the hives with pure white lead and linseed oil while the bees are in the hives? or is it best to move the bees into a new hive while painting the old hive?

Do gentle bees gather as much honey as ugly ones under the same conditions?

Will blooded Italian bees winter as well as hybrid or native black bees under *bad* conditions?

Which is the larger bee—an Italian or a hybrid?

Marshfield, Wis., Feb. 14. JAMES MAXWELL.

[You can paint the hives almost any time, whether the bees are in them or not; but if the painting is done while the bees are flying we recommend leaving the alighting-boards until after they are all in the hives at night. In the morning the paint should be dry enough to make no trouble. Always remember to apply very thin coats of paint well rubbed in.

Gentle bees may gather just as much honey as irritable ones, although it is true there is a danger in breeding for gentleness alone to secure bees that are not worth as much, so far as being able to gather honey is concerned, as other bees that are better hustlers. There is no reason, however, why the best workers in the apiary may not also be gentle.

Pure leather-colored Italians are just as hardy as hybrids, for they came originally from northern Italy,

where the winters are severe. Our experience has been that the extra-yellow Italians are not quite as hardy on the average.

The size of the bee does not depend so much upon the race as upon the strain. If the stock is allowed to degenerate, the bees may be somewhat undersized. It has been claimed that bees reared in combs thirty or forty years old are also undersized; but we ourselves have not been convinced of this.—Ed.]

Five Years Record in Idaho; New Idea for a Feeder

We have had unfavorable weather for bees—some windy days, and too much rain. The first year I kept bees in Idaho I secured 31,000 lbs. of honey from 190 colonies; the second year, 62,000 from 400; the third year, 47,000 from 425; the fourth year, 65,000 from 500. Now in this, the fifth year, I shall do well to get 30,000 pounds from 500 colonies. I have increased to 750. That is some gain. We have worlds of feed. Still, I am not discouraged with the business. If I am once able to keep a stock of supplies on hand I can make a living from just such a year as we are going through.

I wish to give a suggestion for making a feeder. I use the wide entrances. It could be made of tin, and could be half an inch deep and about 10 inches wide by 15 long, so that it could be used in an eight-frame as well as a ten-frame hive. This feeder could be made corrugated, something like an old-fashioned washboard, only deeper. This would prevent spilling as each one of the little troughs would be separate. I think such a feeder could be made to hold from 1½ pints to a quart, and could be shoved right under the brood-nest. If the hive were level it would do no harm if it slanted forward. What do you think of it?

Rigby, Ida., Aug. 9.

L. A. COBLENTZ.

[Feeders of this type have been used, and there is no particular objection except that the syrup so nearly exposed is rather inviting to robbers.—Ed.]

Reply to C. W. Arnett; Sulphur and Salt Treatment for Diseased Bees

In reply to C. W. Arnett's query. Aug. 1, p. 548, I will say that I had one colony that acted the same way. I was at a loss as to the cause and cure. No Himalaya blackberries are there to my knowledge. In July I had a swarm develop paralysis. Hundreds were dead in front of the hive. I began by searching back in numbers of GLEANINGS for a remedy. I found where one apiarist sprinkled salt on the alighting-board. It helped somewhat.

I found, too, that an experienced beekeeper who transferred bees to another hive always effected a cure when sprinkling the entrance with sulphur, and salt did no good. I had to walk to town 2½ miles to get the sulphur. I mixed equal parts of salt and sulphur, and sprinkled the entrance four or five times that day. That ended the trouble.

I then thought I would try the same treatment in case of a colony that was acting similar to C. W. Arnett's bees. It cured that colony, and the bees stored honey as fast again after the treatment.

Colo, Iowa.

MRS. OSCAR TRIPP.

An Average Crop in Dixie

As our season is drawing to a close I want to send in a report on our honey crop from this part of Leedom.

With a very few exceptions there has been about an average crop of honey made in every section throughout Dixie.

Cordele, Ga., Sept. 5.

J. J. WILDER.

Our Homes

A. I. Root

Be still, and know that I am God.—PSALM 46: 10.

What is man that thou art mindful of him? and the son of man that thou visitest him?—PSALM 8:4.

But I say unto you, that ye resist not evil.—MATT. 5:39.

In our issue for Feb. 15 I gave you a sketch of my childhood days; and I mentioned one of my boyhood playmates who was greatly interested in electricity and chemistry as well as myself. In later years our ways were far apart, or since we were about twelve years old. But recently we have hunted each other up, and renewed the acquaintance of childhood. Below is a letter from my old friend "Corwin:"

Dear old friend Amos:—I wish to thank you for GLEANINGS that still reaches me regularly. I read your talks with interest, though, as I have told you before, I can not think that God, who has 8,325,000 suns with accompanying worlds to look after, according to recent estimates by our astronomers, is taking so much interest in you and a lot of young "toughs" who try to annoy you for riding in an old runabout auto. If you would get a six-cylinder, goggles, gauntlets, and a big cigar, and put on some "style" (even if it took a mortgage on the plant), you would not be troubled, and would only have to stop and pick the arms and legs out the wheels now and then. Yes, Amos, I was annoyed in the same way when I was driving my old pet horse years ago. It is all a question of style with the young Arabs.

It seems more reasonable and tangible to think that, when your prayers are answered, it is by some friend who is interested in you on the other side of life. The Rev. Lyman Abbott has said recently that influences come to us from the unseen. There is little that is tangible in your belief, and that is what is the matter with your churches. The little girl's definition in the enclosed clipping is too true.

Discussing the lamentable fact that, according to the last census, half the American people never go to church, Canon Hughes Scott recently said:

"The trouble is, perhaps, that Americans have a wrong idea about the church. They think the church wants them to believe a lot of outworn dogma. That is not true.

"Yes, the trouble is that the people define faith as the little girl defined it in school.

"'Faith,' the little girl said, 'is believing what you know isn't true.'"—Washington Star.

I am enjoying the best of health. No "meats" in mine. T. C. P.

My good friend, don't you suppose you could knock off a couple of millions from the figures you give? And who is it among the scientists and astronomers of the whole human family that have been able to figure out just 8,325,000? Why not say five millions or ten millions? Are we not all getting into pretty "deep water" when we attempt to let our imagination go out into space? Suppose the astronomer is correct, and that there are all of those millions of suns with their accompanying worlds. After having so many, what is there outside? In other words, how far does space extend beyond the heavenly bodies? This is an old,

old question. It has baffled the human mind ever since the world was created; and in contemplating this vast universe, no wonder the Psalmist broke forth in the language of our text—"What is man that thou art mindful of him? and the son of man that thou visitest him?"

It is a stretch of faith, I admit, dear old friend, to believe that God has in mind each and every one of us. We might, for instance, suppose that all of these planets, with their millions of suns about which they revolve, are inhabited like this world of ours, and we might go on and question whether one God could oversee and keep track of it all. With our feeble and childish intellect we might suggest that there are many gods as do the heathen. But would that help the matter any?

There is another text in Isaiah which says, "For my ways are not your ways, neither are my thoughts your thoughts." And in all this groping with the imagination, shall we not recognize or keep in mind that the only one true God is incomparably beyond humanity, even our best specimens, and beyond human comprehension? If we fail to comprehend space, is it not likely we shall in like manner fail to comprehend God? Our days are but few—that is, here on earth, and his are for ever and ever. If all the books on astronomy and theology were collected together they would give us no information that touches or comes anywhere near the Bible, God's holy word. Whatever we may say about the Bible, or think of it, we must recognize that it is unlike any thing else; and it is not only unlike any thing else, but it holds up a higher standard of morals than do all the books together in this world of ours. Wherever the Bible goes, civilization goes with it, and progress also, such as our own nation is making just now.

There are many bad things and bad people in this world of ours; but notwithstanding all this, is it not generally true, as we have it in that brief legend on our coins, "In God we trust," that this great and adorable being has sent just one messenger here to earth—his only Son? and the message brought is not only unlike every thing else, but it is above and beyond every thing else.

We started off to consider prayer. Jesus' little flock of followers were once worried about this very matter of prayer. They came to him and said, "Lord, teach us to pray." While we have all of us repeated

this old prayer so many times that it falls on our ears, I fear, without meaning, it is a wonderful prayer after all. I wonder if the Holy Spirit will give me grace and wisdom to present it to your view from a little different angle or view-point. I have often wondered if the dear Savior considered or waited a while before he gave us that brief petition for a copy. I am inclined to think he gave it offhand. First, he says, "Our Father who art in heaven." What does that mean? First, we are told that God has a dwelling-place, and that his dwelling-place is heaven. There has been a good deal of talk about heaven here on earth; and I am quite in agreement with the statement that we can have both heaven and hell here in this world, and it is largely a matter of our own choosing. Well, Jesus told us that all prayer should be addressed to our Father in heaven. What next? "Thy kingdom come, thy will be done on earth as it is done in heaven." Heaven is not only God's dwelling-place but his kingdom, and God has subjects there. They are loyal, faithful subjects, trusting in him—a place where his will is the constant effort of every one of his subjects.

We might speculate as to what sort of place God's kingdom is. Now, I need not try to explain it, for the dear Savior spent a lot of time in trying to explain to his faithful followers what God's kingdom is like, as we see in the 13th chapter of Matthew. Get the good book and go over it yourself. Now, Corwin, you and I speculated sixty years ago as to what the future would be here in this world, or after we had left the world. I suppose that, during all of our separate lives, we have wondered and conjectured as to what we are here for. What is to be the outcome? What does God expect of us? What did he expect when he created us and gave us our physical bodies and our mental and spiritual intellects also? Is it at all reasonable to suppose that he would lose interest in man, the crowning work of his creation? You and I have witnessed the wonderful developments in electricity, X-rays, radium, etc. Are we to drop it when old age comes on and we pass away? God forbid.

I forgot to mention, when I quoted the first word of that prayer, we are told God is our Father. A father never loses interest in his children. His whole life, as a rule, is spent in making the best provision for them he knows how. God is our Father. Are these busy lives of ours to be all there is of it? Shall we never get a better glimpse of astronomy than we have here from our comparatively small and narrow standpoint in the universe? God forbid. I fully ex-

pect to get a glimpse of these "eight million suns" you have talked about, far, far beyond and above what any telescope can reveal in this world of ours.

Did you ever stop to consider how many times Jesus promised over and over "everlasting life," or eternal life—a life beyond the lives we live here? He kept saying it over and over, in substance, "Whoso liveth, and believeth in me, *shall never die.*"

Now to get back to where we started. Is it possible that God can recognize and listen to us individually with all the responsibilities he has on his hands?

Last night in closing down our wood-working factory some of the machinery gave out. In fact, we are just now at work putting in different boilers and a new engine. I was away when the mishap occurred. When I arrived home I questioned as to whether the hands had been notified that we could not start up our wood-working machinery in the morning, and I fear our people did not consider it as a very serious matter for a lot of good faithful hands to come here with their dinner-pails without expecting they would have to be sent back home. The matter worried me so much that I awoke several times in the night. Twenty minutes before the whistle blew I stationed myself near the entrance at the time desk, and explained to each man and boy the condition of affairs; and with the help of other members of the firm we studied up work that needed to be done about the premises until they all had a job; and I did not breathe easy nor feel happy until each one who wanted work was started. There was seasoned basswood to be taken down from the hill; and in order to have the teams and wagons in readiness I was up before five; but it was quite a responsibility on my old shoulders to plan some useful work for toward a hundred people until the "wheels could go around" once more. Some of you may laugh at the idea of being responsible for only a hundred or less workmen. Down at the Panama Canal, now nearing completion, Goethals had charge of something like ten thousand men. We had to ransack the world, however, to find a man who was great enough and big enough to undertake the task. He is now finishing it, and it promises to be one of the greatest triumphs of the world and of the age. Our country is producing such men; but I confess there are only a few of them.

Now, dear old friend, we might try (but that is about all we could do) to comprehend a being who can lay plans and keep in mind the best good and the well-being of all the people in this great world, or some-

thing like 1400 million. Of this great mass of humanity about 450 millions are Chinese; and my impression is they need quite a little "looking after," with their idolatry and superstition. If I am right, God created them also, and planned a glorious outcome for that heathen nation; and, thank the Lord, that glorious outcome is already in sight. Now, can we not step still a little higher up, and have faith to believe that he who has created the universe will finish the task he has undertaken? * Washington, Lincoln, and other great men of our nation, have been, and our present incumbent is, a believer in God and in prayer to him; and I believe the intelligence of the people of the United States regards prayer as a mighty force in the affairs of the world. Every little while somebody comes to me or writes me something like this: "Mr. Root, your little prayer, 'Lord, help,' has cheered my life and helped me to surmount a lot of trouble." Jesus urged at times almost vehemently that his followers should watch and pray. He says, "Ask, and ye shall receive;" and he tells us also that "the Lord pitieth them that fear him."

Now a word in regard to the "street Arabs," as you are pleased to call them. I want to say to our readers that I can imagine a twinkle in the eye of my old schoolmate when he speaks about picking

the "arms and legs" out of the wheels, etc. I admit these small boys are often provoking. Now, we who are older should keep constantly in mind that boys can be taught like ducks and chickens. A little teaching prompted by the Devil would induce them to puncture your automobile tires and do other mischief to the machine. Another kind of teaching will make those boys your friends instead of enemies.

I once became discouraged about a boy whom I had labored with repeatedly, apparently without success. A Christian lady said to me something like this: "Mr. Root, Jesus died for him." It set me to thinking. When we feel vexed and provoked at these boys' antics, let us stop and consider that Jesus died for them. He died that they might be made better.

I am soon to go back to my Florida home, and I suspect I shall have more trials along this same line. Satan has found out that he can trip me up, for he has tripped me up in times past. Dear friends, you who believe in prayer, and have had your prayers answered, will you not pray for me and for those boys, all of them?

Now just a word in conclusion about unpromising boys. In looking back through sixty years I remember quite a few that I pronounced at the time "no good." But years after, when I heard from one and another that they had climbed to positions of excellence, it was one of my "happy surprises." One especially I have in mind that vexed me repeatedly because of his awful indifference and heedlessness. I have just been told that he has made some valuable invention worth thousands of dollars to manufacturers of automobiles. I said when I first heard of it, "Why, no; it can not be that that boy has become a great inventor?" Perhaps I did pray for him in his youth, but if so I am seriously afraid I have forgotten about it.

Shall we not wind up, dear friends, with that beautiful injunction from the dear Master, so wonderfully hard for poor humanity like you and me to carry out? "Love ye your enemies. Do good to them that hate you. Bless them that curse you, and pray for them that despitefully use you."

Blind unbelief is sure to err,
And scan his works in vain;
God is his own interpreter,
And he will make it plain.

Later.—Just after the above was dictated, this letter was placed in my hands, and from it I make extracts of three paragraphs:

Dear Sir and Friend:—Yesterday's mail brought me from some source a marked copy of *The Flaming Sword*, covering a four-and-a-half column of super

* Now, while we are contemplating the great Ruler of the universe let us try to comprehend that this Creator is also *Father*; and while doing so let us listen to the words of the dear Savior when he says (Matt. 10:29, 30, 31), "Are not two sparrows sold for a farthing? and one of them shall not fall to the ground without your Father. But the very hairs of your head are all numbered. Fear ye not, therefore; ye are of more value than many sparrows." With all God's care of this vast universe, is it not comforting that we are in his sight of more value than many sparrows? If we reject those beautiful words of the Master as too wonderful and too impossible (if you will excuse the expression) what shall we do? Do you remember what Peter said when the Lord asked them if they too were going to turn away? "Lord, to whom shall we go? Thou hast the words of eternal life."

Our older readers will recall that I have often mentioned a small particle of radium that I have had in my possession for several years. Suppose you take a cambric needle and touch the point to a drop of white paint. With a magnifying-glass you could just see a speck of paint on the needle-point. Well, my particle of radium is about the size of that speck of paint. It can be seen only with a magnifying-glass. But, small as it is, it has been day and night, winter and summer, year after year, throwing out showers of shooting stars. They continue to pour forth in every direction like a water-spout, and yet the radium is not exhausted. The "bombardment of meteors," as it has been called, is in no way diminished. I put it in a dark room three or four days ago, and got up in the middle of the night, and there it was blazing forth in undiminished splendor. So far as I know it will go on in this way for ever and ever. Scientists are nonplused and appalled. It upsets and overturns old theories. Now, is it too great a stretch of the imagination (backed by the words of the dear Savior) to believe that God's love for the creatures of his handiwork—for mankind, his greatest and final creation—is it too great stretch of our faith to believe that God's love and care can go out unceasingly in the same way toward his children?

ficial absurdity in an attempt to ridicule your belief and that of the Christian world in the power of prayer.

The mother or father can think and speak from a living soul-inspired experience on the intensity of parental love. To all others, the measure is one of imagination and speculation. So with the Christian soul in the realization of the Father's presence as the guiding influence of his life. He has an inward knowledge of the power of prayer and the assurance of an answer that mystifies the groping speculator and puts the cynic to confusion. [Amen to the above.]

Just one more question: How long would it take

for *The Flaming Sword* species of reasoning to abolish slavery, wipe out the white-slave traffic, or accomplish any other moral reform?

LEWIS P. TANTON.

Charlottetown, P. E. I., Can., Nov. 23, '12.

Perhaps I ought to feel complimented to think that any periodical should devote four columns to try to set me right. But I think it would take a great deal more space than that to persuade devoted Christians that God does not answer prayer.

High-pressure Gardening

"HIGH-PRESSURE" GARDENING IN OCTOBER.

Let us not be weary in well doing; for in due time we shall reap if we faint not.—GAL. 6:9.

There are a good many disappointments—yes, grievous disappointments—in gardening. We might expect, however, that in high-pressure gardening we get rid of the disappointments. And it *does* get rid of a large part of them, but not all. In our locality here in Medina, along the last of September and during October, much trouble comes from frost. I was particularly anxious this year that the frost should hold off because of the dasheens I have told you about; so I was watching the thermometer and barometer with great anxiety whenever there came a cool night. Do you want to know what the barometer has to do with frost? Well, it is this: Along in the fall of the year especially, the barometer usually drops for a warm spell, and rises for a cool spell. When it runs away up, oftentimes a day or two before, it indicates a probable frost. On the 22d of September there was a little frost on the boards and other exposed places. Next morning I told the children that I could tell before noon pretty surely whether we would have a frost. The barometer was rushing away up, indicating a clear sky. The wind was in the northwest, and by 3 o'clock the temperature was down to 50.

One of our rules in the care of tender stuff is that, when the mercury stands at 50 or below at sundown, there is danger of a frost. This is not always true, but it comes so near it that it is pretty safe to rely on. Well, after three o'clock I told them all to hunt up their empty jute grain-sacks and cover up the stuff. The dasheens were my principal anxiety. I found two large sheets which we use to cover stacks of grain, etc., which I spread over the dasheens as well as I could. But they were so tall that the sheets were not large enough to tuck down around the edges. The consequence was, the dasheens were nipped almost as badly

under the sheet as elsewhere. After the frost was over, however, and the sun was up so I could see how much they were damaged, I went round with a sharp sickle and cut off the injured leaves. I think this was a profitable thing; for where I missed a leaf or portion of the stalk that had been frosted, it rotted down quite a piece beyond it. Where I clipped off the injured part, the stalk as well as the leaf, the effect was nothing more than a severe pruning; and when a longed-for shower, right after we had been having a severe drouth, came on the 28th, and lasted two or three days, the dasheens picked up amazingly; and to-day, Oct. 11, most of them have put out new leaves, and seem to be growing almost as well as before the frost, for we have had almost two weeks of real summer weather since the big rain of September 30.

Now, just below the dasheens were the six tomato-plants that I have mentioned—Green's hybrid. These plants were loaded with green fruit when the frost came, or, rather, they were sprawling all over the ground, full of fruit almost ripe.

Now, here is a matter that comes in, in regard to training tomatoes on a trellis. When I saw the enormous amount of tomatoes they were going to give us, I felt sorry to think that these were not trained on a trellis; but when the frost came, I saw at once my clean hard clay ground was the thing after all. All I had to do was to get a lot of empty burlap grain-sacks and blanket the plants. Although the surface of the sacks was white with frost, the tomatoes were not hurt a particle. You see, the warm ground was a protection from below, and we have been having basketful after basketful of the finest tomatoes of the season, notwithstanding the big frost. The warm sunny days, with a temperature a few times up to 85, just suited the tomatoes. Below the tomatoes were the cantaloup melons I have spoken of. I did not have grain-sacks enough to cover these; but, al-

though the frost killed the green foliage, the warm ground kept vitality enough in the vines to ripen up the cantaloups finely; and I have been having a nice cantaloup with my apples for my five-o'clock supper all through September and the first week in October, and all that from a five-cent package of seeds and some of that rich old rotted stable manure I told you about. The same is true with the Hubbard squashes. There are twenty-six, most of them great beauties, from a five-cent package of seed.

Lying close to the dasheens were our Early Ohio potatoes. When I soaked up the ground between the rows of dasheens with this heavy mulch of old manure the water flowed on to the rows of potatoes, and we had a big yield; but, sad to relate, the heavy application of stable manure made them so scabby, crooked, and ungainly, that many are almost unfit for use. Both the Early Ohio and Early Rose potatoes are bad on our ground in respect to scab; and although I am a potato crank, or used to be, I have not dared to show to visitors nor to anybody else my crop of potatoes. But, just wait a little. I have something else to tell you about potatoes. Before new potatoes were fit to dig we purchased some fine handsome Carman No. 3. They may have been only the Rural, of which the Carman is a seedling, but a much handsomer potato. After we began digging our new potatoes there were a few of the Carmans left in the cellar; and although it was the middle of July I decided to plant them. I had one row up near some tall evergreens. When I planted them I had a kind of feeling that I was wasting my time, because I thought the evergreens would rob them of moisture and fertility. Well, when the frost came they were growing very luxuriantly; but although the branches of the evergreens did not reach very near the potatoes, in some way the big trees kept off the frost, and the potatoes grew right along until this morning. As the vines were dead, I dug the potatoes, and it was one of my "happy surprises" to find great beauties, almost as smooth and handsome as new-laid eggs, and not a trace of scab anywhere. Just a few days before, Mrs. Root urged me to grow potatoes on some other ground, because our garden had grown potatoes ever so many years, and the ground must be badly infested with scab. Now, can anybody tell me why these Carmans escaped scab entirely? Was it because they were planted so late, or had the branches of the evergreens something to do with it? Was it because the potatoes were of a different variety? I should be glad to know.

Just below the cantaloup melons there

were six egg-plants, and to them too was given some of that old manure; and I think some of the water from my irrigation got down there. We had a dozen of the largest and finest egg-plant eggs I ever saw. One was so large that we divided it up and sent parts to our neighbors. These too were made to give a big yield of fine eggs, in spite of the severe drouth, by digging the dirt away from each plant clear down to the fine white hairy roots. Then the manure was sifted down all through these roots, and the whole well soaked up with a watering-can, and soft dry dirt was hoed up after the watering.

The success I met with almost all of my crop has required some hard and faithful work; but the hard work, taken a little at a time, was just what was needed to give me inspiration to make these pages you are looking at helpful. Is there not a wonderful truth in the latter part of my text—"In due time we shall reap if we faint not"?

"HIGH-PRESSURE" CORN CULTURE.

Some years ago, on a visit to our Ohio Experiment Station, I was shown a long field of corn. The field was long enough so that each row was planted entirely with a single ear of corn. The professor who was with us called our attention to one row that stood almost entire the full length of the field, with scarcely a broken stalk; but owing to a hailstorm a few days before, the rest of the corn was broken more or less. Some rows were almost or quite all snapped off by the wind. Now, by selecting seed from this row that stood the blast we could readily get a field of corn that could not be easily blown down. But in getting such heavy stalks to stand the blast, we might cut down the number of bushels. They were then experimenting on this very thing, and the matter was dropped to look at something else. Well, the periodical called *Corn* (Waterloo, Iowa) has a wonderful picture in its October number. A like number of kernels were taken from two ears of seed corn. The corn from one ear gave a bushel box full heaped up—stacked away above the top. The corn from the other ear, side by side, and exactly the same treatment, gave only a peck of inferior corn. What do you think of that? When a farmer goes to his cornerrib and selects his seed corn, there is no way in the world for him to tell by the looks what ear will give a peck and which will give five pecks. The farmer who takes time by the forelock, and plants some whole ears a year or two years before, and saves seed from the ear that gives the biggest yield of nice corn, will,

by keeping this up, soon have a "pedigree" strain of corn that might not only give him double the crop, but four or five times as many bushels as if he stupidly followed luck and chance. Dr. Miller, in one of his *Stray Straws* for Oct. 15, calls attention to this same thing; and it is going on, not only with field crops, but in our egg contests that are now being exploited, and reported all over the world.

From every State comes the complaint that, while experiment stations are making such wonderful discoveries, and taking such pains to send out bulletins to the farmers, a great lot of these same farmers never visit their State testing farm at all. Over and over again I say to my farming friends, "Surely you have been down to the big farm at Wooster?" Almost invariably the answer is that they have talked about it but have not had the time. Sometimes this is the case when they could get there in two or three hours. The Department of Agriculture, recognizing this, is now, at least in some States, sending competent men around among the farmers to teach them high-pressure farming. You need not come back to me and say the farmers sometimes know more about farming in their own locality than the government experts. Look at that picture I have referred to in *Corn*, and then own up that you have been stupidly farming with your eyes shut—yes, with your eyes really shut to what is going on in developing new and better strains of seed corn.

THE LOGAN BERRY, OR BLACKBERRY RASPBERRY.

Some years ago I was greatly pleased with the Logan berries of California. In fact, they were so plentiful (and I presume they are yet) that they were on all the fruit-stands in the streets of Los Angeles. They tasted much like a great big luscious raspberry more than any thing else I can think of, and very much resembled the Northey blackberry that I made such a fuss about down in Florida. By the way, it is no more than fair that I should tell the readers of *GLEANINGS* that there has not been a good yield of this wonderful berry since I gave it such a write-up. Anthracnose, or something similar, attacked it on my ground, and on the grounds of my neighbor. Neighbor Raub, who, however, had two or three small clumps of berries in his garden to which he gave extra care, fertilizers, and watering, got some beautiful nice berries. Spraying might remedy the trouble; but I have not been able to learn whether anybody has tried it. Well, now, let us go back to the Logan berry of Cali-

fornia. Several have been inquiring of late in regard to it. Green's *Fruit Grower* says it has not been a success in the East, nor in cold climates, so far as they can discover. But there is no reason in the world why it should not be a success in Florida, unless, indeed, this same anthracnose should attack it. I am going to submit the matter to friend Reasoner, of the Tropical Nursery. By the way, the berries are so plentiful that Sears, Roebuck & Co. catalog the canned berries. A good-sized can is only 20 cts., and they are certainly a most delicious fruit, larger, if any thing, than average blackberries.

DASHEENS: THE FINEST IN FLORIDA EXCEPT THOSE AT THE BROOKSVILLE GOVERNMENT STATION.

Mr. Root:—I send you a picture of my dasheen, taken Sept. 13. The plants average between six and seven feet high, and cover the ground completely. The tops have not grown perceptibly for several weeks past; but the tubers are forming rapidly, and promise a heavy yield.

The soil on which they grow is a well-fertilized humus-filled sand. I ridged the soil with furrows about six feet apart, planting two rows of dasheen to each ridge. The soil is so moist that there has been more or less water in the bottom of the furrows all summer.

Neighbor Ault's dasheen, with a glimpse of friend Ault and the banana-plants in the background, just above his head.

As to the quality of the dasheen as a food, we have boiled and roasted them; and while they are fine grained, and of fair quality, we prefer a good Irish potato. No doubt they will be more palatable when fully matured.

Bradentown, Fla., Sept. 30.

Later.—A man by the name of Young, representing the State Agricultural College at Brooksville, called to-day and took some pictures of my dasheen. Mr. Young noted the size of the plants and the method of cultivation, soil, etc., and he said that he regarded my patch of dasheen as the best in the State, with the exception of some at the college farm at Brooksville.

When I asked Mr. Young his opinion in regard to the food value of the dasheen he said he thought it was going to be of great value, especially to Florida. He said the dasheen is at its best when fully matured, and when dug they should be aired and dried for a few days.

We have had no rain, until now, for several days, and the air to-day was delightfully cool and pleasant.

Bradentown, Fla., Oct. 3. ARTHUR E. AULT.

The above corroborates what I have said about dasheens before perfect maturity. They are very fair eating, but nothing like the hard, solid, matured tubers sent me by the Department. The young shoots, however, and tender leaves, are all right, and make a very good substitute for mushrooms or oysters, with a few crackers added. The writer of the above, Mr. Ault, is a near neighbor of mine; in fact, his place is just on the other side of my fence. The dasheens he mentions grew on the same damp piece of ground where I found those wonderful Northey berries described in GLEANINGS about two years ago.

DASHEEN SEED—WHY IS IT NOT IN OUR SEED CATALOGS?

Ever so many are asking the above question; and for the first time I find a brief mention of it in a seed or plant catalog for the spring of 1913. This catalog of plants has just this brief mention, and nothing more:

"Dasheen, similar to the caladium, 10 cents each."

As the question recently came up in GLEANINGS as to how long dasheen could be kept for seed, the following letter answers the question:

Mr. A. I. Root:—Here is a dasheen of last year's growing, which I am sending you to show its keeping qualities. It passed the winter in the cellar in a basket with the rest of my crop, and has been lying through the summer neglected on a shelf in the cellar. So far as I can see, it is still perfectly sound and able to grow, unless for the fact of its bud having been broken off. I broke it off to see for sure whether it was still fresh.

The root, as you see, is very small. It had to undergo a dry summer in dry ground, so that the plants attained a height of only about seven or eight inches. The roots were, therefore, all small, but were solid, kept well, and grew vigorously when planted. They are of the Japanese variety. This year I planted also some tubers of a West Indian variety, which supposedly is not so well adapted for so far north as this, yet they are making a slightly

heavier growth than the Japanese; and the Japanese, in spite of the excessive drouth, have done better this year than last.

B. C. AUTEN.

Oronogo Fruit Gardens, Carthage, Mo., Oct. 1.

The above came to hand in perfect condition apparently, and I think there is no question but that it will grow; and if so, this settles the question that, when properly cared for, the seed will keep as long as a potato, or perhaps still longer.

Please note what I told you last winter—that where the bulbs are dry and hard it ordinarily takes three or four weeks for them to shoot up through the ground.

DASHEENS GROWN IN OHIO; E. C. GREEN, OF THE HYBRID TOMATO, GIVES HIS OPINION.

Friend Root:—Thanks to your kindness, a few days ago I enjoyed a treat that I think would have pleased many of the readers of GLEANINGS—a meal of Ohio-grown dasheens. The tuber we boiled as we did potatoes, which was, perhaps, not best; and as they were not ripe yet, they did not please us as well as good potatoes. But the tops cooked as asparagus were a "happy surprise," for thy compared favorably with mushrooms. When the fall-bearing strawberries were introduced I did not get as enthusiastic about them as many, for I thought if they came in competition with peaches, pears, grapes, etc., they would have a hard time; and this has proved true, I think. So with the dasheen. The tuber which will have to compete with the common and sweet potato will have to be extra good; but if the tops compare only with mushrooms they will certainly be a fine thing, for it is always hard to get enough mushrooms.

Stephen (my son) was up from the Experiment Station when we had them cooked, and he said, "We shall certainly have to try them at the Experiment Station next year."

Medina, Ohio, Oct. 15.

E. C. GREEN.

I will explain to our readers that I gave neighbor Green a whole plant, of course not fully matured. I think it was the large central corm he boiled as stated. These we do not find very toothsome; but the side tubers cooked with or without the green stalk and stem we think splendid food, and we are having them almost every day.

THE AMADUMBE, THE DASHEEN OF SOUTH AFRICA.

SEE PAGE 740, OCT. 15.

Mr. A. I. Root:—Whether these amadumbe will prove to be identical with some of the dasheens that you have I shall be interested to learn. Note every one who tastes them for the first time likes them very well; but not only natives, but children of missionaries and of settlers, who are brought up with them, are very fond of them. These are several varieties here that are eaten, and others that are so coarse and watery that they are not considered fit to eat. These are of the variety that we consider the best.

W. L. THOMPSON, M. D.

Mount Silinda, Melsetter, S. Rhodesia, S. Africa.
August 30.

TOMATOES—HAVING RIPE ONES IN NOVEMBER.

My wife and I take and clean or wipe them off (the green tomatoes) before the frost gets them, and then wrap them carefully in tissue paper and lay them in small baskets only two deep, and store away in a dark cool closet, and about Thanksgiving they will ripen, or sometimes later.

Cleveland, Ohio, Oct. 13.

JOSEPH BECVAR.

CEMENT HOT-BEDS, ETC., FOR EARLY TRUCK.

On page 589, Aug. 15, I spoke of James Hilbert's cement hot-beds or cold-frames. You will gather from the clipping below, from the *Grand Rapids Press*, that he has made quite a success by starting stuff under glass and carrying it to market with a motor truck.

HE GETS \$400 AN ACRE FROM TRAVERSE FARM; JAS. HILBERT, USING MODERN METHODS, WINS BIG YIELD FROM VARIOUS PRODUCTS; HAULS WITH THE MOTOR TRUCK.

TRAVERSE CITY, Oct. 3.—That intensive farming in western Michigan pays has been conclusively proved by James Hilbert, who owns a large farm northwest of the city. Last spring he planted an acre of Osage muskmelons, the plants of which he started under glass in order to have them ripe in time for the fall market.

During the summer the plants secured a good growth, and on Sept. 1 he brought his first load to town and sold them to the merchants. Since then he has marketed a load every day; and after he had sold his load to-day his figures show, after having kept a careful record, that he has made \$300 from the crop from this acre of land, and still has several more loads to market before the total crop is harvested.

USES MOTOR-TRUCK.

Good as this record is, he has done still better with a third of an acre of mango peppers from which he has already marketed a product that has brought him \$170, and they are not all harvested yet. He is even prouder of the returns he has received from an acre of Earliana tomatoes, from which he has supplied the local trade during the season. This acre has done better than his acre of melons, for the total receipts for the season reached the \$400 mark.

Mr. Hilbert delivers his produce to the merchants daily, bringing in every morning a motor truck load of all kinds of vegetables and fruit in season, and he is looked up to by the grocers as one of the essentials of their business. His farm is also famous for the onions he raises, and which he keeps in a large frost-proof cellar and brings them to town as they are needed by the grocers. Mr. Hilbert pretends to be no more than an ordinary farmer who gets results by knowing his business and sticking strictly to it at all seasons of the year. In keeping his books he has as perfect a system of accounting as any mercantile house, and does nothing by guesswork.

GARDENING FOR "PROFIT."

After what I said about gardening for profit in our issue for Sept. 1, I came across the following in the *Rural New-Yorker*:

On many farms you may find an old man or a man in poor health, or perhaps a cripple. These men are usually unable to go into the field and do a full day's work at hard labor. Some of them, denied the power to do this, feel that life has cast them aside, and I have seen them grow unhappy and bitter at their prospect. If these men would but think so they could take a small piece of land, fit it for a garden, and do wonderful work upon it. The labor would be well within their powers, and the results far beyond any thing they ever reached at plain farming. For you see gardening is higher farming; and many of these older men would renew something of their youth and courage in the thought that they can force one acre to produce more than ten acres ever did in their old system of culture.

Not only would this garden become a wonder, but it would finally improve the entire farm. It would be an object lesson showing what can be done if the soil is only well handled. Before long the boys would see that garden, and begin to ask themselves why they should work three acres in half-way fashion when, by applying something of garden culture, one good acre would give the same crop. That is what a good garden will do; and the older man would find that this higher farming has enabled him to influence the farm as he never did before. These are only a few reasons why every farm should have a good garden. Had you been with us for dinner on the Sunday I speak of I could have piled up your plate with a dozen convincing arguments.

Do you see the point, friends? These old men, after they get through gardening for profit—that is, for dollars and cents—may work (as we read about in the good book) for treasures laid up in heaven; for whenever we get to a point in our lives where we are working for humanity and the coming generations is it not really for "treasures laid up in heaven where moth and rust doth not corrupt, and where thieves do not break through nor steal"?

NOT ONLY A BOYS' CORN CLUB BUT A GRAND-FATHERS' CLUB.

We clip the following from the *Monthly Bulletin* of the Ohio Department of Agriculture:

My dear Mr. Sandles:—I have just been reading your hair-raising report of the "boys' corn-growing contest," and am glad of the "boys' corn-growing." But it pains me to think and know that in Ohio there are hundreds of boys who never saw a hill of corn grow.

This year I wish the poor and honest lad could be placed on a par with the rich man's son. What do I mean? Why, I mean this: If a boy produces 60 bushels of corn at a cost of 15 cents per bushel, I claim he has achieved far greater results than the lad who produced 100 bushels at a cost of 50 cents per bushel. Let the lad who has nothing to buy fertilizer with stand on the same footing with the boy who has fertile soil and a rich father to back him. Again, why not have a "grandfather's club contest," all over 60 to enter? Give them a chance to see Washington. They will soon pass over the "Great Divide" into the border land. "Oh!" I hear you say, "their lives are almost spent, and they are not worth fooling with." Listen! Perhaps they were handicapped. Lack of capital; lack of ambition, hampered by richness, environment, and barren soil, they were not able even to flirt with success, let alone win her approval or favor. No grander, no greater, nor nobler sight could I behold than 88 gray-haired fathers, one from each county, taking their first and perhaps last trip to Washington, D. C., because they had raised the cheapest big yield of corn in their respective counties. What do you say, Brother Sandles? And we ought to offer a prize to the dear old grandmothers. God bless them! Let them raise a prize flock of chickens, or be a keeper of the tidiest and neatest home.

I am only a plain, seven-days-in-a-week farmer.
R. B. CARSON.

Amen to the above. But do not forget the dear old grandmothers while we have the grandfathers in mind.

Poultry Department

THE AJAX INCUBATOR; A CHEMICAL WHICH GIVES OFF OXYGEN WHEN BROUGHT IN CONTACT WITH WATER, ETC.

Mr. Root:—I read with great interest your note in regard to incubators, on page 18, of Special Notices in GLEANINGS. Exposing frauds based on pretended scientific discoveries which the common people do not understand, but think that, if it is "scientific," it must be all right, has always been a favorite work of mine, and I have exposed some notable ones, as I think your W. P. Root knows.

That the "Ajax vitalizer" has any good grounds for its claims I greatly doubt. I doubt the main assertion that eggs under a hen get more oxygen than those in an incubator. On general principles I should say that the opposite would be the case. But in regard to the tablets which give off oxygen when brought into contact with water, there are several substances which do this, the most notable being sodium peroxide. This, when fresh, gives off oxygen with such energy as to set fire to some combustibles; but I should not think it would be well adapted to the purpose in question.

Paterson, N. J., Sept. 20.

JOHN PHIN.

I did not mean to say there *is* no such substance; but in talking with those fairly well versed in chemistry they said they knew of none. Now, this apparatus for supplying oxygen to the incubator is supposed to throw a steady stream—just enough and no more to give the eggs vitality and to keep it up during the last two or three days of the hatch. I might explain to our readers that friend Phin has a lecture that he delivers in regard to the different methods of producing fire during all the ages past up to the present time. As a chemist he is well known in scientific circles. In our town of Medina we are using natural gas; and a little instrument costing only ten cents makes a light by rubbing a certain alloy over something like a file, somewhat like the old-fashioned lighting by means of flint and steel. The little ten-cent implement is kept close by the gas jet, and it saves both time and matches.

Later.—After the above was dictated the following came to hand:

I note what you say in regard to the Ajax vitalizer, which I have no doubt is as worthless as you believe; but there is a chemical made that liberates pure oxygen when brought in contact with water, just as carbide liberates acetylene gas. It is called "oxone," and is used to produce oxygen for the oxy-hydrogen light used in stereopticons and moving-picture machines. I know this because my firm sells it for that purpose, and I have so used it.

Louisville, Ky., Sept. 30.

W. C. FURNAS.

I have been hoping to get some good reports from this apparatus that has been so highly extolled in advertisements. The following, however, does not look very much that way, especially as it comes from such good authority.

In the April 15th issue of GLEANINGS you write up the "Ajax Oxygen Vitalizer." I wish to say I gave a thorough test on my Prairie State incubators, and they did not improve my hatch any; in fact, I

got better hatches without them. I gave them a thorough test, as I ran 35 machines; so you see I am in position to make a test.

Pleasant Valley, N. Y., Oct. 18. EDGAR BRIGGS.

COOKING FOOD FOR CHICKENS—ESPECIALLY THE GRAIN.

I very much enjoy reading your department in GLEANINGS, and find your poultry articles very practical and helpful. I have a way of economizing on cost of feed which has saved me a good deal of expense, so I will pass it along to you and your subscribers. My "secret" is to cook the wheat, which makes more than double the quantity when cooked. A quart of this cooked wheat will feed just as many hens as a quart of uncooked wheat, though of course it really was less than half a quart before cooking; and, besides, the hens seem to enjoy it better. I cook it in a wash-boiler on the kitchen stove when my wife is baking, so she uses the oven and I use the top of the stove, and it doesn't take any extra fuel and, besides, the hens seem to enjoy it better. I cook water to five quarts of wheat, and let it cook until dry. Sometimes to make it especially good I add meat scraps and red pepper, always a little salt. When I feed it I stir in some bran or alfalfa meal, and I give it to them in troughs or pans.

When the weather is as cool as it is now, I cook enough for three feeds at one time. It must not be kept till it sours. I use this only for the evening meal, making them work for their breakfast.

I keep thoroughbred White Leghorns exclusively, because I think they are the best layers in a warm climate, and are beautiful to look at out on the green grass. They are also beautiful in the show-room.

This fall at our Arizona State Fair I exhibited some of mine, and won several blue ribbons and the sweepstakes prize, a fine silver cup. Perhaps you would be interested in hearing of the record I made last year.

Starting Dec. 1 with 110 hens, I raised 95 pullets; and in August I sold some old hens, so the latter part of the year my flock numbered 150.

I sold 15,564 eggs. Of these 4249 went to the incubator trade for hatching, and the others were sold at prices ranging from 15 to 50 cts. per dozen. For all eggs sold during the year I received \$394.50 for hens, and fryers \$85.45—a total of \$479.95. Besides this we had eggs and poultry for home use. Of course the cost of feeding had to come out; yet even then it left me a nice profit.

Hens pay well here, but I believe that good hens well cared for are a profitable investment almost anywhere.

I hope you may live to see that hundred years—any way, a long time yet to continue your noble work of fighting the evil and encouraging the good.

Phoenix, Ariz., Dec. 2.

C. H. TRID.

My good friend, I supposed our experimental stations had decided by careful experiments that it does not pay to cook the food for poultry or other farm animals. A few years ago, as you may remember, there was a great craze for cooked food for domestic stock, and cooks were on the market for cooking, steaming, etc. Now, from the result you have given in the way of dollars and cents, we can not very well dispute your theory. From one to two dollars' profit from each laying hen in the year is certainly very good business; but if I am correct you have gone considerably beyond the highest figure.

Temperance

WOMAN SUFFRAGE—WHAT IT IS DOING FOR CALIFORNIA.

Mr. A. I. Root:—I am sending you under separate cover a copy of my local paper which contains the result of an election just held in our city. The liquor business was put down in this city about 18 years ago, and they have been fighting to get in again ever since. A few years ago they succeeded in electing a board of city trustees that gave the hotels and drugstores a license, after the advisory vote of the people was given against such a policy. Two years ago the people put the same board of trustees out of office by a majority of 450 votes, which was telling them most emphatically that they had not kept faith with the voters.

The present election was called by initiative petition circulated by the liquor interests, who called themselves the temperance party. This is the first time the issue has been clearly defined, and a fair and square vote taken. Notice what we did to them. We give the women due credit for this wonderful victory.

Redlands, Cal., Oct. 1. P. C. CHADWICK.

We should be glad indeed to give the full account of the reform the women have brought about in Redlands (as given in the clipping), but it is too long. No wonder the brewers and wet politicians are fighting woman suffrage. See below.

REDLANDS, CAL.; ALMOST THREE TO ONE AGAINST INTEMPERANCE.

Dear Mr. Root:—The temperance people of Redlands won a great victory Sept. 30, deciding by a majority of almost three to one against hotel permits and a wholesale liquor-house. For years our city has stood for good citizenship, for public improvements and moral uplift. Redlands has about 12,000 inhabitants, and is primarily a city of homes. Here people can safely come to educate their children. There are splendid churches, excellent public schools, and a fine university. We hope other cities will be encouraged by our success in routing King Alcohol, and "go and do likewise."

Redlands, Cal., Oct. 7. M. G. VAN LOAN.

Well done, my good friend. When cities of 12,000 inhabitants abandon the liquor-traffic we are certainly making headway. It seems that the good women of Redlands *did* have something to do with this. May God be praised for such victories. I think every time I visit California I have enjoyed seeing Redlands grow. When Mrs. Root and I were there, there were orange trees planted along the streets outside of the walk, and visitors were permitted to pick the fruit—at least that was the case on some of the streets.

GOD'S KINGDOM AND SATAN'S KINGDOM.

The *American Advance* as well as the *American Issue* is giving us abundant evidence of the coming of God's kingdom. See the following from the *Advance*:

Chancellor David Starr Jordan, of Stanford University, says, "The future city will no more allow an open saloon than the present city allows an open

cesspool. Every community has the same right to destroy its saloons that it has to kill its rats."

As an evidence, also, that Satan is pushing things, we submit below another clipping from the *Advance*:

"If the fight with prohibition goes to the last ditch, the great cities will be found aligned against the rural districts in a final struggle to eliminate the liquor traffic," declared Col. Jacob Ruppert, of New York, President of the United States Brewers' Association, at their annual convention at Atlantic City.

The launching of a national propaganda to fight prohibition in every stronghold was one of the chief topics thoroughly considered.

E. A. Faust, chairman of the Crop Improvement Committee, said:

"Within the next decade it is possible that the beer sales of the United States will reach 100,000,000 barrels annually."

MORE THAN HALF OUR TERRITORY AND MORE THAN HALF OF OUR PEOPLE NOW ON "DRY GROUND."

Out of the middle of a letter received from Wayne B. Wheeler, Superintendent of the Anti-saloon League, I clip the following:

"Seventy per cent of the territory of the United States is now dry, and nine States are dry. Forty-six million people live in dry territory, and a nationwide fight is on."

"CAN YOU AFFORD IT?"

I hate drunkenness; but I do not hate the drunkard.

If any man should have our friendship it is the man who has failed to be a friend to himself.

The fact is, the victim of strong drink often has all the virtues—including high intelligence and a tender, sympathetic heart—and yet when the demon Drink clutches him, his will is paralyzed and Satan is in the saddle.

A few weeks ago I visited San Quentin prison and talked with a man in the "Death Row" who has since been hanged.

"It was drink—just drink," he told me. "I was crazy. I was jealous, and I shot her. Then I shot myself. She died quickly. I recovered to be sent here. Next week I die. She was a beautiful, honest, loving wife to me, but drink had destroyed my reason."

I said nothing—what could I say? But I realized that the slow, lingering death of a drunkard's wife is no more tragic than the quick taking-off by knife or pistol.

The worst about strong drink has never been told. It can not be told—it escapes the limitations of language.

But I think we err in despising the drunkard. Our hearts should go out to him in pity.

A part of his hallucination often is that he is not a drunkard. "I can quit any time," he says. But he who says that seldom quits until death stops his mouth with dust.

"Wine is a mocker, strong drink is raging; and whosoever is deceived thereby is not wise." So said Solomon, a thousand years before Christ.

And the drink problem is upon us to-day, just as terrible, just as tragic, as it was then.—ELBERT HUBBARD, in *The May Cosmopolitan Magazine*.

Editorial

THE editor of this journal expects to attend the convention of the Ontario Beekeepers' Association, at Toronto, on Nov. 18, 19, and 20. See program in convention column. He also hopes to attend the New York State convention, Dec. 2 and 3, at Rochester; and, later on, the Iowa State meeting, Dec. 10, 11, and 12; at Des Moines.

DEATH OF I. R. GOOD, THE INTRODUCER OF THE GOOD CANDY FOR MAILING QUEEN-BEES.

SOME twenty-five or thirty years ago Mr. I. R. Good was more or less of a contributor to these columns. During this time he, like A. I. Root, was experimenting with new things. While A. I. R. was fussing with water-bottles so that queens could be sent by mail in connection with hard candy, I. R. Good was working in another direction—namely, that of making a soft moist candy which would not require the use of water; and it was so much of a success that it has been used clear up to the present time, and we may never find any thing any better. A. I. R. immediately dropped the hard-candy proposition and adopted the Good candy in his queen-cages. So successful was he with it that he became very enthusiastic about it at the time. Other queen-breeders adopted it until its use became almost universal; for Mr. Good was Good enough to give this valuable idea to the beekeeping world; and now that he has passed away we are in duty bound to recognize his contribution to the onward progress of bee culture in this country. It is proper to say, however, that Mr. Good was not, perhaps, the original discoverer of the method for making soft candy for bees. One Scholtz, of Europe, seems to have had a little priority; but Mr. Good should have the credit of introducing the candy into the United States. Mr. Scholtz, if he *was* the original discoverer, probably did not know the value of his discovery, while Mr. Good did, and immediately made it available to the beekeeping public of the United States. In so doing he conferred a great favor on his brother-beekeepers.

Mr. Good thought enough of his friend

A. I. Root and GLEANINGS to name his son Amos I. Mr. Good adds that his father "fell asleep in Jesus" on Sunday morning, Oct. 5 last.

OUR CARLOAD OF BEES ON THE WAY TO FLORIDA.

BEFORE this reaches our readers we shall have a carload of three hundred colonies on the way to Florida. One of our most experienced men will go with them, and we are going to try out the proposition of making the bees stay on the job ten months in the year instead of only five. Every Northern beekeeper knows that his capital—his bees, hives, and appliances—have to be idle in winter quarters anywhere from six to seven months in the year. This is not all. He will lose some, and all the colonies will dwindle in strength by next spring. It takes a lot of stores to build them up again. We are going to see if we can not cut down this idle time to one or two months, and make increase instead of a decrease.

We have changed our plan somewhat since our announcement in the last issue. Instead of building up the 300 to 300 *two-story* colonies for the production of extracted honey, and then splitting them up into 600 *one-story* colonies after the honey-flow, we are going to run them for increase, making the production of extracted honey secondary; that is to say, we shall extract just enough to give the queens room. We shall begin dividing in the midst of ti-ti; and when nectar from natural sources fails we shall keep up feeding.

Our apiarist, Mr. Ernest Marchant, was born and reared in that locality where he is going to take the bees. He was for years under the tutelage of his father, who is acknowledged to be one of the best bee-masters in the United States. A stranger could hardly go into that region and make a success of a venture of this kind. In fact, the same thing might be said of almost any locality with which a beeman is not familiar.

Mr. A. B. Marchant will operate further up the river; and after his honey crop has been secured, he will possibly be able to

furnish bees by the earload to Northern buyers. We bought two earloads of bees of him two years ago, and made a good thing of it, and there is no reason why others may not do the same.

OUR WATERWORKS APIARY; THOSE SWARMING
CARNIOLANS; THE ASPINWALL NON-
SWARMING HIVE.

THE front cover design for this issue shows our waterworks yard, located about 2½ miles northeast of the home apiary. In the background will be seen the Medina waterworks pumping station, and just in front of it one of our portable takedownable apiary sheds, one of which we use at each out-yard.

It was at this yard that we have been rearing Carniolans for the last two years, and where we had such incessant swarming in spite of all that we could do. The bees originally were run for individual comb-honey service, using shallow frames with foundation starters, top and bottom, as explained elsewhere in this issue. Of course this would have a tendency to incite swarming, and we were finally compelled to use drawn combs and extract.

In the middle of the back row will be seen a hive that is a little different from the rest. This is an Aspinwall non-swarming hive. Into this we put one of the strong Carniolan colonies that had been swarming so much. We naturally expected they would do it again, but they did not. No, they went right on storing comb honey, and did not swarm the rest of the season; and although the season was half over they filled some 70 odd sections with nice comb honey. Later in the season the slatted dividers became filled up with burr-combs. These we will show at another time.

It will be noticed that the two trees in the rear of the back row have the tops cut off. The reason for this will be better understood when we say that the Carniolan swarms had an exasperating fashion of going to the tops of those trees, some fifty or sixty feet high. Ye editor got so disgusted shinning up those trees that he finally secured permission to cut the tops off, with the result here shown.

The low shrubbery along the side of the road was also a favorite place for swarms. From there it was much easier to hive them; but in many cases they seemed to take a particular delight in settling on one of the posts of the wire fence where it was a slow and tedious operation to get them.

This is a good location because it is along the river; and during a period of drouth this yard will yield honey when the others may give only a scant supply. Down in

the flat, just back of the pumping-station, a good growth of sweet clover will be found, a picture of which we showed on the cover of our issue for Aug. 15th.

This yard, as will be seen, like all the rest of them, is located on one of our stone roads, so that at all times of the year or at any time of the day they can be easily reached by our motor truck, which will be seen in the background, just in front of one of the trees. This has been doing splendid service in reaching our yards during the past season. It not only carried men to and from the yards, but enabled us to have a central extracting plant at the home yard. It has brought home 20,000 lbs. of honey since the honey season was over, and it has been used almost daily to carry honey to Cleveland, where it is on sale at some of the principal groceries and drugstores.

GLEANINGS FOR 1914.

As announced on another page, we are planning another series of special numbers for 1914. The large number of post-card votes which we received from our readers indicated conclusively that the special-number feature is appreciated. The vote as it stands is practically unanimous.

We received many helpful suggestions for the future, which we hope may be the means of making the special numbers more valuable than ever. We wish that we might take up in one year all of the subjects that were suggested; but this would be impossible. We wish to take this occasion, however, to thank all of those who responded so promptly with their post-card votes, and who gave such practical suggestions. These ideas we shall bear in mind; and if it is the desire of our readers to have the plan continued for 1915 we will try to utilize more of the subjects mentioned at that time.

We believe our scheme for 1914 represents the wishes of the majority. Several of the numbers we should like to mention especially at this time. Much new material has developed along the line of the value of bees in orchards, and the fruit-men are awaking to the fact to such an extent that we believe the time will come very soon when beekeepers living in fruit districts need pay no rent for out-apiaries. It is our aim to have all of this new evidence, some of which is exceedingly valuable, brought together in one issue so that the beekeeper may have an opportunity of presenting the facts in concrete form to the fruit-grower.

There is always a call for material, especially for beginners. In our March 1st issue, "Beekeeping in Cities," we shall use considerable matter of interest especially to

beginners; for, although many beekeepers in cities are entirely out of the beginner class, there are enough others, just starting, to make the demand for elementary advice insistent.

In our April 1st issue we propose to get together the best material on "Breeding" that has ever been given to the public. It certainly is true that we know too little about selection of breeders and about breeding in general. There have been repeated calls for a special number on breeding, and at last we are able to arrange for such a number.

For our first number, January 1, we solicit interesting and practical articles from the poultry-raisers among our readers who have something worth while to make public. We are going to pay an extra price, as usual, for all material used in our special numbers, and this has reference as well, of course, to the material from our beekeepers who are also poultry-raisers. In this connection, however, we wish to say that all material intended for this Jan. 1st issue should be in our hands by Dec. 5. We shall be able to use some good clear pictures; but if possible we should like them by Dec. 1.

GLEANINGS is *your* bee-journal. It is your medium for expressing your ideas. While we have never yet known the time when we were short of copy, we are always anxious to get more and more of the very best material obtainable.

FILLING SECTIONS WITH DRAWN COMBS FOR
THE PRODUCTION OF COMB HONEY, AS
DESCRIBED BY J. E. HAND, PAGE 805.

On page 674, Oct. 1, Dr. G. A. Humpert, of St. Louis, describes his method of producing comb honey. It will be remembered that this was a scheme for producing comb honey in extracting-combs—that is to say, the combs were drawn out, filled with honey, and capped over, after which they were cut up in squares of a size that would just neatly fit inside of the sections. These squares, when inserted, were placed in the hive for the bees to fasten, after which they were ready for market.

Our ingenious friend and correspondent, Mr. J. E. Hand, of Birmingham, Ohio, has a plan somewhat similar, but differing in this respect: Squares of nearly drawn combs, before the bees have filled them, are put into sections. These are put into regular comb-honey supers, when the bees fasten them, fill them with honey, and cap them over. Mr. Hand describes this system in this issue on page 805.

He is entirely correct in saying that bees will accept and fill drawn combs when they will ignore foundation. He is correct also

in saying that, if we put drawn combs in sections in place of foundation the bees will enter them much more readily, and that we will secure a much larger percentage of No. 1 and fancy. But there is just one difficulty in the way, as we see it, and that is a serious one—to get a sufficient quantity of drawn comb to put into the sections in time for the honey-flow. To secure this it will be necessary to have a heavy flow, strong colonies, and probably shallow extracting-frames with thin super foundation; but thin super will stretch and buckle in frames as it will not in sections. Light brood foundation might overcome this; but then there would be danger of too much midrib.

For the last seven or eight years we have been experimenting with the proposition of getting the bees to draw out super foundation fastened in shallow frames, fill it with honey, and cap it over. Our problem has been nearly as great to get the bees to draw out thin super foundation in these shallow frames as to get them to accept the same foundation in sections. We have written Mr. Hand, stating that we thought there would be difficulty in getting the drawn combs; but he replied, saying that he has no fear on that score, because one good strong colony could furnish enough drawn comb to supply ten colonies having sections.

So far as we can ascertain, Mr. Hand has never tried this plan to any extent, or he might not be as enthusiastic about it. We have been trying something so similar, on a large scale, that we believe we have a right to an opinion on it. While it is easy to produce *extracted* in shallow frames containing drawn combs it is entirely another proposition to produce *comb* honey from foundation in shallow extracting-frames. We find that the bees are very slow about beginning this work in them. There must be a continuous and heavy honey-flow—precisely the same conditions we must have for the production of honey in sections. The bees will swarm nearly as much with one as they will in the other. We are becoming more and more convinced that the reason why bees hesitate to occupy a comb-honey super is not because it is cut up into little compartments or sections, as Mr. Hand implies, but because they do not like to stop and draw out foundation. If the sections are already filled with *drawn* combs, they will enter them just as readily as they do bait sections; but to get the drawn combs for *all* the sections—there's the rub.

Years ago, as Mr. Hand points out, we did produce artificial drawn comb by machinery. It was the work of the late E. B. Weed, and it was marvelously perfect. Bees accepted it as readily as they would

their own product; but every pound of drawn comb that we sold for a dollar cost us, we are convinced, anywhere from two to three dollars. The machinery was continually breaking down; and after we had spent several thousand dollars on the proposition we gave it up in disgust, more firmly convinced than ever that man would never be able to compete with bees in making comb.

There is another difficulty with Mr. Hand's system, and that is that the combs should be drawn the year they are put in the sections, not old combs of the year before. As Mr. Hand says, honey from unfinished sections is of inferior grade. Such sections serve the purpose of bait excellently, but further than that they are of but little use, and must be culled out and sold as seconds.

Mr. Hand has probably forgotten that Dr. Jesse Oren, years and years ago, tried out almost precisely the same scheme that he outlines in this issue. Why he abandoned it we do not know. About twenty years ago Mr. Barnett Taylor, of Minnesota, described a system very similar, with this difference: He saved out all the unfinished sections and extracted them. Then he had a little device that he called a "comb-leveler." This consisted of a hot plate slightly smaller than the inside of the section. An unfinished section was laid on top of this, and pushed down until the hot plate melted the comb to about half depth. The other side was treated in a like manner. Mr. Taylor found he could give his bees supers of these leveled-down combs in the sections, and the bees accepted them at once; but his plan was only a scheme to get rid of the unfinished sections. If we recollect correctly he soon abandoned it, as did all others. Dr. Jesse Oren and Mr. Taylor both sought to find some scheme whereby they could get the sections filled at top, bottom, and sides—hence the scheme of using drawn combs. But in later years Dr. Miller discovered a plan of using a bottom starter in connection with a nearly full sheet fastened to the top. This solved the problem of getting comb attachments to all four sides, and at the same time allowed the foundation to stretch downward as much as it would without buckling. This plan of two starters has proven so successful that it is now in almost universal use among comb-honey producers.

There is another difficulty with the drawn-comb proposition: When the bees start to draw them out they also start to fill them with nectar at the same time. They would have to be extracted, as the honey in them would not blend with the other after the bees got to storing in them again. Then the

liquid honey or nectar clinging to the sides of the cell would have to be licked up and cleaned by the bees. This would take considerable labor, both on the part of the bee-man and of the bees. When cleaned out they would have to be cut up and fitted into sections. This labor, if we are correct, would have to be performed in the midst of the honey-flow just at a time when the bee-man has no spare time at his disposal. On the other hand, when he uses foundation he can do all this work of filling the supers during the winter time or early spring when he is not busy.

As stated at the outset, we have been producing comb honey in extracting-frames for the last six or seven years; but this has been for the individual-service trade. It is not practicable to produce comb honey in sections $1\frac{1}{2}$ inches square; but there is a demand on the part of the fancy restaurant and Pullman-car trade which we have been supplying for pieces of comb honey $1\frac{1}{2}$ inches square. The only way to take care of this trade is to fill shallow extracting-frames with super foundation, using a bottom starter, and then get the bees to draw it out, fill it with honey, and cap it over. To do this requires nearly the same amount of skill that would be necessary in the production of honey in sections. Well, after we get the bees to draw it out and cap it over we are ready to cut it up into small squares, allow it to drain, and put it up in cartons. This we *know* is practical because we have been working it for seven years, and that very experience of seven years with this plan enables us to form some opinion of the plan described by our correspondent in this issue.

We do not wish to throw any cold water on the plan outlined by Mr. Hand. We should like to see it tried out; and if he or any one has been successful in any plan for the production of drawn combs from thin super foundation, so they can cut it up and insert it in sections, we shall be glad to have them tell us about it. There is no doubt that bees will occupy supers containing drawn combs far more readily than they will supers containing super foundation. And that is not all. The use of such drawn combs, as Mr. Hand says, either in sections or extracting-supers, will go a long way toward the control of swarming. We are convinced that one of the prime causes of swarming is *forcing* the bees to draw out comb foundation; and it does not make very much difference whether the foundation is in sections or in shallow extracting-frames. On this point our friend Mr. Hand may not agree with us. If wrong we shall be glad to be corrected.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

L. S. CRANSHAW made a plea for uniformity of terms, "colony," etc., *British Bee Journal*, 248. That warmed my heart. But before he got to the bottom of the column he was talking about managing 300 hives. O L. S.!

PARCEL POST has not been a success in sending honey, and there seems more or less of a feeling that it never will be. But across the water it has been in use successfully for years. Is there less enterprise here than in the old country?

No doubt you are right, Mr. Editor, p. 749, that wires will hold tender extracting-combs better than splints; and I doubt even whether running the splints into split top and bottom bars would make them better than wires. For all that, I think splints will give better combs.

RIGHT you are, Mr. Editor, when you say, p. 703, that unsealed honey sometimes may be ripe. It may be well to say that the converse is also true. Sealed honey sometimes may be unripe. I've taken off sections immediately upon being sealed that were the very finest and whitest in appearance, stored where other sections kept well, and they became dark and watery just because the bees had not ripened them sufficiently.

P. C. CHADWICK thinks the soil has no more influence on the color of nectar than the food he eats has upon the color of his blood. Are you dead certain, P. C., that your food has no effect on the color of your blood? Any way, I supposed it was the general belief that soil and elevation had an emphatic effect on qualities of nectar. Dr. Kramer says a change of soil makes a change of color in queens. A certain apple on the clay soil of my place is greenish, while two miles away on prairie soil it is red. If soil changes color in an apple, might it not also in nectar?

L. S. CRANSHAW says he has not found young queens laying as soon as ten days after the prime swarm, but usually expects a second swarm about that time—*British Bee Journal*, 248. I think Quinby's rule was that the prime swarm issues with the sealing of the first cell, and the second swarm about eight days after the prime swarm. But I've seen many a sealed cell where the bees had not yet swarmed. Per contra, I've known a prime swarm to issue with only eggs in queen-cells. But that was where the beekeeper had interfered by cutting out cells.

REV. G. H. CHATTERTON doesn't care for special numbers, because "It seems to confuse one when there are so many different views expressed," p. 702. There will be the same divergence of views, whether all in one number or scattered throughout the year, and I'd rather have them assembled in one number so they may be carefully compared as to locality, etc., instead of being more confused by indistinct remembrance of what has been in previous numbers. [Practically every one is asking to have special numbers for the ensuing year. We expect to have announcements out soon for a new list of subjects that we now believe will be attractive.—ED.]

MR. EDITOR, you have much to answer for, trying to stir up discontent in me. I've been quite content to stay north, summer and winter, and now that scheme of yours, p. 748, makes me feel I'd like to try North-and-South beekeeping. May be I'd better try it gradually, going a little way south this fall, say as far as Washington. [Say, doctor, what is the matter with your going a little further south than Washington? Just keep right on until you get to Jacksonville, Fla. A. I. Root will be glad to see you. Then shoot northwestward until you reach Apalachicola. You will see quite a wonderful bee country; but you should be prepared for mosquitoes. They are very fond of Yankees.—ED.]

MR. EDITOR, you must be trying to make me tear my hair and shriek with rage when you say, p. 705, "While you have been breeding toward non-swarmers, Mr. Burt has given his attention largely to honey-producers." Huh! just as if I cared nothing for honey-producers! Why, bless your heart, don't you know I've bent my whole energy toward breeding from best producers, even to the extent of breeding such vicious little demons as nearly drove every one off the place? Non-swarming came in only secondarily because favoring honey-production. And then to have you hint that I hadn't been giving "attention largely to honey-producers"! Just wait till you get my record for this year. [Beg your pardon, doctor; but if our occasional "breaks" on the even tenor of your way are the means of inducing you to bring out some new facts that you would not have done otherwise, our readers will be all the better pleased. Come on with your record. If it is a good one for a young man it must be all the better for one past his 82d year.—ED.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

A very little oil rubbed on the hands and knife when cleaning sections will prevent propolis from sticking, and save time and temper.

* * *

It is doubtful whether any thing so valuable has ever been written on the subject of the proper time to put on sections as the write-up by G. M. Doolittle, p. 521, Aug. 1.

* * *

On page 564, Aug. 15, in a paragraph on the pollination of alfalfa by the bees I read of the production of new varieties by the hybridization of colonies. It should read "clovers" instead of "colonies."

* * *

Editorial mention is made on page 558 of hive-tongs, and illustrations are given on pp. 573, 574, Aug. 15. But I have no use for tongs. I prefer to have hives with frames that are movable rather than to use an extra tool.

* * *

I am glad, Mr. Editor, that you could get out among the bees during the busy season this year. If there is any thing that gives a fellow new life and enthusiasm it is to "get out among the bees" when honey is coming in fast.

* * *

The caution given by A. H. Snowberger, page 579, Aug. 15, about hiving stray swarms on old combs is well worth remembering. There is certainly danger of foul brood if such swarms are hived on combs. Better give them three or four days in an empty hive.

* * *

That new method of introducing queens by smoke will be of great value if it proves as good when honey is scarce as it has when honey is abundant at Medina. A method that is simple and quick and which will succeed ninety-nine times in a hundred, at all seasons, is of great value.

* * *

On page 565 Mr. Chadwick tells how his bees have become accustomed to children. I am sure he is right, as I find bees are not nearly as "sassy" where they are brought up among folks. The most disagreeable bees I find in inspecting are those that have never been handled. Oh, my! but aren't some of them cross?

* * *

What is said in that paragraph by J. L. Byer, page 518, on the value of an abundance of old stores is not overdrawn. Every young beekeeper would do well to cut it out

and paste it on the door of his bee-house; and, better still, to practice it. I agree with Mr. Byer as to record-keeping. Very full records take too much time. I have found a board three or four feet long and five inches wide, with the numbers of the hives on it, ample to record all I wish.

* * *

I am glad to see Mr. Niver's name heading an article on page 576; and he makes a good point, too, on straining honey. I have tried several ways myself, but have not yet found any that was satisfactory but straining when hot through cotton cloth. The condition in which we often find extracted honey that we buy is not very satisfactory, with bits of wax, legs, and wings of bees, and sometimes larger portions of their anatomy.

* * *

On page 441 Mr. Chadwick refers to the fact in his experience of bees entering an eight-frame hive before they will a larger one. My experience has been the same; and it stands to reason that the same size of swarm will enter sections on an eight-frame hive before they will in a ten-frame hive; but there is another factor that comes in. A ten-frame hive is apt to have a larger store of honey, so that a colony in such a hive with abundant stores will breed up earlier; and, under such circumstances, it may even enter supers before colonies in smaller hives.

* * *

The editorial, page 516, mentions the cutting of sweet clover by the roadside. Yes, it is done almost everywhere. As one beekeeper said to me, "The farmers are fighting it;" and yet, as I have driven along the roads this summer, and have seen the stock trying to get their feed from the brown pastures parched with drouth, and then have noticed the rank growth of sweet clover beside the road, I have wondered how long it would be before the farmers would learn that a very much smaller area of sweet clover with its long deep tap-roots would furnish an abundance of feed for their stock during the long drouths we have almost every season.

* * *

UPPER ENTRANCE PROVIDED BY TIN TUBE.

On p. 599, Sept. 1, Dr. Miller says, "In America no one seems to think of a hive entrance anywhere except at the bottom, summer or winter." I believe, doctor, you are wrong, for I have used an upper entrance for many years on nearly all of my hives. I began using them so long ago that

I really can not tell how many years it has been, and I have found them so useful that I have put them in in nearly all my hives. I use double-walled hives almost exclusively, and I bore an inch hole through the outside case and packing and brood-chamber, and fit in a tin tube three or four inches long anywhere from four to six inches above the bottom-board. The bees seem to prefer it to the lower entrance, especially during early spring; but its chief value is in preventing the entrances from becoming clogged and dead bees from dropping to the bottom during long-continued cold weather in winter, for I winter out of doors.

* * *

SMALLER ENTRANCES AND AN ABSORBING CUSHION.

There has been considerable discussion in past years as to the best size of winter entrance for hives. Doubtless much will depend on circumstances, such as whether the bees are wintered in a warm or cold climate, out of doors, in a cellar, or damp or dry cellar; or if, out of doors, whether packed with an absorbing cushion above the winter cluster. I believe I have held the extreme view, that, where bees are wintered out of doors with a good absorbing cushion above them, a very small entrance is preferable. Last fall I closed a number of lower entrances, leaving only an entrance through a tin tube about $\frac{7}{8}$ inch in diameter. This tube going through the outside case, packing, and into the brood-chamber, I could not see in the spring that those colonies so treated had suffered in any way from lack of air or ventilation.

* * *

THINKING BEFORE ACTING.

Very entertaining reading, that story by J. L. Byer, page 531, about moving 250 colonies of bees 210 miles without a mishap! What interested me more than any thing else was the way he went at it, and it will bear repeating. He says, "The first thing to do was to formulate plans to carry out the work successfully. It is needless to say considerable study was spent on the matter for a few weeks prior to the trip." Exactly! and this accounts for his success. When I see how many people go into beekeeping and other lines of business without first planning their work I am not surprised at the failures which follow. One meets beekeepers with this or that style of hive or fixture, and inquires why they use it, and is informed it is because some one else does, or because some one has recommended it. They have never even asked themselves whether it is adapted to their wants or circumstances. Some beekeepers

use large hives where a smaller one would be better, or a small one where a large one would serve a better purpose, or frame hives where an old box hive or a nail-keg would do them quite as well. Some use Hoffman frames where propolis is so abundant that you need a crowbar to pry them apart, and a plain Langstroth frame, as he made them, would be vastly better. I hardly need add that the men and women who think and plan are the ones who will succeed in beekeeping. Those who find it too great an effort to think had better do something else.

* * *

RUNAWAY SWARM CARRIES FOUL BROOD.

Dr. Miller, page 633, Sept. 1, quotes D. W. H., "If a colony slightly affected with foul brood should cast a swarm, would the swarm, if placed on new frames and new hive, be liable to the disease if not exposed afterward?" Doctor M. says he doesn't know, and proceeds to do some fine guessing. May I throw a ray of light with my dark lantern? When visiting a beekeeper in the southern part of this State, who had about twenty colonies, I found among them two colonies with European foul brood and one with American foul brood. The colonies with European foul brood were easily accounted for, as some of his bees had had it before, and there was more or less in the neighborhood; but where could the colony with American foul brood have contracted the disease? It was a new colony, put into a new hive about three weeks previous, in the midst of a good flow of honey from buckwheat. At first I was puzzled as to the cause, and the owner also seemed exceedingly perplexed over the matter. If a new colony in a new hive should come down with disease in less than a month, what chance had he for keeping his bees free from disease? I began to ask, "Did you give this colony drawn combs?"

"No," he replied.

"Did you give this colony foundation in the frames?"

He said he put strips of foundation about three inches wide into each frame.

"Which old colony did this diseased colony come from?" I asked.

He did not know. He said he saw them first in the air, and had no idea where they came from. It seemed evident to me that the colony placed in this hive was a runaway swarm, and had come a long distance—it may be five miles or even more, and, passing near his yard of bees, and hearing them, had clustered. The foundation was quickly drawn out, and more or less of the honey brought with them had been stored and fed to young brood, causing disease.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

I have made an inspection of the eleven colonies of which I spoke in my last notes, in which I introduced Italian queens by the Miller plan. Out of the eleven I saved four, and the wings of two of them look as if they had been pretty well chewed up and the queens not overly active. No more experimenting for me for a while with new plans of introduction, at least until I am more able to afford the expense. Almost every one with whom I talk seems to think that this has been the worst season for years to introduce queens successfully. Even with the most careful painstaking, heavy loss has been sustained.

WHAT IS THE EFFECT OF FOREST FIRES?

This has been the most disastrous season for forest fires for years. Vast areas of choice ranges have been devastated in nearly all of the southern counties. Mr. M. H. Mendleson tells me that his famous Piru range was swept on one side of the canyon, burning up so close to his apiary that one colony of bees was destroyed. A clean yard is all that saved his hives from going up in the smoke. There is considerable speculation as to what extent a range is damaged by being burned off. One beekeeper told me a few years ago that he thought it improved a range to burn it off. I have been watching the results of burning over the ranges for several years, and I am thoroughly convinced that a range is not only injured but in many cases almost destroyed. Burning over a white-sage range does not injure it permanently, for new shoots spring up from the roots the following year, leaving it in almost as good a honey-producing condition as before. With the black sage it is different, for my observations have shown me that very little of it ever comes up from the roots, but must depend on reseeded. Mr. Mendleson tells me that in his locality it sprouts up from the roots, but that has not been the case in this part of the State. Seven years ago a vast acreage was burned over to the east of Moreno Road; and on the south side of San Mateo Canyon the fire was, I believe, in August, and made almost a complete sweep of the territory burned over. The winter following was a wet one, and the area was reseeded with black sage, which has grown to such an extent that it is now nearly the equal of its former days. Another area just to the south and west of my apiary was burned over a few years later. The winter following was a rather dry one, and the reseeded was

not nearly so complete. The range in that direction is permanently injured. This season is a very bad one for fires, for the seeding of the sages was very light in many places; and even if the winter should be a wet one there will not be an abundance of seed to reseed the territory properly.

WHAT IS A BETTER INVESTMENT THAN BEES?

It is no wonder that many of our beekeepers are discouraged, almost to the point of throwing up their hands in despair and quitting the bee business entirely. Two dry seasons in succession, and fires and black brood to contend with, make a combination hard to face. Are we fair to the little bee? I am afraid not. So long as the rains are abundant, the honey-flow regular, and the bees are healthy, we are great beekeepers, and prosperous fellows with plenty of courage and good cheer. But let a couple of dry seasons come along, the honey-flow slacken, and black brood make inroads in the vicinity, then down goes the mouth of almost every beekeeper. He complains of having to feed a few sacks of sugar to keep alive the same bees that have been helping to feed and clothe him. Now, Mr. Beekeeper, let us consider a few points. Suppose you sell your bees at a fair price, and quit the business. Where can you invest your money to better advantage? Where in California is there an industry that will return you as many dollars on the investment for ten years as beekeeping? It is not in the orange industry, the walnut industry, nor even the bean-growing industry. If you have, say, 500 colonies of bees, and sell them for \$7.00 per colony, you will have \$3500. How much bean land can you purchase for that sum? How many acres of oranges or walnuts? Wake up and figure a while. Things look blue ahead, to be sure, but no more so than in times gone by. Let's cheer up, face the music, get in, and feed the bees. Some of these days we shall have another period of wet winters, and all of this trouble will be forgotten when the extractor hums once more. Who knows but that it will be this winter? The present scourge of black brood will pass, and the fellow who stays on the job is the one who will win the reward, as sure as can be. The area of sage is narrowing down every year, and it will be but a few years until sage honey will sell at a premium. In fact, the day is now at hand when the beekeeper is going to exact the highest price for the best sage honey produced, in any quantities.

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

HEATING EXTRACTED HONEY.

The writer has had occasion during the last few weeks to reliquefy about 10,000 lbs. of honey, granulated more or less, and to make some observations in this connection. One of the greatest objections to heating extracted honey is the effect this has upon the color of the honey. Each successive heating will darken it a little more, if not carefully done; and if the honey is heated slightly too much the flavor will change also. It was found that slow heating of the honey, especially if it was in sixty-pound cans, and granulated solid, did not affect the color and the flavor as did rapid heating. In the former the honey was melted gradually and with very little fire. Rapid heating takes less time, but the results are less favorable.

A large vat was used, holding six sixty-pound square cans at a time. This vat is deep enough so that the cans can be completely submerged in the water. They rest on a framework of wood, so they are about two inches from the bottom of the vat, and the vat is about four inches deeper than the top of the cans as they stand in it. In order to supply heat to the top of the cans, which can not be done very well by the hot water, a cover is placed over the vat, and this holds in the hot steam. Thus the cans are all well surrounded by heat, and the liquidation is more even and is quicker.

At intervals the cover is removed and the honey in the cans stirred up if possible. Of course it is difficult to do this at first; however, we use a strong steel rod, about $\frac{3}{8}$ inch in thickness, and run this through the

mass of granulated honey at various places, so as to break up the compactness of the contents of each can. Doing this several times will enable some of the liquid honey to permeate through the cavities made, and hasten the melting of the honey. After that, the entire mass can be easily stirred, and the rest of the granulated masses of honey broken up, so that the liquefying takes less time, and none of the honey gets so hot as to spoil the color and flavor.

If a set of cans is started off in cold or only moderately warm water, and then heated carefully so that the water does not boil, there is little danger of spoiling the honey. On the other hand, with too much fire and the water boiling, there is a tendency in the honey next to the tin containers to become too hot before the granulated mass is entirely dissolved. This will occur in spite of stirring or breaking up the granulated masses as mentioned above, and care should be taken not to subject the honey to such high temperature. It is true that one can "work up" a large number of cans of granulated honey in a certain length of time; but there is no saving of fuel, and there is the risk of spoiling both color and flavor of the honey.

The vat method is mentioned here for the reason that most beekeepers must resort to that way of reliquefying their granulated honey. Usually the family wash-boiler is brought into play, and one can at a time is heated. This requires a lot of fuel unless the boiler is set into a furnace, and it takes quite a lot of time to heat any number of cans of honey. Another trouble is that these

boilers are not deep enough and do not permit subjecting the entire can to the heat. As a result the honey in the lower part of the can usually gets too hot while that on top is still in the granulated stage unless it is worked up continually.

A better method, and one which will pay any beekeeper, is to have a vat constructed of galvanized iron, to hold either two, four, or six cans, whichever is the most suitable for his use.

A furnace may easily be

Continued on page 820.

Scholl's honey-liquefying vat, holding six cans of honey. The new vat is deeper and has a cover over all to keep the heat around and over the cans.

Conversations with Doolittle

At Borodino, New York.

DOES LOCALITY MAKE THE DIFFERENCE?

"In GLEANINGS for October 1 the writer of Notes from Canada does not seem to agree with you regarding the rearing of bees with reference to the honey harvest. He apparently bases his ideas on 'our locality,' as he expresses it. But I, for one, have great faith in friend Byer, and wish that you would give some further information on the subject."

There certainly must be a difference in localities, for I note on p. 670, Oct. 1, that Mr. Byer says that it makes him hustle to get off his basswood honey before buckwheat comes on. In this locality, buckwheat is usually sown from the 4th to the 10th of July, and basswood usually begins to bloom from the 5th to the 10th of July. Except in long-drawn-out seasons, the flow from basswood lasts from ten days to two weeks.

In this locality Carniolans, Syrians, blacks, and most hybrid bees begin to breed to excess as soon as the harvest of white honey opens. Up to that time they do not have much more than half the brood that a ten-frame hive will accommodate. A good strain of Italian bees will have at the same time nearly, if not quite, the maximum amount of brood for the season. As the season advances they will still hold about the amount they had up to the middle of the harvest of white honey, when the queen will cease laying any longer at the outside of her circle of brood, confining herself to the cells vacated nearer the center. In this way we have little honey stored in the brood-combs till the last half of the nectar yield, and not then only as the brood has matured from the outside cells. The other races of bees keep on increasing their brood until the sides and ends of the hive are reached.

Many would have us believe that the sum and substance of beekeeping depends on keeping all queens employed at egg-laying to their fullest capacity. Queens, in any well-regulated apiary, are among the smallest part of the expense incurred. Labor, hives, and combs go toward making up the larger part of the expense. Bees, when they come on the stage of action at just the right time, are *very valuable*; but eggs are of no value only as they tend in the direction of producing these *valuable* bees required in the field at the time of the honey harvest. Eggs cost practically nothing; but as soon as the bees begin to perfect them toward other bees, then they begin to cost; and if this perfecting is going on to any great extent at a time when the perfected product

is placed on the stage of action, either before or after their presence in large numbers is needed, we not only have the cost of their rearing to pay for but the cost of the stores they consume afterward as well. A beekeeper willingly stands this expense at any time when the production of the individual bee is greater than its consumption. But I can see no object in doing this at any other time, simply that colonies may be "*always strong*," or that the *extra laying capacity* of any queen may be gratified.

Let me illustrate: Twice I tried the Syrian bees, and three times the Carniolans. In each case the bees would have brood to the amount of about three or four full Langstroth combs at the commencement of the white-honey flow, while the Italians had seven or eight frames full. By the middle of the flow the former would have brood in every one of the ten frames to the amount of about nine full combs, while the Italians would have the same amount as when the flow began. When the flow of white honey ceased, the Italians would have from 70 to 100 sections filled, and brood to the amount of five or six frames, or sufficient in both bees and honey for winter, if the fall flow-ers should fail. The others would begin to swarm near the close of the white harvest, and keep it up till ten days after the flow had ceased. Twenty poorly filled sections were the best I ever got from any of the five different lots tried; and, with one exception, all had to be given combs of sealed honey from the Italians to carry them through the winter. It took nine-tenths of all the honey these bees gathered to perfect these bees reared out of season.

If I had used duramies, as given in the article Mr. Byer objects to, confining those Syrian and Carniolan colonies to just what brood they did have, when the flow from clover and basswood began, they would have given the amount of honey consumed (by that extra worse-than-useless brood reared) in the sections, and I would have had something to show for my labor, but nothing like that given by the Italians.

Now, as I have said many times before, let each know his locality and govern himself accordingly. If colonies "always strong" do best in a certain locality, that is what one should work for; but from my multitudinous correspondence through the last forty years I know that the rearing of bees with an eye to the harvest "draws the prize" in more localities than in Central New York.

General Correspondence

A NOVEL WAY TO PACK COMB HONEY FOR MARKET

Producing and Shipping Comb Honey in Shallow Frames

BY J. J. WILDER

There are many advantages in producing comb honey in frames rather than one-pound sections. Much more can be produced per colony with less manipulation, and at the same time it can be sent to market as safely, and net the producer as much per pound as comb honey in sections.

The illustration shows the package and manner of packing which I have adopted. I have found it perfectly satisfactory and very economical.

The box is made of very strong pasteboard, with soft partitions to separate the frames of honey. These are set in the case loosely as the frames of honey are put in, and are about $\frac{1}{4}$ inch higher than the frames, so as to keep all weight off the frames.

The box consists of only one piece of pasteboard, and, when set up, makes a complete box with bottom and top. There is a strong soft pad which is placed on the bottom, upon which the frames rest. There is also a pad placed on top of the frames. Then the top of the box is folded down and well wrapped with binder's twine. The boxes are made to hold eight frames. These, with the partitions, completely fill the box and pre-

vent the frames from shaking about, either from the sides or ends. The twine, drawn tightly around them from both ways, braces the boxes and makes them very strong. They will stand much rough handling. The frames should be well filled and of nearly even surface in order to pack to good advantage. The top-bars are cut off even with the end-bars so as to give a good bearing at the end of the cases, and the end-bars will keep the honey properly spaced, and there is but little chance for the surface of the honey to become crushed or broken. Of course the frames should be well cleaned up. It is a very easy matter to get the net or gross weight of each package.

Honey thus packed is readily sold on any market, and will reach the consumer in good condition. Dealers who buy up and repack honey for the trade find it the very best.

Cordele, Ga.

PUTTING FULL SHEETS OF FOUNDATION IN BROOD OR EXTRACTING-FRAMES

How to Use the Groove-and-wedge Plan for Securing the Foundation to the Top-bar; Preventing Sagging and Buckling

BY H. H. ROOT

There have been innumerable plans suggested for wiring frames. Elaborate forms have been illustrated in these columns for clamping the frames, holding the spool of wire, etc. We have tried many of these, but

Comb honey marketed in the shallow frames in which it is produced. On account of the danger of breakage of the large combs, the frames are separated by soft pads, and all packed in a corrugated-paper shipping-case.

FIG 1

FIG 2

FIG 3

FIG. 1.—Dropping the sheet of foundation into the groove. The imbedding-tool, also shown, being heated over the lamp. FIG. 2.—Inserting the wedge. FIG. 3.—Sinking the wedge into the groove. End of stick used is shown at A.

we prefer our two hands, a pair of pliers, and a board the right length to wind the wire on. However, this is another story. There have also been all sorts of plans suggested for wiring — horizontal, vertical, crosswise, combinations of one, two, or all three, etc. But I propose in this article to give a simple plan of putting full sheets of foundation in frames having four horizontal wires in such a way that the resulting combs are as straight and free from sagging as it is possible to expect.

The plan suggested by Mr. A. B. Anthony, of Sterling, Ill., reported editorially in our August

The hot teeth melt a small portion of the wax, firmly "cementing" the wire in place in the center of the foundation.

15th issue, last year, is one that has a great deal of merit, for it certainly results in beautiful combs. It is not an easy matter to imbed wires out of line, however, and very likely this is the reason why more beekeepers have not followed the plan. I hope that the description and the photographs reproduced herewith may help many to secure perfect combs—combs which do not have a lot of drone-cells near the top-bar, and which are not bulged out of shape. The ideal way to imbed wires in foundation is by means of electricity; but owing to the difficulty in obtaining the right kind of current, this plan is out of the question for

the great majority. The regular tools ordinarily used for imbedding the wire simply push the wires into the wax, but do not firmly secure it where it belongs, and on this account the foundation is likely to swing away from the wire, so that the combs when built are crooked, or else the wires are to one side of the midrib. Using a hot imbedding-tool overcomes this difficulty, for a very little wax is melted at each point where the tooth strikes the wire, so that the wire is firmly cemented in place. Thus it is not necessary to run a stream of wax over the wires afterward, for they will not pull out unless the foundation is torn to pieces.

Shape of tool used. The broad blunt teeth do not cut the foundation, thereby weakening it, even if the tool is used cold. If used hot each tooth melts a small amount of wax, firmly "cementing" the wire in place.

Looking through a finished frame, showing how the wires are deflected out of line.

DIKECTIONS FOR PUTTING FULL SHEETS OF
COMB FOUNDATION IN WIRED FRAMES,
AND IMBEDDING THE WIRE IN THE
WAX.

In order to do rapid work in putting foundation in frames, select a bench or table large enough to hold the empty frames, the pile of foundation, imbedding-tool, etc. Prepare the following equipment: A common kerosene or coal-oil lamp (one having a metal chimney preferred), a small box the same height as the lamp, and a board about one inch thick, of such a size that, when laid flat on the bench, the frame will just slip over it, in which position it will be supported only by the wires resting on the inch board. Light the lamp, being careful not to have the wick turned very high. Place it on the bench and move the box above referred to close to it. Put the imbedding-tool over the lamp, resting the metal part on the edge of the chimney so the spur wheel will come directly over the heat. Support the handle by means of the box. Fig. 1A.

Select a wired frame; turn it upside down on the bench so that it rests on the top-bar. There are two grooves in the top-bar, the one nearest the center for the foundation, and the other one for the wedge. The frame should be standing on the bench with the groove for the wedge toward you. Pick up a sheet of foundation from the pile, being careful not to wrinkle the edge, and place it in position in the frame, holding it with the two hands, as shown in Fig. 1, the fingers reaching around the end-bar on to the other side of the foundation. Start one corner into the center groove, and then, by

pulling slightly with the other hand to straighten out the sheet, and at the same time giving the frame a slight jar on the bench, the foundation will settle down into the groove. Make sure that it is down as far as it will go, so that the vertical edges are parallel with the end-bars of the frames. Start one end of a wedge in the groove, taking pains to have the beveled side next the groove containing the foundation. After the wedge is started in the groove at the left end, draw your right hand along, thus pressing it down as much as possible. Then take a stick three-quarters of an inch square, the end of which is notched as shown in Fig. 3A, and, starting at the left end of the wedge, push it down below the top of the groove. Move the stick rapidly along the groove toward the right, pushing down about every two inches so that the wedge is pushed clear down below the top of the groove all along. If this is not done, the wedge is likely to drop out later on when the wood shrinks, thus allowing the foundation to fall out when the bees get on it. The notched stick referred to should be cut with a saw from hard wood, and the shorter projection should not be over an eighth of an inch long, so that, when the stick is pushed down, the wedge will be pushed in a sixteenth of an inch below the top of the groove.

Lay the frame, in which the foundation is fastened, over the inch board, letting the foundation be next to the board and the wires on top. Push down on each end-bar to make sure that the foundation lies flat on the board. If you are right-handed, stand

at the right end of the frame; take the hot imbedding-tool in your right hand, and, beginning at the left-hand end of the frame, which is the end furthest from you, draw the notched wheel along the wire toward you, going from one wire to another until all are imbedded. Press on the handle of the tool just enough to imbed the wire about half through the foundation. The hot teeth melt the wax at each point they strike, thus holding the wire in place. Fig. 4. Do not draw the tool too rapidly nor too slowly. After trying two or three frames you will easily catch on to the knack, so that you can do rapid work. The tool should not be so hot that it melts too much wax, nor so cool that it does not melt the wax at all. When you first begin, the wheel may stick slightly so that the teeth have a tendency to slide along the wire; but as soon as the melted wax covers the bearing, so that it is thoroughly lubricated, the wheel will work freely.

TO PREVENT SAGGING AND BUCKLING.

To overcome the tendency of the foundation to sag and buckle out of shape after it is put in the hive, imbed the first wire—that is, the one nearest the top-bar, with what sag there is below the horizontal. The next wire should curve down also, although not as much as the first one.

Imbedding the wires with a hot spur wire-imbedder. The upper wire is pulled down out of line toward the bottom-bar. The next wire is also pulled down, though not so much. The third wire is left straight. The lower wire is pulled up toward the top-bar.

On July 23 was held a bee picnic at Gayville, S. D. It was well attended, and some of the vital questions pertaining to apiculture were discussed, such as "Bee Diseases," by L. A. Syverud, of Canton, bee inspector for the eastern part of South Dakota; "Relation of Bees to Plant Life," by R. A. Morgan; "The Production of Comb Honey," by J. J. Duffack, of Yankton; "Preparing Honey for Market," by W. P. Southworth, of Sioux City, Iowa.

The third wire should be about straight. The fourth, or lower wire, should have all the slack taken up by a decided curve toward the top-bar. Fig. 6. The upper wires prevent stretching of the upper part of the foundation, thus reducing the tendency on the part of the bees to build drone-cells near the top-bars; and what little sag there is will not cause the lower half of the foundation to buckle, since the lower wires can move down with it to some extent.

The wires can be more rapidly imbedded if they are left straight; but with a little practice it does not take much longer to imbed them when they are curved, as above mentioned. To facilitate the work, cut a piece of tin three-quarters of an inch wide and about eight inches long. With a pair of shears taper one end down to about an eighth of an inch in width. With a pair of pliers make a sharp right-angle bend one-sixteenth of an inch from the end of the tin, thus making a very small hook. Holding this tin hook in the left hand (Fig. 7), pull the upper wire down toward the bottom-bar, letting the tin lie flat on the wax. The imbedding-tool will pass over it without the least difficulty. Hold the tin for an instant after the wire is bedded until the wax sets, then go to the next wire as in Fig. 8; but it is not necessary to pull this one down quite as far. The third wire (Fig. 9) may

be imbedded just as it lies in a straight line. The fourth wire, that is, the lower one, should be pulled up toward the top-bar, as in Fig. 10. In case the foundation is not given to the bees at once, the wires should not be drawn out of line quite as far, owing to the fact that the two upper wires might then draw it up too much, thus causing a wrinkle.

The imbedding-tool will remain hot for all four wires. It should then be placed over the lamp to keep up the right amount of heat for the next frame. If too much wax accumulates on the imbedding-tool shake off the surplus occasionally on to a piece of paper. The surplus wax, however, does no real harm unless it accumulates to such an extent as to drop down the lamp chimney and cause it to smoke.

SMOKE METHOD IN DIRECT INTRODUCING FURTHER INDORSED

BY J. E. MARCHANT

Nov. 1, p. 768, Mr. J. C. Mosgrove says he is not in favor of using smoke when running in queens. Mr. Mosgrove, did you ever give it a trial? Don't condemn this method until you have given it a fair test. Your reason is, if it is at a time when there is a dearth of honey the colony will be demor-

alized to such an extent that it falls an easy victim to robbers, or the smoke may cause the bees to fall upon the queen and kill her. It isn't necessary to get robbing started by performing such a simple operation as smoking in a queen. *We want the bees demoralized.* That is why we use smoke; that is where the success of introducing comes in.

If you have certain favorable conditions to introduce queens by the method you have been using, you get good results. By the smoke method, I get perfect results under almost any conditions. Even laying workers will accept a queen. You can run a queen into a colony that already has a queen by smoke, and the bees will kill the old queen, and accept the newly smoked-in queen.

Only yesterday, Oct. 27, one of my friends, a beekeeper, said, "Marchant, that smoke plan of introducing is the greatest plan on earth to introduce a queen. You remember that old virgin you gave me? Well, I smoked her into a colony that had laying workers which had refused to accept a laying queen that was given them with lots of her young bees. They accepted the virgin all right. I saw her an hour after smoking her in, and also two weeks after. But, unfortunately, the weather was so bad she could not get out to mate; so I killed her and smoked in a laying queen, which is doing well."

I conscientiously recommend the smoke method to beginners and amateurs. By introducing by this method, which I use entirely, one will succeed 95 times in 100 under almost any conditions.

Medina, Ohio.

NEW PRINCIPLES IN SECTION-HONEY PRODUCTION

BY J. E. HAND

Section-honey producers have long recognized the fact that bees have a decided antipathy against beginning work in sections, even when full sheets of foundation are given. This trait is so strong in some colonies that they will sulk and loaf, and actually refuse to enter sections, until compelled to do so by force of numbers. This is not to be wondered at when we consider that the space in section supers is chopped up into ridiculously small divisions, and interspersed with and intersected with pieces of wood in the form of separators, and the vertical sides of sections.

This abnormal condition breaks up the cluster, interferes with their method of ventilation, and breeds discontent among the bees, which is quite likely to result in ex-

sive swarming since it is during this period of enforced idleness that the swarming fever is usually contracted. When once contracted, the fever will usually run its allotted course. While we may, by curtailing their efforts and frustrating their plans, discourage swarming, the chances are even that we have likewise discouraged honey production, lost control of our bees psychologically, and, therefore, made serious inroads upon our crop. For a condition of discontent among bees is not conducive to best results in honey production.

A NECESSARY EVIL AND A SUGGESTED REMEDY.

Since the abnormal conditions just described are imperative, and can not well be dispensed with in the successful production of section honey, a powerful influence must be exercised over the bees in order to overcome their antipathy against existing conditions within the storing-chamber, as well as an incentive so powerful as to induce them to enter the sections readily and eagerly.

It is well known that empty combs are a great incentive to induce bees to begin work in supers; hence they will enter extracting-supers more readily, and swarm less than with section supers when full sheets of foundation are given. Many have profited by this eccentricity by using bait sections filled with partly drawn combs carried over from the previous season, while others use an empty extracting-comb on each side. The objections to this plan, as we see it, are, first, the harvesting of two different products in the same super introduces undesirable complications, and occupies room that should be devoted to comb-honey production, especially since select colonies are usually chosen for this purpose. Second, it does not overcome the antipathy of bees against drawing out foundation. Concerning bait sections, while they evidently have some influence in inducing bees to enter sections, the incentive is not strong enough to outweigh their antipathies; hence it occasionally happens that the bait sections are the only ones in the super that are finished. In this case the others present a forlorn and dilapidated appearance as the result of an attempt on the part of the bees to remove the foundation as so much waste matter. This fact, coupled with the knowledge that fancy and No. 1 honey are seldom found in bait sections, is sufficient to prohibit their use. After testing each of these methods in turn, we discarded them both as being inefficient, ineffective, and totally inadequate to our needs.

ON THE RIGHT TRACK.

Being thus thrown upon our own resources we began to cast about to discover some method that would enable us to over-

Apiary of T. Stapleton, Gwinear, Hayle, England. he uses strictly up-to-date hives and fixtures.

Mr. Stapleton also has an outyard. In both apiaries

come these seemingly insurmountable obstacles. At this stage, however, the bee journals were discussing, pro and con, the advantages of using full sheets of partly drawn comb in all the sections. Though convinced of the soundness of the theory, we were no nearer the coveted goal, for want of a practical method of securing these combs and fitting them into sections. At this time, however, the Root Co. being, as usual, awake to the needs of the hour, were experimenting with machinery for the manufacture of partly drawn combs, of a size to fill completely a $4\frac{1}{4}$ section.

THE PROOF OF THE PUDDING.

After securing a sample, and finding it entirely satisfactory, we immediately ordered enough to fill 2000 sections; and having lost no time in putting them on the hives we anxiously awaited results. We did not have long to wait, however, for the bees immediately took possession, and the eagerness with which they began work in those sections was indeed a revelation to us. These sections were filled rapidly, and were the finest we had ever before seen; furthermore, swarming was reduced 50 per cent, with a marked increase in the average production per colony. The proof of the pudding convinced us of the value of drawn combs in sections, and we would gladly have paid \$1.00 per lb. for it the following season; but, unfortunately, its manufacture on a

large scale was not a success, and it was not to be had at any price.

BEATING ROUND THE BUSH.

Again thrown backward upon our own resources, we scarcely knew which way to turn; but realizing the advantages of having combs firmly attached to the wood on all sides of sections, we were induced to give Dr. Miller's two-piece method of filling sections with foundation a trial. After using full sheets of drawn comb with such surprising results, however, it was a long step backward to cut up foundation into small pieces, and handle and rehandle the sections, one at a time, over a hot plate, not mentioning those that drop down from the weight of bees because the plate is either too hot or too cold. And, finally, we discarded this method also, as being altogether too primitive and antiquated to meet the exigencies of progressive methods. Necessity is the mother of invention, and again we began to cast about to devise some up-to-date method for the perfect filling of sections with foundation. This movement resulted in the development of the split-section idea, by means of which we were enabled to place a continuous sheet of foundation in the center of four sections at one operation without removing them from the frame, and the sections were so perfectly filled that no crack was visible. This was a decided improvement over former methods,

and resulted in a high percentage of fancy honey in the finished product.

PSYCHIC CONDITIONS AN IMPORTANT FACTOR.

Notwithstanding this, however, we were painfully reminded of the antipathy of the bees against existing conditions within the supers; for swarming became the rule instead of the exception, to the extent that we were compelled to devise a special equipment for the control of it. This led to the development of the switch method of controlling bees by mechanical means, which settled the swarming question in short order. It soon became apparent, however, that we were not getting the best work out of our bees that they were capable of performing; for while we had almost perfect control of swarming it was a matter of forcing them into the sections by sheer force of numbers, regardless of their inclination.

Since bee nature still revolted against the abnormal conditions that still existed within the storing-chamber, there was considerable loafing; and it became evident that the forcing process was not conducive to best results in honey production; therefore if we would maintain the psychological condition of contentment and satisfaction that is essential to best results in honey production, we must furnish an incentive so powerful as to overcome all their idiosyncrasies, and induce them to enter sections willingly and eagerly.

NEARING THE GOAL.

Fully realizing that, next to combs of brood, freshly drawn combs are the most powerful incentive imaginable to induce bees to enter supers, we soon developed our split-section idea into a method that enabled us to take a strip of drawn comb from the hive, and, while still warm, place it exactly in the center of four sections, without loosening it from the frame or touching it with the fingers, or using any tools of any kind. To say that we were enthusiastic about the development of the principle is putting it mildly; for we felt like throwing up our hat and shouting "Eureka!"

COMING DOWN A PEG.

But, alas for human endeavor! "the best-laid plans of mice and men gang aft aglee," and we were not the exception to the rule, for unforeseen and unexpected complications arose, and apparently insurmountable obstacles blocked our pathway to success along the line of split sections; and it became painfully evident that we had chosen the wrong method of applying the principle. Our disappointment was lessened by the knowledge that certain features of the split-section method had always been a thorn in the flesh to us, and we consoled ourselves

with the belief that we had about outgrown the idea.

THE GOAL ATTAINED, AND THREE PROBLEMS SOLVED.

The knowledge that the basic principle must ever remain unchanged until the nature of bees is perverted was a consolation, and we cheerfully and hopefully began to bestir ourselves to discover the correct method of applying it. It involved a little inventive genius, however, for our mind naturally reverted back to our hitherto unprecedented success with the little squares of artificial comb, and little time or talent was required to develop the principle, for we felt assured that we had at last discovered the correct method of doing it, and subsequent events only strengthened the conviction.

THE EQUIPMENT.

No extra equipment is required in practicing this method, except a form composed of four blocks of wood nailed to a thin board. The position of the blocks when nailed in place is such that they will fit loosely into the four sections when the frame holding them is placed upon the form. The thickness of the blocks is governed by the thickness of the section and the depth of cells in the drawn combs. A gauge is used for cutting up the comb into pieces of a size to fill completely and snugly the sections. Two sharp thin-bladed knives are needed; for if the cells are very deep it may be necessary to use a heated knife in order to do a smooth job.

HIVES AND SUPERS.

Any standard hive of the Langstroth dimensions is adapted for use with this method. Concerning supers, any of the standard brands may be used without modification. In my opinion, however, the one listed in the Root catalog and designated as "N," Fig. 707, is best suited for this method, since it is provided with section frames which protect the outside of sections, keeping them neat and clean. It also admits of handling four sections at a time over the form; furthermore, it admits of either comb or extracted honey production, or both together, by simply changing frames. With this method it is not advisable to use extracting-combs on the sides, but, instead, a half-inch space back of the outside separators. This will insure a better filling of the sections in the outside rows.

UTILIZING WASTE MATERIAL.

A sufficient number of extra-strong colonies should be selected for the purpose of drawing out foundation in connection with extracted-honey production. In this way the labor involved in the operation does not

materially interfere with the legitimate occupation of extracted-honey production, since this labor is usually performed by young bees that have not yet become field laborers. Viewing it thus, it is evident that by this process drawn combs are secured practically free of cost, since the spontaneous secretion of wax by such a colony would otherwise be carried out between the mandibles of the fielders, and dumped as waste matter; hence economy in the utilizing of waste material is a strong point in the development of this system. By keeping the super next to the brood-chamber constantly supplied with sheets of thin foundation in shallow frames, and the top one constantly supplied with empty extracting-combs, swarming is held in check, and a surprisingly large number of drawn combs may be secured per week without materially lessening the honey crop.

THE SYSTEM CONSIDERED.

While the development of the new system is fraught with rich promises of ultimate success along the line of the spontaneous control of swarming, there are other important factors to be considered in this connection besides the building of comb; and whether or not the psychic condition of the bees, resulting from the application of scientific principles, will be of such a nature as completely to overbalance abnormal conditions within the supers, and ultimately result in the spontaneous prevention of swarming, is a matter yet to be determined, since failing health, during the last two seasons, has prevented further experimenting along this line. Viewing it thus we do not feel competent to forecast ultimate results along this line.

Drops of nectar will usually be visible in the bottoms of cells when about $\frac{3}{8}$ inch deep. If left much longer, sufficient nectar will have accumulated to necessitate throwing it out with an extractor; in which case it may be fed back, but not to the finishers, since it would undoubtedly counteract the influence against swarming. This, however, is a matter that has not yet been fully determined for reasons just mentioned. A little experience, however, will enable the beekeeper to adjust the matter of depth of cells to suit the exigencies of the case. Undoubtedly the possibilities of section-honey production and swarm control along psychological lines, a condition of soul satisfaction and content as applied to bees, are at present beyond the control of the average beekeeper.

THE MODUS OPERANDI.

In view of the crude and rambling manner in which the details of the method have

been discussed, it seems like a repetition to outline the mode of operation. Having the sections folded, placed in frames, and corded up within easy reach, and the squares of drawn comb cut to the right size, place a frame containing sections over the form; place a block of drawn comb in each section, gently placing it in a correct position by means of a follower of equal longitudinal dimensions, and secure it by means of melted wax mixed with a little rosin, and applied with a brush around the edges of the comb. A little practice and experience will enable one to operate rapidly and neatly, and with results that will be highly gratifying.

OUR CLAIM.

We claim for this method, first, perfect control of bees along psychological lines; second, control of swarming—if not spontaneously, at least by means of a simple equipment; third, an increased production per colony of 50 to 100 per cent; fourth, a higher percentage of honey in the fancy grade; fifth, safe transportation by freight, since the combs are built solid to the wood on all sides; sixth, a perfect section of honey, practically free from pop-holes; seventh, it protects the outside of sections, keeping them clean and neat; eighth, it admits of handling four sections at a time over the form; ninth, sections are filled with combs without removing them from frames; tenth, it minimizes expense by utilizing waste material in comb-building; eleventh, it minimizes expense for equipment, and is rapid in operation and positive in results.

Birmingham, Ohio.

DEMONSTRATION ON HANDLING BEES GIVEN TO CLASS IN AGRICULTURE

BY ARTHUR RHODES

The picture shows the agriculture class from the Langston Agricultural and Normal University for the colored people of Oklahoma.

These young men had never taken up the study of bees, and I invited the professor and students of the agriculture class to come to my home, where I gave them a lecture and demonstration on handling bees. The class was very enthusiastic on the subject of bees, and a number of them said that they were going to take up the study when they returned to their homes in different parts of the State.

I gave a lecture to the children of our public school last fall, and offered a prize for the best essay on the subject. There were 12 papers submitted, which were very good. The papers were graded, and a prize

Colored students from the Langston Agricultural and Normal University taking a lesson on bees.

was awarded by the State President, Mr. N. Fred Gardner, of Geary, Okla.

With the increased acreage of alfalfa, sweet clover, and cotton, Oklahoma will be one of the leading honey-producing States of the Union.

BEEKEEPING IN NEW ZEALAND

Some of the American Methods a Failure Due to the Difference in Locality

BY C. A. OLDMAN

Naturally I thought I was on a fairly safe wicket by following the plans of management given by such prominent beekeepers as Dr. Miller, Alexander, Doolittle, and others; but expensive experience has proved otherwise, and now I can agree with Hutchinson that "The question of all questions is that of locality."

In short, I find by experience that, if one would be successful in beekeeping, locality must first be studied thoroughly, and then any desirable plans modified to conform to the conditions that locality enforces. Weather conditions in the same locality vary, and a plan that works to perfection in a normal year will require modifying to suit unusual seasons. For instance, four seasons ago shaken swarming on foundation was a perfect success, the season being a fairly nor-

mal one, and the weather warm; but the last three seasons it has been far from successful, owing chiefly to very changeable weather, and I had to give a frame of brood and two or more drawn combs (the rest being foundation) when shaking, or I found that no attempt was made to begin operations in the brood-chamber. An excluder was used in every instance.

The plan of placing the shaken brood-chamber to one side in order to allow brood to hatch out also had to be modified, and I practiced putting it on top of a colony that could use the extra bees, giving the shaken swarm a brood-chamber from another shaken colony later on, if they required it, when their own brood-chamber was well advanced. I have had too many cases of maturing brood perishing, owing to cold changeable weather, and I have no intention of again leaving brood-chambers to care for themselves, as I consider it far better to be sure than sorry.

Alexander's plan for increase proved a dismal failure, so far as I was concerned last season. I tried it rather extensively, with the result that I materially reduced my prospective honey crop. Most colonies treated made no attempt to start a brood-chamber and the majority of them started cells on the frame of brood given below, and superseded their queens even though their queens were young and had proved to be first-class before the change was made. It

Exhibit of honey and fixtures at the Madison County Centennial, September, 1912.

is only fair to add, however, that last season was a very peculiar one, and very cold wintry weather alternated with nice summer weather, so it is fairly safe to blame the weather rather than the plan for the failure.

I intend to give this plan another trial this coming season, but will use wire cloth instead of the excluder under the shaken brood-chamber on top of the hive, and thus force the shaken bees to remain below with the queen.

I also intend to try the wire-cloth plan for treating any cases of foul brood I may have. I will treat them practically the same as outlined by W. W. Case in *GLEANINGS*, June 5, 1913, p. 406, with the exception that I will fasten wire cloth under the old brood-chamber and place it on top of the new hive, using an escape for the bees to leave the old combs and find the lower entrance. My reason for doing this is to give the maturing brood the benefit of the warmth rising from the cluster in the hive below, and to avoid all risk of chilled brood by a sudden cold change. If this plan proves successful it would do away with all risk of combs melting down from want of ventilation during hot weather.

In regard to the swarming problem, I would say that our season here extends for six or seven months, and the plans that work well in preventing swarming in the short seasons in most parts of America are hardly suitable here unless, perhaps, they were used repeatedly. I have just about decided that it pays me best to allow prime swarms to issue naturally, or to practice shaken swarming (keeping the queens clipped, of course), and hive on the old stand,

shaking all bees from the brood-combs along with the swarm, and giving the old brood-chamber to a weak colony as a super.

I use excluders on all colonies, and produce chiefly extracted honey.

My purpose in writing this letter is certainly not to decry the plans and suggestions of experienced beekeepers in America, but rather to give a warning to beginners in various climates to go easy with any plan they may fancy, and avoid paying too dearly for their experience. A beginner is very apt to jump to the conclusion that, if prominent beekeepers' plans work well in his own locality, they are bound to be successful in every locality. This false idea can not be corrected too often.

Canterbury, New Zealand.

HONEY DISPLAY AT THE MADISON COUNTY CENTENNIAL

BY LOUIS WERNER

The honey display shown in the illustration was made at our Madison County Centennial, Sept. 14 to 21, 1912. The celebration was like a street fair. There were exhibits of cattle, poultry, and farm produce, as well as old-fashioned relics 100 years old. They said, of course, we must have our bee-man make an exhibit.

The display was 16 feet long, 8 feet high, and contained comb and extracted honey, live bees, one full colony, two one-frame nuclei, and comb foundation. All the fixtures that are used in a first-class apiary were shown. Everybody thought it was the best exhibit on the centennial grounds. This

display contained 300 lbs. of honey, ranging from the smallest section to the full extracting-frame shown on the upper shelf in the center. I was awarded eight blue ribbons as first premium.

In 1886 my apiary consisted of 90 colonies which increased to 140. This yard produced 7000 lbs. of comb honey, nearly all of which was salable. White-clover pasture at that time was better than now. I got the bee fever, and the only remedy at that time was more bees. The first thing I knew I was overstocking. I soon had an apiary of 300 colonies. Finally I contracted rheumatism, and had to reduce my apiary to a smaller number of colonies; but the bees were of better quality. I handle nearly all of my bees without a veil. The best bees I have found are a cross between the Italian and Carniolan or Caucasian bees. They are good workers, winter well, are easy to handle, and they do not swarm any more than the pure Italians. I have tried them all.

Edwardsville, Ill.

BEE INSPECTION IN MONTEZUMA CO., COLO.

BY MRS. GEORGE TAYLOR

Since Mrs. H. M. Barber died (about ten years ago) Montezuma County has had no bee inspector, and it is remarkable how rapidly conditions change for the worse. Last spring the beekeepers became alarmed as to the outcome, so they got a petition before the county commissioners, asking for an appropriation to carry on inspection. The commissioners were indifferent, but, nevertheless, allowed \$200 to carry on the work. The next step was to get into communication with our State Inspector, Wesley Foster, who came to our rescue, appointing George Taylor as inspector, and spending a few weeks now and then through the summer to see that things were going all right.

While Mr. Taylor was gone he found many opportunities to get bees at a very low price, so secured all he could. This meant work for some one, putting together supplies and looking after the home bees; so, of course, the work fell to me. Our small son had to amuse himself, and his great delight was to get a smoker. He wore a large bee-veil part of the time, with stockings drawn up on his arms; and because he had seen "Dadge" roll his socks on the outside of his overalls he rolled his little overalls up so his stockings would show. Then he was prepared for battle. He would play all day long with this outfit, and many a time has stood right in the midst of singing bees, unafraid if he only had a smoker. His

Murton Ross Taylor, son of Mr. and Mrs. George Taylor, of Dolores, Col., age 2 years, 2 months, youngest member (enrolled by proxy) of State and National Associations. Photographed by Frank Rauchfuss.

prattle never ceased; but in the main he talked of bees and would say, "Murton better smoke bees; might 'ting me."

Then he discovered that, if he would puff the smoker at the lambs they would run and jump to get out of his way, so in this picture this is what he was doing.

Dolores, Colo.

AN HONEST ADVERTISEMENT

BY R. F. HOLTERMANN

Under "Stray Straws," Dr. Miller, page 705, Oct. 15, has something to say upon the subject of advertisements, and then he has the courage to say, "A lie is a lie, whether general or particular; in an advertisement as well as elsewhere." Then the editor, in a footnote, adds, "The time has come now when an exact and honest statement without exaggeration will bring in larger returns of money than boastful advertising that tries to make the buying public believe what it knows is not true." Both have touched upon a point of the very deepest importance to the people at large.

Many of the flaring advertisements we see, claiming certain articles as being better than any others, show upon the face that they are made by people who do not care whether they tell the truth or not. Yes, I assert it—*do not care*; because if they did they would not make them unless they *knew*. How can a person say certain goods are the best unless all others have been examined,

G. A. Barbisch, the beekeeper who can not walk, and a part of his apiary.

and there is no ultimate authority on the matter as to what is best? Then when it is the best, is it modest and becoming to say so? Many may laugh at me for speaking or writing of business modesty, and yet there are such things. The policy of some of the most successful business men has been to show forth the merit of their own goods, and not to pick holes in the other man's goods; and I can think back to purchases I have made from such people, and with my money went my profound respect and resolve to put in their way what I could. This line of "blowing" has, perhaps, wrought out its own destruction. They are read but not believed; they are no longer effectual in influencing thinking people. Besides, the superlative in description has long been reached, and we can no longer outdo the other in language.

But this is not the reason why I have opened up this subject. Let us be honest, and ask ourselves who makes any pretense of telling the truth. The honest answer is, "The person who in description does not go beyond fact." I have watched the growing habit of children of going beyond the truth, and, once begun, it grows until I have thought or said, "What will you do when you have reached the limit of language or imagination?" When a person tells me that he has seen some "great big" article, or writes of "great big fellows like you, with strength to burn" (see first item, *Stray Straws*, Oct. 15th), I say to myself that he is already digressing.

This is recorded as no jest; but many of us have heard of a lady who told the late D. L. Moody she did not know how to overcome her habit of exaggeration. Mr. Moody said, "Call them lies, madam; call them lies." This is putting the matter in its true light. If we examine our lives we must bear record to this, that, as we conscientiously value the truth, we become careful not to overstate. We may bear false witness by misrepresentation; and misrepresentation may be accomplished by telling only one side of a story. I have often had to remember the passage of scripture, "In the multitude of words there wanteth not sin." I never have perfect confidence in a person's truthfulness and reliability when he goes beyond the truth in telling a story.

Brantford, Canada.

WORKING WITH BEES FROM A WHEEL CHAIR

BY G. A. BARBISCH

The picture shown includes part of our apiary of 70 colonies, my daughter, and myself. I am sitting in a wheel chair. I hurt my spine some years ago, and can not walk; but that does not hinder me from keeping bees. I often work all day long with the bees from my wheel chair. Of course, my wife helps me all she can, and we get along well with our pets.

This season, about the middle of July, we extracted over 3000 lbs. of the finest clover honey we ever had. This locality had

a fine flow from white clover. It has never been more abundant than this year.

HOME-MADE BEE FIXTURES

BY W. L. PORTER

One frequently reads articles in bee-magazines commending the beekeeper who makes his own supplies. Mr. W. Foster recommends this in the *February Review*. I have had a long and extensive experience along this line; and while Mr. Foster has had a chance to make a good many observations I must differ with him on the subject.

In the many years I have been handling bees I have been constantly running up against the home-made hive, and it has been almost invariably in my experience that such hives are a detriment and an expensive article to any one who has to use them. So far as my experience is concerned, they are an expensive article, even if the beekeeper could get them for nothing.

I have bought a great many hives of bees. These bees are in all kinds of hives, and many of them are in home-made hives. While these hives have not caused all the gray hairs, the trouble and worry over handling home-made hives and fixtures are certainly enough to make one's hair turn gray. I do not say that a beekeeper can not make a perfect hive; but I do find in my experience that nine-tenths of the home-made hives are imperfect, and even hives made by good carpenters are off somewhere. The brood-frames are either too long or too short; the rabbets where the frames hang are too shallow or too deep (often the frame hangs so as to rest on the bottom); or the supers are too shallow or too deep. I often get hives where the end-bars of the brood-frame touch the ends of the hive; and often the top-bar is so thin that the frame sags under the weight of the honey in the frame.

It has been my experience in handling and inspecting for foul brood that the home-made hive is one of the most menacing parts of the work on account of its being almost impossible to get into the hive. The difficulty in finding lumber of the right quality and dimensions makes it almost impossible to produce an ideal hive. I have known a good many planing-mills to try to make hives to sell; but the trouble to get the proper lumber, and the mistakes they make, cause them to discontinue making them.

In moving my apiaries from Colorado to Idaho I tried to weed out all of these misfits, and broke them up for firewood. They filled a woodshed to the roof. Some of these

hives were made of the best clear lumber; but their imperfections made them worse than useless.

I think it best for those starting in the bee business to buy hives made at factories which have made the hive a study. In this way one can get the best. Then buy the same kind each year, thus having all the hives and fixtures alike. Parts of the hives are then interchangeable.

The same is true in manufacturing foundation. It is a science to handle beeswax properly. The factories exchange foundation for wax, charging from 15 to 16 cts. per pound. By exchanging, one gets the best, and avoids the muss and the expense of getting cans, press, etc., to make up the wax. I believe if a beekeeper is out of work in the winter, it is better that he should get busy raising chickens or something else that will pay, and let factories which have had experience and have the best machinery do the work of making the supplies.

Caldwell, Idaho.

BEEKEEPING IN AUSTRALIA

Getting a Queen into a Laying-worker Hive

BY MAJOR SHALLARD

Louis H. Scholl says, p. 720, Nov. 15, 1912, that he has never succeeded in getting a laying-worker colony to rear a queen successfully. I do not have many colonies in this condition, but I do not recollect having much bother in getting the bees to rear a queen. Mr. Scholl is speaking, apparently, of the attempt being made while the laying workers are still in the hive. I should think this would be impossible unless there were enough new bees in the hive to outvote them. I once found a colony in a very bad way with laying workers, with not more than a quart of bees in the hive. I shook them out, and gave a frame of larvæ, and another of hatching brood. They reared a nice queen, which proved to be a good layer.

BEES STINGING BLACK HATS.

Bees will sting black hats venomously, and will get so wild that they will soon transfer their attentions to the wearer, and drive him out of the apiary. A young fellow working for me once came to the apiary wearing a new fawn-colored felt hat. The bees took a violent dislike to it at once. In less than ten minutes the hat was the center of a cloud of angry bees, and the wearer had to decamp quickly. In this case I think it was the smell of the new felt that was disagreeable. I watched a peculiar experiment of bees stinging on one of my farms,

A bumble-bee that was obliging enough to pose for its picture.

although the operator did not intend it as an experiment. The bees here are always very spiteful during ti-tree bloom. This starts about the end of March, and has three sessions or lots of bloom, lasting in all until the middle of June. During the time of bloom the honey seems to be secreted in cycles—that is to say, the honey will come with a rush for three days, and then let up for two days, and during these spells the bees become very savage. The man I refer to was wearing an old pair of trousers all gummed up with honey and dust, and he got very few stings. Thinking, however, that they were really too dirty to wear any longer, he discarded them and put on a clean pair. A little while after, the bees chased him inside, and he was glad to get into the old ones again. He repeated the attempt to wear the clean one, three times, and then gave it up, and kept to the old ones until the end of the season.

ARE REDWOOD HIVES MORE IMMUNE TO DISEASE THAN THOSE OF PINE?

I think not. I have a lot of redwood hives in use—California redwood—and also thousands of redwood frames, and the bees become diseased just as easily in one as in the other—at any rate I can see no difference.

I am writing from a semi-tropical climate, and we get no American foul brood; but we do get black brood or what has been renam-

ed the European variety. Paralysis, or Isle-of-Wight disease, is also found.

Away down south, 400 miles, where I have my other apiaries, the American disease is found, and the other two as well, although we have none of the former in the apiaries, nor has there been any for many years. Paralysis is not nearly as bad there as here. Unfortunately we have no foul-brood law in New South Wales, so each one has to look out for himself; and if his neighbor's bees get diseased, and the owner refuses to clean up, he must put up with it. We have to be thankful that nature provides a remedy for the disease in the bee-moth and the ants. The latter eat the honey and the former the wax, and there is an end of the foul brood.

South Woodburn, N. S. W., Australia.

A BUMBLE-BEE THAT WANTED ITS PICTURE TAKEN

BY HARRIS T. KILLE

Who says that bees are not intelligent? One might think that the bumble-bee shown in the accompanying illustration possessed human intelligence by the way it behaved. I was trying to get a photo of the queen; but no sooner did I get the camera focused than Miss Bumble Bee came and posed herself right in front of it. Now, isn't that the

way most humans behave when a camera is in sight?

Another reason that makes me think that this bumble-bee possessed human intelligence is that she started to eat the minute she came near any sweets. She enjoyed the meal for about five minutes, when the Italians, thinking she had eaten enough of their hard-earned honey, began to tug at her legs and wings. She then flew away. The queen was far too modest to pose along with the bumble-bee. Instead she stole around to the shady side of the comb.

New Brunswick, N. J.

A CONCRETE BEE-CELLAR IN WHICH UNIFORM SUCCESS IS ALWAYS ASSURED

The Value of a Properly Constructed Sub-earth Ventilator

BY H. HARLEY SELWYN

In the October 1st issue, p. 686, Mr. E. S. Miller, of Valparaiso, Ind., deals with the advantages of a good concrete cellar for wintering bees. He also mentions the depreciation of hive material, especially outer casings and extra labor involved in packing hives on their summer stands.

Now, I do not know what kind of climate Mr. Miller has to deal with; but I do know this: that the construction of the cellar, mode of ventilation, capacity, percentage of loss, and cost of putting away 100 colonies so closely agree with my experience during the past four years that I can not refrain from reiterating the words of Mr. Miller.

A few years ago I undertook to construct a cement cellar (strangely enough), 16 x 20 feet and 7½ feet high, as suggested. The climate in the vicinity of Ottawa, the location of my beeyard, is extremely cold in winter; and to temper this air before entering the cellar I provided for a sub-earth ventilator for running under ground about 60 feet from the hillside (the cellar is situated on a rising ground), and entering the floor of the repository. This provides perfect ventilation, I find; and, to prove my statement further, the percentage of loss has been practically nothing. Of course there is an outlet for the foul air in the ceiling above, which passes through into the main room of the bee-house proper above. Mr. Miller recommends a chimney descending into the cellar on the lee side to take the air from the bottom of the cellar. As carbon dioxide is heavier than air, and as this gas is largely given off by the bees, it is natural to suppose that, under normal conditions in what might be a hermetically sealed cellar, it would be in large quantities

in the lower levels, and cause uneasiness to the bees; but in my experience, the heat created by 100 colonies in a compartment 16 x 20 feet has been so marked that there is always a quick-flowing current of air out of the main vent; and to fill the vacuum created, of course fresh air, moderated by its long passage under ground, is entering. For these reasons I consider this method of ventilation superior to any other, and my experience has borne me out.

The cost of labor in putting my colonies in has been about \$3.00 each fall, although it took the man I hired only part of the forenoon to carry them in and get them on the racks previously prepared. I paid him well, as he was very careful in handling each hive; and I believe in rewarding conscientious service. He has done this work for me for several seasons. I prepare the hives for moving in some time before, so that there may be no hitch in proceedings.

Each hive is given a new quilt of 6 to 8 oz. duck, cut nice and square, and leaving no holes for bees to get out after the cover comes off. Besides, a new duck quilt assures good slow upward ventilation, which I consider essential for the best of success in wintering. All hooks or crating staples are removed except one at the back of each hive, which holds the bottom-board in place and yet allows the body to rise in front, so that blocks may be inserted to admit an abundance of air to the cluster; and also to avoid the blocking of an ordinary 5/8 entrance with dead bees before the winter is half over. This should be done after the hives are in and the bees settled down.

Our winter extends over 5½ to 6 months of the year, and year after year the bees in this particular cement cellar have been in continuous confinement for that period, and yet come out strong, lusty, and clean. I do not think many beekeepers can place the reliance I do in this cellar.

Its construction as already mentioned is simple to a degree. Just clean out a 16 x 20 space 8 feet deep in a good dry hillside, having plenty of natural drainage. Put in a wooden form about 12 inches from the earth, made to hold back the cement, and fill it in day by day, taking care to leave plenty of big stone projecting from the last day's work to make good connection with the next day's mixing. When completed, one has a base for a house which is practically everlasting. Doors which sag and frames and floors swaying are unheard of and the bee-house above proves a source of satisfaction.

The ventilating system in my case was put in after the cellar walls were built. A

little tunneling under the wall was all that was necessary to pass the 6-inch tile pipe through. This tile piping serves a twofold purpose. It acts as a ventilator, and also as a drain for any water which might come by seepage in on the floor. I have had the floor cemented also, and graded to slope from all sides to the center where the elbow of the drain rises flush with the floor.

I can not too highly recommend this scheme of wintering, and I am glad to have found another who so heartily endorses it. Thanks to Mr. Miller.

Guelph, Ontario, Can., Oct. 12.

HIVE ENTRANCE MADE SMALLER BY THE BEES

JOHN VOLLMER

I discovered the hive entrance shown in the picture when about to put up my bees for winter. My wife hived a swarm in August in an observation hive. I left them in it, after covering it with a deep telescope cover, intending to put them indoors for the winter. They were a stock that could always take care of themselves and robbers too, so I didn't contract their entrance too much; but their glass walls must have been chilly, so they built a double-arched doorway to shut out three-fourths of the cold blasts. They built it of propolis, and it much resembles stucco work.

In the print, A is the hive-body; B the alighting-board; C, C are blocks to cover the longest part of the opening.

The photo is slightly too large, as the space from the landing-board up to the hive-body is about $\frac{7}{8}$ inch.

Ashland, Pa.

Hive entrance partly closed with propolis.

"BOOST" SWEET CLOVER

BY HARRIS T. KILLE

Sweet clover is on the stage to win, and it is up to the beekeepers to make it win. Within ten years, I believe sweet clover—that noxious weed which but a few years ago State legislatures took it upon themselves to eradicate—will be grown as extensively as alfalfa. But in order that this may be a fact and not an idle prophecy, beekeepers will have to do their part toward making it a fact. They will have to "boost" sweet clover. The farm papers are beginning to boost it; the State experiment stations are boosting it, and they haven't any honey to get by so doing either.

In the Sept. 20th issue of the *Country Gentleman* is an article by J. C. Mohler on "A Roadside Weed of Worth," subheaded "Sweet Clover Gives Promise of Becoming a Rival of Alfalfa on Many Soils." The facts of this article are drawn from the experience of a Mr. Fred Miller, Jr., dairyman farmer of Shawnee County, Kansas. It tells of the difficulty Mr. Miller had in obtaining seed for his first half-acre trial-plot of sweet clover. He was subjected to the severest criticism for attempting to propagate the pest. Seedsmen and farmers hooted at him. But he had fed some that he obtained by the wayside. He had found that, when placed in the feed-racks along with alfalfa, 21 out of 25 cows ate it in preference to alfalfa; so he planted in spite of hoots and criticism. Here, quoting from the *Country Gentleman*, are the results he obtained after he had planted and grown his half-acre plot of sweet clover:

The second year of my experiment I wanted to know the value of sweet clover as a milk-producer. I took ten average milch cows from good prairie and blue-grass pasture about May 10th, and put them into this sweet-clover patch. It had attained a very rank growth, and was more than two feet high. The cows were kept there two weeks, and at the end of that time had gained an average of five gallons of milk a head. About June 1st I returned the cows to the prairie pasture, and in two weeks they had lost the five gallons that had been gained.

Brought back to sweet clover, in two weeks they gained three gallons. The weather was very hot, and the clover was really too rank for the best results. But these cows maintained an excellent flow of milk throughout the season on this little half-acre tract of sweet clover. For pasture it is far better than alfalfa in at least one respect: It

contains a poisonous ingredient which is wholly harmless to stock, and which eliminates any possibility of bloating in ruminants, which is the most serious drawback to alfalfa as a pasture plant.

Horses are especially fond of sweet clover as pasture and hay, and hogs and cattle thrive on it. Chickens, big and little, like young sweet clover better than alfalfa.

As a soil-builder sweet clover is unexcelled. The two-year-old plants die. The roots, extending eight to twenty inches deep, from quarter to half an inch in diameter, decay, adding humus to the soil. Where the plant is allowed to reseed itself this becomes an annual occurrence. It breaks up the soil to admit air and water, and, being a nitrogen-gatherer, it also fertilizes the land. Ground intended for alfalfa will be greatly benefited by growing sweet clover for a couple of years before.

Sweet clover has proved of real service on worn-out upland farms for it is a soil-renovator as well as a flesh-former, a milk-maker, and a money-maker. It will thrive where not even weeds will grow. It prospers on the best soil, and will produce abundantly on barren wastes. It is the greatest thorough resister of all forage plants; its roots penetrate the hardest ground, even taking hold in crevices of rocks.

There are some facts in the above that it would be well for our farmer neighbors to know. Why not send the names and addresses of your farmer neighbors in to the *Country Gentleman*, Philadelphia, and have them send marked issues of the Sept. 20th issue to them? I'll venture to say that there will be more than one trial-plot of sweet clover in your neighborhood next year if you do. And, while you are about it, it might be well to see to it that Bulletin No. 244 of the Ohio Experiment Station falls into their hands. This will be a good "follow up," such as our present-day advertisers are using so successfully. This bulletin will give them directions for planting, inoculating, varieties, securing seed, etc.

Writing of this bulletin in *Kimball's Dairy Farmer*, Mr. W. B. Quarton, who has furnished that well-known paper with several articles on sweet clover, its value as a fertilizer, etc., says: "This bulletin is the most exhaustive thing I have even seen on sweet clover. It covers the widest field and the widest investigation. The results and conclusions attained bear out fully and completely all I have said in *Kimball's Dairy Farmer* in regard to sweet clover, and very much more. In composing these articles that I have been writing, I have been very conservative; but this bulletin goes far beyond any of the claims I have made for sweet clover; and any farmer who will read the evidences given by the 1882 farmers of Ohio as to the value of sweet clover for all purposes, can not help being convinced of the real merits and value of sweet clover to the farmer."

Here is the summary given in the bulletin referred to, showing the various soil types on which it was found growing: On the sands of the lake shore, the sandy loam,

the pure sand dunes, on the thin soil of the "opens" on the lake ridges, on the old lake-bed soils, on very heavy soils, on gravelly moraines, on black prairie soils, on disintegrating limestone outcrop, on the river bottoms, on the white loess soil, on the red clay soils, on shale banks, sandstone bluffs, sour clay, and the sandstone quarries 20 feet below the surface.

GLEANINGS has a wide circulation, but I don't believe there are many subscribers but live on or near at least one of the above-mentioned types of soil; and as Mr. Quarton, the "conservative" writer quoted above, says, "It will grow from the Gulf of Mexico to Canada," there is no reason why every beekeeper can not have a field of sweet clover growing on a neighbor's farm as well as his own by next year. Once the farmers have learned the value of sweet clover for feeding stock and renovating worn-out soil. I believe it will be grown extensively by them.

Let us beekeepers turn missionaries and introduce sweet clover to our farmer friends as a falsely condemned criminal—a guileless wayside waif—that is waiting to fill their pails with milk, their soil with fertility, their barns with plenty, and their pockets with money, if they will but transplant it from the roadside to their fields. At any rate, let us see to it that there are no Sept. 20th issues of the *Country Gentleman* to go to the scrap-pile; and, if possible, back numbers of *Kimball's Dairy Farmer* containing Mr. Quarton's articles on sweet clover ought to be circulated. And, by all means, see that Bulletin No. 244 of the Ohio Experiment Station has to be run through a second edition.

New Brunswick, N. J.

WINTER FEEDING

BY O. S. REXFORD

Our usual fall honey-flow in this locality was nearly a failure in 1912, and the bees started in for winter light in stores.

I fed late in the fall, but the unusually warm weather in December and January, I think, caused a greater consumption of honey than would have been the case if the weather had been normal. I had no extracted honey to make candy, and I knew of no other very satisfactory way to feed in winter weather. Still, if I did not do something I knew that I would lose some colonies through starvation.

When Feb. 1st GLEANINGS came I was undecided whether to try to feed in some way or to let them take their chances. I

read Mr. A. C. Miller's article, page 80, was interested, and soon had twelve colonies feeding from the Miller-Fuller candy. Yesterday was warm, and I investigated far enough to learn that the bees found it O. K. Now if I lie awake nights it will not be because I am afraid my bees will starve. Some may think that a candy which is 14 per cent glucose is not safe for a winter feed; but bees do not often need extra feed till late in winter, and I think all will admit that it is all right in February when they are sure of a flight soon. On the evidence Mr. Miller gives I believe it is all right for any time in the winter. I think that I shall try one or two colonies, taking away the honey next fall.

It was a new idea to me that a thermometer would tell when evaporation had gone just far enough. Two hundred and thirty-two degrees seems to be just right for cold weather. If for use in warmer weather after brood-rearing is started, probably it should boil until the thermometer indicates three or four degrees higher.

Any small shallow box is all right for a feeder, turned over on the brood-frames. After putting on the packing the bees are all right till the candy is consumed.

Two or three years ago I tried to feed coffee A sugar and also loaf sugar. It was not satisfactory. The sugar remained so dry that very little was consumed of either kind.

Winsted, Conn., Feb. 22, 1913.

LAYING WORKERS CAUGHT IN THE ACT

BY JUAN CHRISTENSEN

I am having some experience with laying workers which may be of interest to bee-men. I may mention that I have 16 colonies of bees about 20 miles away, and seldom see them. I have already secured 700 kilos (1540 lbs.) of surplus since October, and expect to get 300 more by the end of March. I have a lad to look after them.

About two months ago I brought some bees with a queen, and put them in a ten-frame hive across the way in this city. The bees are supposed to be Italians, but are more likely hybrids. They are two and three banded. The queen was laying, and there was a good deal of brood.

I had not been able to look into the hive for over three weeks; and when I opened it there was no brood of any sort, capped or uncapped, and no queen to be found. I got two capped queen-cells and pinned each to a different frame. A few days after, both queens had left their cells; but I could find only one, a fine-looking queen. By this time

laying workers had got started and were laying with great enthusiasm, as every empty cell had eggs, from three to eight. On the second, third, and fourth day the queen was there all right.

By this time some of the laying-worker eggs had hatched. Now, I thought that, when the queen becomes fertilized (there were a few drones in the hive), she would not have a cell to lay in. I might have starved the brood. Chilling was out of the question, as the temperature at this season is seldom under 35 degrees centigrade (95 Fahr.) day or night, but most of the cells were full of eggs. In order to experiment I took a frame, shook and brushed the bees off, and set the frame near some red ants. In three or four hours they had carried off all the eggs and a lot of the brood, and what had not been carried off yet were dead—killed by the ants. As this seemed to work fairly well, I had all the frames out, two or three at a time, until I had eight frames clear of eggs and brood.

Two or three days after, I found that every cell again contained several eggs. While looking for the queen I found a worker with her abdomen well down in a cell, and her wings flat against the combs. After sitting quite philosophically for a good while, over twenty seconds, she got out and went down head first into another cell, and then quite deliberately put her posterior part down into the cell and remained sitting with her wings spread over the cells as before. I kept my eye on her; and when she next put her head into a cell I laid a pocket-knife over her and went over the way to get a pair of pincers. With this I caught the bee by the wing and was about to put her into a pen-box; but before I got this done the wing broke and she escaped.

I continued searching for the queen, and found another bee under suspicious circumstances—that is, in the position of the previous one. I caught this one and put her into a pen-box. I continued looking for the queen, and stumbled on another worker laying. This one I lost, as she went to the other side of the frame and I could not recognize her with certainty again. Shortly after, I found the fourth worker laying, and put this one into a match-box. All four were on the same frame. It seemed to me that a large proportion of the bees looked longer than usual; but the ones I caught did not seem as long as the others, but they did seem younger. The queen was nowhere to be found, and I am certain that she must have been killed. I have gone carefully over every frame several times, and there is no queen to be seen; but I found another worker laying yesterday.

I am sure that there are scores of laying workers in that hive, perhaps hundreds, and may be all have a "try" to see what they can do at laying. I notice that all the eggs are not alike, as many are small and misshapen. Probably the older the bee when it starts self-development, the worse the egg it lays. This will also explain why a queen is not tolerated. She is a sort of Ishmael among them, and they are all against her, as she interferes with their business, wanting to monopolize egg-laying.

Santiago del Estero, Argentina, S. A., Dec. 12, 1912.

SMALLER ENTRANCES IN THE WORKING SEASON

BY FRANK M'MURRAY

Will you permit a few words in regard to large and small entrances from an old beekeeper, but one who, heretofore, has never voiced his opinions for publication touching any subject of the beekeeper's art?

It is generally conceded that entrances should be contracted during the winter and early spring; but there is a wide difference of opinion as to their correct size during the working season. Evidently, entrances may be either too small or too large during the summer months. I think a $\frac{3}{8}$ or a $\frac{1}{2}$ inch entrance the entire width of the hive an ideal one for a strong colony during the working season. Bees show their dislike for an entrance much larger, by sometimes partly closing it with propolis. A natural swarm will sometimes refuse to accept a hive with a large entrance, though containing full sheets of foundation; but I have never known a swarm to desert foundation in a hive with a small entrance. A large entrance is especially objectionable in high altitudes where the nights are sufficiently cool to chill the brood in spite of the efforts of the bees to keep it warm. My experience shows that large entrances do not check the swarming instinct, because they do not give real ventilation. If there is real ventilation, or circulation of air in the hive, there must be an opening near the top.

These observations are true of bees under normal conditions and acting normally; but bees do not always act normally. Sometimes abnormal action will be confined to a single colony; but it may spread to an entire apiary, and one can not expect bees, while acting abnormally, to follow their usual rules of action. Unusually late swarming is an abnormal manifestation of the swarming instinct. The clustering of a colony on the outside of a tree, and the spending of the working season building comb and stor-

ing honey there without any protection from storms or cold are abnormal forms of bee action. If careful discrimination is to be made between the natural and unnatural actions of bees I think it would help beekeepers to understand better the likes and dislikes of bees, thus avoiding many mistakes.

Aurora, Mo.

PLACING HIVES ON CEMENT SLABS

Sowing Sweet Clover Seed

BY C. A. BUNCH

Last fall we made 40 cement slabs for our 80 hives of bees. Two hives were placed on each slab. These slabs are two feet four inches by 3 feet 8 inches, these dimensions being just right for two 12-frame L. hives, which are reduced to 10 frames each by a division-board. Our hives face almost exactly east, and the slabs are placed the long way north and south, and are 9 feet by 10 feet from center to center, with a catalpa-speciosa shade-tree set 18 inches southwest from each cement slab.

When we made the slabs we cut 2 x 4 studding for the form, two for the end pieces 28 inches long, and the side pieces about 41½ feet long. These were laid flat on a level piece of ground, and were staked on the outside so as to make a square 2-4x3-10. This form was filled with good cement mortar. The proportion was 3 parts of sand to one of cement. This set 24 hours. Then the form was set up on edge, the cement covered with a newspaper, and another new slab was put over the one previously made. About every 24 hours a new slab was made in the manner above stated. The form was blocked up each time to the desired height until the pile of slabs was about a foot high. They were always covered in order to protect them from the sun. The pile of slabs was left thus for about 10 days until ripe. We used two forms, but several could be utilized very conveniently.

We have had one cement slab in the beeyard for 8 years, and it is just as good as new.

The 14th and 16th of December we sowed our sweet-clover seed, 5 acres on rye ground and 14 acres on wheat ground. This seed was in the hull, and the amount was 9 lbs. per acre. Later we sowed 75 lbs. of small or June clover seed and alsike on the same ground. The 5 acres are for pasture, while the 14 acres are for hay. I think in northern Indiana December is the time to sow sweet-clover seed that is in the hull. The seed is then in the ground in good shape by

spring, and there is no danger that it will perish on the ground. The ground of course was bare of snow at the time of sowing.

Lakeville, Ind.

ROBBING STOPPED BY A BUNCH OF HORSE HAIR PLACED OVER THE ENTRANCE

BY JAMES M. MUNRO

May I share with my fellow-beekeepers two real discoveries which I made in 1912? One came about in this manner: At the end of the honey harvest I was requeening my colonies. One day after dinner I opened one hive to see if the queen had been received all right. I was removing frames, had located the young queen, and had noticed a nice batch of eggs when I heard the distinct sound of robber bees. Before I could replace the frames and close up the hive they had made quite a start at robbing.

As my large smoker was in fine trim I thought that a good smoking outside would drive them home. Instead they continued to increase. Then I resorted to putting hay and grass at the entrance; but the force of robbers became so great that they would push it far enough to get in and out. I feared to add more hay lest I should smother the inmates; and, besides, I began to be peppered with stings.

As a next resort I tried a Myers bucket spray-pump; and, oh! didn't I deluge them until they hung around the hives like drowned rats? Then I let up. The reserves, however, renewed the attack. I went at it again reluctantly with the spray-pump, for it acted like a mule that kicks both ways. It squirted at the handle as well as at the nozzle, so that I got my share too. I finally gave up, owning that I was beaten.

As I walked away, expecting nothing but a ruined hive, I saw a bunch of horse-mane trimmings the boys had left near by. In my desperation I grabbed it and slapped it in place of the hay at the entrance of the hive. I wish you could have seen the halt. The bees darted back as if they thought it was some uncanny animal ready to kill them. I shouted "Eureka!" and, although soaked, I sat and watched the bees and enjoyed one of the heartiest laughs of the season. The robbing note soon died away, and they retired to their own hives.

During the rest of the season I used nothing else, when robbing started, than the wad of horse mane or tail hair, which I placed close up to the entrance of the hive. There was no danger of smothering the bees, so I could go away and start other work, quite contented that there would be no robbing at that hive. It does no harm to leave the

horse hair at the entrance till noon of the next day.

HONEY A CURE FOR BILIOUSNESS.

When ten years of age I had typhoid pneumonia. My life was despaired of; but after a long tedious illness I was able to go about with two crutches. From that time I always suffered from biliousness. Nothing seemed to help me. When I grew up to manhood I began to keep bees and to eat honey freely. It was honey instead of butter; honey instead of preserves and jams. In fact, honey three times a day. At present I do not know what it is to have a bilious attack. I attribute it to the free use of honey. Honey used in this way is not only a cheap medicine, but also a nourishing food.

Slate River, Ont., Can., Dec. 30.

HEATING EXTRACTED HONEY

BY LOUIS SCHOLL

Continued from page 797.

constructed out of concrete blocks, bricks, stone, or whatever is handiest. The illustration on page 767 will give the reader an idea of the one we are using. However, it should be borne in mind that we have changed to a deeper vat than the one shown, for the reason that we did not have entire success with this one. As mentioned, the honey in the upper parts of the cans liquefied too slowly, while the lower honey was getting too hot. This is overcome by using a deeper vat and a cover over all.

[When liquefying honey in 60-pound cans by the hot-water method, we never have any trouble in getting enough heat at the top. If the water reaches to within a couple of inches of the top of the can the honey *near the bottom* is always the last to liquefy. In our judgment, if so much heat were applied to the top of the can, there would be danger of scorching the honey in the upper part.—Ed.]

* * *

It has been said many times that it never rains in Texas; and, judging from the long dry spells and drouths to which we have been accustomed, a good many people who do not know Texas so well might have believed that the above is true. But, lo and behold! Texas has not only had rains of late, but continued rains for weeks and weeks; and the result is that washouts and floods, and damages of all kinds, were reported from all portions of the State. Thirteen and fourteen inches of rain in a few days was a common report, and creeks and rivers that had not been up for years turned into raging streams, causing much damage in many instances.

Heads of Grain from Different Fields

Solution for Destroying Grass and Weeds

I know that grass and weeds growing near the hives seem to be a matter of considerable seriousness to many of your correspondents, and the remedy seems to me to be so simple that it should require little consideration. It is known to all that merely scattering ordinary table salt in the vicinity of hives will quickly destroy all forms of vegetation, and is harmless to the bees. Any of the ordinary arsenical weed-killers, such as are generally sold by seedsmen, will also prove very effective. The beekeeper can prepare his own weed-destroyer, if he desires, by dissolving an ounce of arsenious acid and two ounces of ordinary baking soda in three gallons of water. This is, of course, a deadly poison, and should be kept beyond the reach of children. Ordinary sulphuric acid will serve the same purpose. It requires the addition of only about a pint of the concentrated commercial acid to about five gallons of water. Again, one can prepare a very cheap and effective weed-killer by dissolving 5 lbs. of copperas in 10 gallons of water. Blue stone, or copper sulphate, can be substituted for the iron sulphate in making this solution. To destroy the weeds the above solutions should be sprayed upon the grass or weeds around the hives.

BLACK MARTINS FOR DESTROYING THE MOSQUITO-HAWKS OF FLORIDA.

I note that some of your Florida correspondents report that the ordinary mosquito-hawks, or dragon-flies, are a serious source of loss, particularly to the queen-breeders. My own observation and experience for twenty years have shown me that there is nothing which destroys such enormous numbers of dragon-flies as the black martins, a large swallow which is found throughout the United States, and which should be plentiful in Florida. These birds subsist almost entirely upon dragon-flies, and it only requires concerted action on the part of those interested to provide them with the necessary boxes in which to breed. It follows, as a matter of course, that the number of such birds that could be attracted by a single beekeeper would not serve to exterminate the dragon-fly from his vicinity; but if the protection and breeding of these birds could be generally encouraged throughout the State, the number of dragon-flies would be enormously reduced in the course of one or two seasons. I might say that these swallows are not bee-eaters.

J. M. FRANCIS.

Danger of Supersedure of Queens Introduced by the Smoke Method

I should like to say a word to J. A. McKinnon in reply to his article on page 690, Oct. 1—that is, regarding the danger of supersedure of a queen in the smoke method of introduction. I have found that, if a hive is opened, in three or four days afterward the bees often ball the queen. When I find them balled, if I release them and smoke them in again in the same hive they will be found ten days later doing well. When I smoke in a queen I clean away the grass in front of the hive. The next morning I look for her dead body in front of the hive. If I do not find her I know she is all right. However, I look into the hive about ten days later; and if I find eggs and larvae I go no further. I lost just one queen this season, and none were superseded.

SHALLOW COMB TO HOLD THE DISEASED HONEY WHEN TREATING FOR FOUL BROOD.

Late last fall a friend and I bought 22 colonies of bees. It was too late to look through them to see the condition they were in. This summer there were three colonies that developed foul brood, and I want to tell how I cured it, for it was so easily done.

I prepared a new clean hive with full sheets of

foundation in nine frames. The tenth frame was a shallow extracting-frame filled with an empty comb, and was placed in the center of the hive. All the bees were brushed (not shaken) into this hive, and were allowed to remain that way for four days. At the end of the fourth day I took out the shallow extracting-frame and brushed the bees off and put a full-sized frame with a full sheet of foundation in its place. During the four days the bees had stored all the diseased honey they carried with them in the shallow frame, so I burned it as soon as removed. That settled the foul brood; and what nice new clean combs they have now, well filled with honey and healthy brood! The old hives and combs were placed in an out-of-the-way place with enough old bees to care for the brood, and to act as guards at the very small entrance. In three weeks they were shaken again with the young queen that they had raised; so, instead of three unhealthy colonies we now have four healthy ones. The old combs were melted up into wax. As a precaution against robbers the work was done late in the evening, and the combs were melted after dark. The old hives were saturated with gasoline and set on fire. The gasoline soon burned off and left the hives clean and ready for use. The frames were burned.

An A B C Scholar's Rapid Increase; Can we Have Too Much Shade for Bees?

I have been a subscriber to GLEANINGS since I started keeping bees, which was with one hive. I have since increased to 200 colonies, and this year we had over twelve tons of honey.

While I am much indebted to GLEANINGS and the A B C of Bee Culture for inspiration and knowledge, I have not seen enough said about shade for bees. While I am about to start an outyard in a young forest in a dense shade, will you kindly tell me if the shade would be good for the bees?

Beeton, Ont., Oct. 4.

CHARLES E. ARNOLD.

[The place described would be, in my opinion, too shady. Bees will not build up in spring, nor fly out as early in the morning, nor as late at night, where there is a large amount of shade. Experience demonstrated over and over again that an excessive amount of shade is detrimental. But a very moderate amount, or, to speak more exactly, shade that will protect the hives from nine to ten o'clock in the morning to two or three o'clock in the afternoon, is a benefit. If this shade consists of trees or grapevines the leaves will fall so that the colonies will be out in the open in the early spring and late fall, when they need all the sun they can get.]

The location that you describe, however, would be most excellent from the standpoint of windbreaks. For good results in outdoor wintering, forest-trees afford the best kind of windbreak.—Ed.]

Reconstruction of the Canterbury Beekeepers' Association

Readers in America and elsewhere who are interested in the doings of New Zealand beekeepers will remember that a conference of beekeepers of the Dominion was held last June, when a constitution was adopted under the name of the National Beekeepers' Association. This is framed somewhat on the lines of the American Association of the same name, and is designed to include all the beekeepers of New Zealand. After the delegates returned and had presented their report the situation was fully discussed; and the Canterbury Association, which had been carrying on the work under a federation of already established associations decided to remain as an independent body, and to push forward its

own policy. This having been decided on, a number of meetings were held, and an alteration has been made in the rules which now provide for a slightly increased membership fee, and provision has been made for objects which were impossible of attainment under the old rules. The action of the Canterbury Beekeepers' Association has been adversely criticised by one newspaper; but from accounts at hand at least some of the other associations are likely to follow suit. The Canterbury Beekeepers' Association will now push forward the export trade in honey which was commenced in a small way last season. The government will shortly issue regulations dealing with the subject, and a committee of members will see that these regulations are complied with. Meetings will be held quarterly, and it is intended to have a question-box on the table where inquiries can be put. These will be discussed, and answers supplied, which will help beginners (and advanced students) out of any difficulties they meet with.

Since the inauguration of the export trade, there has been a large increase in membership, showing that the Association's efforts are appreciated. The prospects for the coming season at present are good. Spring is earlier than usual, and weather warm. The winter has been rather dry, and there has been considerable frost. Fairly good rains fell during the latter part of the winter; and if we do not have a cold spell, such as we had last year during and after fruit-bloom, there should be a good crop. Bees are building up rapidly in many parts, and beekeepers are getting busy.

Christchurch, N. Z., Sept. 9. E. G. WARD.

[The winter in New Zealand is at the same time of the year as our summer.—ED.]

Bees Successfully Wintered in a Cold Cellar

Last winter my cellar was cold because I did not finish it until the ground was partly frozen. I put my bees (five normal colonies, one weak colony, and two very weak nuclei) in the cellar about December 5. A few days later I went to the cellar and found that the moisture from the colonies had frozen on the bottom-boards in front of the hives. I put up another door to make a dead-air space. This did not help matters much.

A short time after, we had a few days of warm weather, during which I opened the outer door in the morning and closed it in the evening. In this way the cellar was warmed so the moisture did not freeze except on cold days. I watched the bees for signs of bad wintering, but found none until early spring, when they began to roar during a few days of warm weather. The two nuclei died before spring; but the rest came out strong. One colony in an eight-frame hive covered seven frames.

Hurley, S. D., Oct. 6. MENHOLT CHRISTENSEN.

2300 Lbs. of Comb Honey and 70 Colonies of Bees all from One Runaway Swarm in Four Years

We are fast driving the saloons from Southern California, there being but four towns in our county that are still wet—the city of Los Angeles, Santa Monica, Redondo, and Venice. Our board of supervisors have just passed a strict law to stop the liquor men from sending their wares in to dry districts. One town, Glendale, has never had a saloon, and I hope it never will.

I started in the bee business four years ago with one swarm that I caught. This spring I had thirty, and took 2300 pounds of comb and extracted honey, and have seventy colonies at this time. It has been a poor year in most places in this country.

I used to take your paper when I was a boy in Pennsylvania, at the time you were interested in Helen Keller. I was a great admirer of Rambler

in those days, and also of the articles written by Ernest R. Root on his bicycle trips. I think it was in New York.

I sent to Washington for seed of the dasheen, and received word last week that they were out for this year, but would put me down on the "waiting list."

RAISIN GRAPES AND WINE GRAPES.

I saw in the Oct. 1st GLEANINGS an article asking the question why the California grape-growers do not make the grapes into raisins instead of wine. The wine grapes will not make raisins, as they are too juicy. The varieties that make raisins are the muscatel, or muscat malagas and Thompson's Seedless, or Sultana, all green grapes.

SULPHUR DUST FOR BEE PARALYSIS.

I had three colonies that showed bee paralysis last spring. I tried an experiment. I was sulphuring my grapevines with a power machine. I put the spray at the entrance of the hive, and filled them full of the sulphur dust, and in a week they showed no signs of the disease.

Burbank, Cal., Oct. 22.

W. H. REYNOLDS.

Bees in Hot Weather do not Tarry Long when Drinking Water

With the mercury 104 in the shade, and not a particle of air stirring at 1 o'clock P. M., I timed the bees at the water-tub. In making 20 tests, no bee was over 45 seconds, and none less than 35 seconds, taking its supply of water, and the next day I made the same test with the same record. I was surprised that they did not vary more in time they were on the rim of the cement tub. There were from 100 to 175 bees on the rim all the time.

Bradshaw, Neb.

C. B. PALMER.

The Bees Varnish the Inside of the Hive so that the Wood is not Porous

If some one will show me a hive that has been occupied by bees any reasonable length of time that is not thoroughly varnished on the inside, making it absolutely air-tight so far as the pores of the wood are concerned, then I will feel as if it were a mistake to paint and close the pores on the outside. You men who oppose painting hives "because it closes the pores of the wood," examine the inside of your old hives that have recently been occupied.

Rocky Ford, Colo., Oct. 21. A. S. PARSON.

[Hey, Dr. Miller, what sort of answer have you for this argument?—ED.]

Shrinkage in Weight of Comb Honey After it is Removed from the Hive

Is there any shrinkage in the weight of section honey, say in three months' time, if it is removed from the hive right after the main honey-flow?

Wadsworth, Ohio.

JACOB L. LIND.

[There is some shrinkage in the weight of comb honey, say in three months' time, after it is removed from the hive. The amount of shrinkage depends upon the atmosphere in the room where the honey is stored, also upon the thickness of the honey when it is removed from the hive. However, it is quite common to find a shrinkage of about three per cent in the weight of the honey—approximately half an ounce per pound.—ED.]

Some Colonies Affected with American Foul Brood

During my work as bee-inspector I have had quite a little experience with swarms from colonies having American foul brood. This seems to be against the theory of some of our writers, and I should like to know whether such swarms are the usual thing, or quite rare.

Salem, Iowa.

J. W. STINE, Deputy.

Our Homes

A. I. Root

Whom the Lord loveth he chasteneth, and scourgeth every son whom he receiveth.—HEB. 12:6.

TAKING CARE OF THESE BODIES OF OURS.

Just now in this present age of progress the whole wide world, especially the younger portion, is studying automobiles. Even in farming communities (at least in and around our Medina home), there are automobiles to get around in the world rather than depend on horses as we did a few years ago. And most of these farming friends have learned that automobile doctors are expensive as well as the old-fashioned kind of doctors. Automobile owners are studying up the mechanism as they never studied any thing before; and they are learning to make their own repairs instead of going to the garage. It has been a wonder to me how the boys get hold of the intricate mechanism of an automobile; and even older ones have learned by experience the importance of using an automobile—I was going to say in a *humane* way, so as to avoid the expense of running, as much as possible. Now, this is a grand undertaking. I do not know of any branch of education that is as important just now as something along this line, unless indeed it is an education that concerns these *bodies* of ours—these God-given bodies—in order to keep the human frame up to its best. The whole wide world is making great progress just now along this line.

Now, this Home paper may be objected to because both Terry and I are going to talk *exceedingly plain*; but, notwithstanding, I believe this talk will be of more help to humanity—especially *suffering* humanity—than any thing else I have talked about for a long while.

On page 657, Sept. 15, I said, "If my good friend and neighbor should get sick, down would go his teachings, or at least they would go down a little way." The above was dictated somewhat in pleasantry; and little did I dream while I was speaking that my good friend Terry was seriously ill, with a doctor and a trained nurse. While he was unable to write, the good wife gave me full particulars in regard to the matter; and already I for one began to see God's loving hand in this affliction; and instead of his teachings going *down*, I think the sad occurrence will be the means of making his teachings even *more* valuable.

With this preface I wish to give you the following, which I clip from the *Practical Farmer*; and by the way, friends, if you are not already taking the *Practical Farmer*

I think it will pay you to subscribe for it for Terry's teachings alone. No other writer, so far as I can learn, has ever undertaken to give the world, without a cent of pay, such sensible exhortations on caring for these bodies of ours, exactly as we are caring for automobiles nowadays, that they may run *thousands of miles* without a cent for repair. Here is the clipping:

ATTENDING THOROUGHLY TO NATURE'S CALLS.

This is an important matter which has never been discussed in detail in these columns. And still many thousands of people suffer more or less from lack of attention to as simple a thing as this, and do not know it is because they are violating one of nature's fixed laws. The points we wish to bring out strongly to-day are attending promptly and thoroughly to the slightest call of nature for the evacuation of the bladder or bowels. You may think this too simple a matter to pay any attention to. But let us explain how neglect works. In the rush and haste which is so common a man may fail to discharge quite all of the urine from the bladder. This urine contains poisons, usually more than it should have. Any left over in the warm bladder begins to decay. This may, in the course of time, bring on more or less irritation, and in the end perhaps inflammation, swelling of prostate gland at neck of bladder, and so on. Then in extreme cases life may be worse than death at times. Getting a little chilled, overeating, improper food, overworking, even worrying, may start up trouble on short notice. What we call a cold may bring on an inflammation in the bladder which will cause serious illness. You see nature chooses this weak point, unless there is a still weaker one, to build a bonfire to burn up surplus waste. This trouble is quite common among elderly men. The writer has known a number to whom life was almost unbearable. Some of them let the surgeon cut out part of what nature put there, and in every case the end came within a year or two of agony following the operation. The general impression is that old men can not avoid this trouble. The truth is that improper ways of living, such as are mentioned above, bring on the terrible ill. It can be relieved after one becomes badly off, so he can get along comfortably, by living as we teach. I have full faith that it can be cured; if not, it will always remain a weak point, and God help the poor man who, by some little carelessness, lets the inflammation get started again.

ATTENDING PROMPTLY TO NATURE'S CALLS.

Fifteen years ago the writer got up early and rode in an open wagon 12 miles one frosty morning. He was very cold, and should have gone straight to the water-closet when he landed at the hotel. Instead, he stopped in the office before an open fire to warm a little. And then in came a party of ladies to show us about town. Had he dreamed of the terrible trouble to follow he would have excused himself for a few minutes. But you know this was not a pleasant thing to do, with the closet door in plain sight and a sign on it. So he went with the ladies and suffered severely before he got back to the hotel. That evening he was taken dreadfully sick with what afterward proved to be inflammation of the bladder. He picked up enough in a few days to get home, and then went down flat again and suffered death almost daily. This was the beginning of the serious troubles in this line which the writer of these columns has had. Doctors proved powerless to cure. With no end of grit he set about learning to live so he could

get along comfortably. After some years he got so he felt well. He did not have to get up once in a night as a rule. The bladder become normal, and would hold full without discomfort. But, dear friends, it seems there was still that terrible danger spot at the outlet of the bladder ready almost to kill him if any thing went wrong. For years nothing did go wrong. But over four weeks ago he did two weeks' work in one by writing articles and answering many letters, trying to get ahead a little. Then down he went flat again, and suffered beyond words to express until he longed for death. He had to try to urinate every 30 minutes, and the nights were awful. But a good doctor who does not drug people, and a first-class trained nurse from the city, pulled him through. He lost his grip entirely, and had to let others manage for a time. This story of the starting of the trouble has never been told to any one before. It would not be told now, except as a warning to others. It is an extreme case; but it is risky to retain urine in the bladder when nature calls for it to be discharged. I have not given up by any means trying to make that danger spot sound; but, oh how much better never to have brought it there!

HOW TO KEEP BOWELS IN PERFECT ORDER.

It is important also that one attend to the evacuation of the bowels every time as soon as possible after nature gives a hint in this line. To neglect nature's call helps to bring on constipation and re-absorption of filth. It is well to have regular times, and never pass them by. Nature will soon drop into line. When one first gets up in the morning, and after meals are good times. Twice a day is none too much for best results; and the excrement should be quite thin so as to come out easily without straining. You see the colon, where waste is stored waiting to come out, is lined with rough folds. Excrement that is quite thin will pass out steadily and naturally. If it does not do this there will in time be some trouble, resulting the same as when one leaves a little of urine in the bladder. It is a simple matter to live so as to make waste pass out loosely and naturally. Eat all of the wheat, corn, etc., not bolted products from which the cellulose has been extracted. Eat fruit freely, fresh when possible. The vegetables are good also. Uncooked grain, like rolled wheat eaten dry, is better for this purpose than cooked. Drink freely of pure soft water. This advice comes after ten years of entire success keeping bowels loose and all right from one who twenty years ago never had a movement without first injecting water. If you have no trouble in this line be thankful. If you do have trouble you can never have perfect health until you overcome it by natural means.

HOW TO PREVENT A COMMON TROUBLE AMONG CHILDREN.

We have had a number of letters asking for a remedy for bed-wetting and wetting clothes in day time. We have been told of doctors giving medicine for kidneys in such a case. But this is all a mistake. The kidneys are all right, and so is the bladder, as a rule. The cause of the trouble is much more simple. A nurse trained in a hospital in Toronto, Can., was taking care of a sick mother. A six-year-old daughter would come in crying from play with her pantlets wet, and she wet the bed also. The mother said to the nurse: "I would give you almost any thing if you could cure my child of this trouble." The nurse said: "I will, if you and the father will back me right up for a few days." They agreed positively to do this. When the little girl came in wet in the afternoon the nurse bathed her and put her to bed without any supper, and told her she would get the same punishment every time she wet her clothes. You see, she was so busy playing that she would not stop until the bladder refused to hold more, and emptied itself. She had never been taught or trained in this line. That was simply all. She called her father, but he was as firm as the nurse. Then more attention was paid to diet, to have

it simple, plain, and wholesome. And very little water, milk, or other drink was allowed at supper time. She was encouraged to drink early in the day. In less than two weeks all wetting of clothes and bed stopped. The child showed the result of training by an expert who knew. Much drinking near the close of the day, and an excess of poisons in urine from improper food, hasty eating, etc., make the trouble. The poisons mentioned irritate the bladder of the little one, and she is sleeping too soundly to awaken, and the result is a wet bed. We have waited to answer the questions in this line until we had positive proof from some one we could depend on that the trouble could be stopped in a short time. But let us beg of you not to give the little ones any of the drug "cures" that are advertised. Simply remove the causes of the trouble.

The above almost made me smile to think how plainly Terry has outlined a physical trouble that has followed *me* through life. When I was but a baby, after a severe sickness that nearly took me away this trouble followed me. Yes, I groaned and wept over it until I was a dozen years old. It seemed almost *imperative* that I should be in the open air, and this, perhaps, explains somewhat my love for gardening, chickens, bees, etc. In traveling I have learned by sad experience the importance of hunting up water-closets; and when I go to a convention my first move is to go to the janitor and find out about water-closets. If they are locked up I find where the key is kept. When I am invited to attend some meeting where there are to be two or more addresses without a recess I am often obliged to stay away on that account. Here is another point: You know I have been vehement about the matter of ventilation (as has also Mrs. Root) in a crowded church or hall. I have been over to friend Terry's since his sickness, and was pleased to see him outdoors with an umbrella, in a rain. I asked him a lot of questions.

"Mr. Terry, when did you have the first intimation that this trouble was coming on?"

"It was while I was in church."

"Was that church poorly ventilated?"

"It was."

There you have it, friends. This trouble of mine is always worse when I am obliged to remain in a room full of people without any precaution being taken to admit *fresh* air. You may suggest I might get up and go out. Yes, so I could; or, rather, I could a few years ago. Since my deafness has come on, however, I am obliged to sit on a front seat close to the speaker; and I think many of you can understand how awkward it would appear for me to get up and go out, especially if I had just given a hearty "amen" to some good point the pastor made in his sermon. I am glad to note that of late the sermons here and down in Florida are getting to be short and to the point;

and I do not believe it is well or profitable to have two or more important addresses without some sort of recess between them. Terry alludes to the care of our diet; and this opens the way for me to repeat that I have never in my life found any thing so beneficial for such troubles as *grapefruit*. Here in the North it would be rather expensive; but in our Florida home we have always been able to keep a supply at so small an expense as to be scarcely worth mentioning. May God be praised for such a delicious health-giving medicine as grapefruit. Sitting down at a desk reading and answering letters for hours at a time greatly aggravates the trouble, and that is what brought back once more friend Terry's trouble of years ago. I think he is now pretty well past the difficulty, and I hope his prospects are *still* good that he may live to be a hundred years old. But the matter rests considerably on the shoulders of his good friends scattered far and wide; and if you want to see him keep on with his teachings for years to come, let me beg of you to be careful about writing him long letters; and whatever you do, inclose an addressed postal card as I desired in my case. I talked with him about it. He said *my* request was all right; but as much that he has to say to his friends would hardly be appropriate on a postal, he urges an *addressed* stamped envelope.

In conclusion I begin to think that Terry's painful experience during the past few days has really been in one sense providential. It enabled him to form a close acquaintance with one of the best doctors and one of the best trained nurses. I know something about the good woman, because she was employed, years ago, as I understand it, by a member of our family.

One other thing I said to Mr. Terry:

"Friend Terry, are you having outdoor exercise every day of your life, enough to start perspiration?"

"Mr. Root, I have not had the time. In regard to outdoor air, we have it already. It is right here in this room, as I have explained repeatedly."

"Yes, my friend, this air *is* all right. It is delightful. I had not noticed it particularly till just now; but, notwithstanding, I feel quite sure it is not equal to being outdoors and hard at work at something till the sweat starts."

I confess it was a little funny, the idea for just a moment, of *Terry* being a patient and your humble servant the doctor; but I think my good friend agrees with me, even if he did not promise to take "my prescription."

Last, but by no means least, besides the

exercise in the open air, I said something like this:

"My good friend, do you ever take a nap during the middle of the day?"

"I do not need to, Mr. Root. I sleep well and soundly all night; and I do not think that getting into the habit of sleeping in the day time would be any advantage."

I do not recall what I said in reply to this matter, but as I deem it of great importance to elderly people I want to go over again what I have been urging repeatedly.

It was about 35 years ago that Dr. Salisbury warned me against sitting down to dinner or any other meal when *tired out*. He said my digestive apparatus could not do its work, and do it well, no matter how well the food was prepared, unless I was well rested up before eating. He declared it would add *ten years* to my life if I would leave my work (then mostly at the desk), go home, and get some sleep. Ten or fifteen minutes' sleep, he said, was better than none at all. Well, it has added certainly ten years to my life, and may be twenty. You remember how vehemently I have urged it, especially for elderly people.

Some of our good hard-working mothers have intimated that it was a huge joke to ask the average *mother* of a family to go and lie down during the very busiest part of the day, just before dinnertime. I think I realize something of what a task it would be; but could it not be accomplished easier than to have the tired mother go off to a sanitarium to be doctored, or possibly off into her eternal resting-place before her time? Well, during the past year or two I have found several times that, after this brief nap before dinner, I was not even yet in first-class trim. When I have the use of all my faculties and enthusiasm besides (as I have just now), I can do a lot of work in a little while, and do it well; but, as I have just said, for the past year or two a good many times a brief nap and a dinner afterward did not quite get me in "fighting trim." My "storage battery," if you will excuse the illustration, was not even yet well charged; and half an hour in the garden, so as to start perspiration, did not bring the vim for my work that I usually have. What was the trouble? I told Mrs. Root that I was forced to the conclusion that I had not had *sleep enough*. I often sit up to read as late as ten o'clock, and am often up by half-past four in the morning.

Now, what I am going to say is for elderly people. The younger ones, full of life and vim, may call it nonsense; but after I went back to my comfortable resting-place and slept an hour, sometimes even more than that, I was ready to swing my hat and

say, "Come on, boys; bring on the work you want done, no matter what kind, and no matter how unpleasant."

The above is simply treating these complicated bodies of ours—yes, bodies and brains—just as you would treat an automobile. Sometimes it bothers even the experts to tell just *what* the matter is. They try one thing and then another, and so on. But if they *persevere* the inanimate machine finally goes off at its full power. Now, be careful not to mistake downright laziness for a break or a weak spot in the machinery. If laziness, hoeing in the garden will generally cure it. Ask God to guide you; and when he answers your prayer, and gives you the needed strength and energy, "get busy" with something that will *help* weak and suffering humanity.

ARE OUR BANKERS AS A RULE PROFESSING CHRISTIANS?

Mr. Root:—I note what you said about bankers attending church. *The Adult Bible-class Monthly*, published by the David C. Cook Pub. Co., says that bankers are the best Sunday-school superintendents, and that very many superintendents or a majority of them, I think, are bankers. That looks as if it were quite fashionable for bankers to undertake church work.

I am glad to say that I am a "chapter-a-day" Bible-reader. I have read from the beginning to the book of Judges. A class of us began last December to read the Bible through.

Andover, Ohio, Aug. 4. CLINTON D. HATTON.

Thank you, my good friend, for correcting me. I am rejoiced to know that some of our bankers are professing Christians. God knows they should be professing Christians, not only on Sunday, but every day in the week; and who can tell how much good they might do if they applied the Christ-like spirit to every business transaction?

SHOES FOR HOT CLIMATES; SPANISH ALPARGATAS, ETC.

I received June 15th *GLEANINGS*, and I saw on page 18 something about Spanish alpargatas. Here they are generally used by the laborers, and lower classes also, 12 months in the year, as well as children of both sexes, for going to school; but they are not rope-soled, but leather-soled. They have been imported from Caracas for 15 years, and gradually became generally used. As in Venezuela and other South American republics, they are generally used by the lower classes. The price is from 20 up to 48 cts., according to size.

Rope-soled slippers with cloth uppers are used indoors by the well-to-do, and cost from 16 to 20 cts.; but they do not stand the wear and tear of the leather-soled ones. I can not tell you where they are imported from. The real alpargatas, leather-soled, are both imported from Caracas and manufactured locally in ever increasing numbers. They are usually worn without socks or stockings, although some do it so. There is also the rope-soled slipper for the Chinese, round at the end, to be used

indoors. Their price is 15 cts. They are straw right around at 15 cts. I am sending you a sample of each for your inspection and use. The rope-soled is 18 cts.; the alpargatas, 40 cts. Alpargatas are imported from Caracas; rope-soled from Germany, and the straw ones from France, as they informed me at the store. C. M. CARMONA.

San Rafael, Trinidad, B. W. I., July 15.

The good friend who writes the above has kindly sent us three pairs of these cheap shoes as samples. The Chinese slippers made all of cloth, for 15 cts., would answer very nicely indoors. Moccasins with rope soles would, no doubt, be all right for wearing outdoors in dry weather. I think they would be especially handy for a tramp through the woods, keep the feet cool, and yet give sufficient protection. The alpargatas at 40 cts. have a good substantial leather sole with cloth uppers. I am glad to say that I find my strength holds out very much better, in hot weather especially, when I wear a shoe made of cloth or of cloth uppers. Abundant ventilation for the feet, and a sort of ventilation that can not be secured with leather uppers, is, I think, exceedingly important. And, by the way, it is important, as I said before, that the whole body be well ventilated, especially in hot weather, or in the hot sun. If you do not keep this in mind, and look out for it, you will suffer more or less unless you are built after a different fashion from what I am.

Many thanks to the good friend who has helped to keep me posted in this matter.

SHOES FROM ALL OVER THE WORLD, AND SOMETHING MORE ABOUT THE CARE OF THE FEET.

Just a word more about the shoes. After having samples sent me from different nations I have found that the women's cloth shoes we find in our shoestores—at least here in the North—are the best for my special wants. I have worn one pair almost constantly since I came back from Florida in the spring. I have not suffered a minute from hot and burning feet as I did when I wore leather shoes, and my corns have not been touched by knife or corn-plaster. They are all going away of their own accord. Of course, these cloth shoes have leather soles. They cost me \$1.25 up to \$1.40 here at our shoestores. I prefer them to the various kinds of shoes used in hot climates because I can work in the garden with them and not get pebbles and sand in my shoes. Most of the shoes mentioned above permit dirt and gravel to get in between the shoes and stockings, and I am too nervous to get along with even the smallest pebble in my shoe. These cloth shoes tie up close around the ankle; and

unless you get in very deep sand there is no need of pulling them off to clean out your shoes.

One more very important thing: My feet as well as my whole body are thoroughly washed every morning of my life; and I tell you it is worth a whole lot to be entirely emancipated from nerve-racking corns and sore feet. Mrs. Root objects to these women's cloth shoes because it looks effeminate; but in view of the relief I have had I can afford to be "effeminate," and I can afford \$1.40 for a neat pair of shoes every three months if need be.

I forgot to mention that the Chinese cloth shoe at 15 cents is a splendid thing to wear around evenings indoors. There is a cloth cushion under the heel, and this fifteen-cent shoe might do a lot of service if worn only indoors.

FAKE WEATHER PROPHETS, ETC.

A few days ago I was asked if science or any thing else could tell us whether the coming winter is going to be severe or mild. I said at once that nobody on the face of the earth could tell any thing about what the coming *winter* will be. It is true that every little while we see something in the papers to the effect that the Weather Bureau says we are going to have a "hard winter," etc. The Weather Bureau has *never* said any thing of the kind, and has for years been contradicting such reports. Just lately the Weather Bureau has been at times able to come pretty close to what the weather *might* be in certain localities for a week ahead—never more than that. Let us consider the matter a little. With the automobiles we have now, and swift methods of travel, anybody with his eyes open can see that a large part of the weather is a *local* matter. A severe thunderstorm comes up, and the automobiles slip on the clay roads so they can not travel. Five miles away it is dry dust. A big wind does a lot of damage in one town, while twenty miles away (and even in the same town) there is little or no disturbance. Now think of the difficulty of putting in print, as the weather-quacks do, what the weather will be for months or even a whole year ahead! The way some unthinking people are misled is like this: A weather prophet predicts a cyclone at such a time, but he does not say where. He finds out that somewhere in the United States there *was* a cyclone at just about that time. He gets a photograph of it (which is not at all difficult nowadays), then places it before the readers of his publication and says, "Read what I said *would* happen. Now, here is what *did*

happen." If this forecaster had declared there would be a terrible windstorm on Lake Erie at such a time, or say in Northern Ohio and a part of Michigan, it would be a little more definite.

I have made two clippings from the *Scientific American* for Nov. 1, as follows:

A weather prophet's confidence in himself is always in inverse proportion to his knowledge of the laws of the atmosphere. The intelligent meteorologist is the most modest of forecasters, for he realizes more keenly than any one else the endless complexity of the phenomena with which he has to deal, and the extent to which his conclusions are likely to be vitiated by unknown factors in the problem.

By far the most numerous group of prognosticators ascribe supreme influence in meteorological matters to the moon. Another group stakes its reputation on sun spots. Some years ago the hypothetical planet Vulcan was a favorite with these seers. Others exploit that perennial refuge of ignorance, electricity.

A good deal was said years ago about animals having an instinct that warns them of a coming winter as to whether it will be exceedingly severe or otherwise. I hardly need take space to go over here about the squirrels laying up more nuts when a cold winter is ahead, the chickens putting on more feathers, etc. No doubt these things do happen. The squirrels gather more nuts because there are more to be gathered. The chickens put on a heavier coat of feathers because their owner has furnished them more and better material to make bones and feathers than they ever had before, and so with all these other things. Our United States Weather Bureau has made careful observations, and kept accurate tables for years; and just as soon as any real truth comes to light about the animals, sun spots, or the influence of the moon or planets, our great eager public will quickly be apprised of the fact.

FARMING ON PAPER; THE GOOD TIME COMING.

The auto on the farm arose before the dawn at four. It milked the cows and washed the clothes and finished every chore. Then forth it went into the field just at the break of day. It reaped and thrashed the golden yield and hauled it all away. It plowed the field that afternoon, and when the job was through it hummed a pleasant little tune and churned the butter too, and pumped the water for the stock, and ground a crib of corn, and hauled the baby round the block to still its cries forlorn. Thus ran the busy hours away by many a labor blest, and yet, when fell the twilight gray, that auto had no rest. For while the farmer, peaceful-eyed, read by the tungsten's glow, the patient auto stood outside and ran the dynamo.—*Orchard and Farm*, San Francisco.

The above is tiptop, although it does not tell who bossed that farm auto from daylight till bedtime. As California is putting her good women in the foreground, we presume it is the farmer's wife or daughter who keeps an eye on the efficiency of the dynamo while the farmer reads his paper.

High-pressure Gardening

DASHEENS IN OHIO; HARVESTING THE CROP.

On page 782 of our last issue I mentioned how the dasheens recovered from the frost. Well, they kept on growing—that is, when it was not too cold—until Oct. 20, when we had a cold rain that turned to snow with piercing southwest winds; but the dasheens did not seem to mind it at all. They seemed to be even hardier than tomatoes, lima beans, etc. Finally, on the night of the 21st the weather cleared off and we had not only a frost but a *freeze*.^{*} But, thanks to the thermometer and barometer, I knew what was coming, and on the *afternoon* of the 21st I harvested my dasheens. It was a rather cold and muddy job. If grown in sandy soil there would not be much trouble in shaking off the dirt; but in a clay soil, especially during a wet and muddy time, it is quite a task. I did not find out the best way until I had experimented a little. As the central corm has a cluster of tubers all around it, the great mass of hairlike roots holds the soil quite tenaciously. You will need a good stout spade—a curved ditching-spade, for instance, with a long blade. Get this under the whole trunk, then raise it up (if you are strong enough), and let it drop on the hard ground, if it is not too muddy to find such a place. Now take your sharp spade and trim off the roots as close as you can to the tubers without cutting them. Tip the clump over and trim off the bottom in the same way. Now take each tuber by the stalk and snap it off from the central corm. Strike it lightly against your spade, and then most of the dirt will rattle off. Throw them into empty potato-crates, and carry them in, especially if frost threatens.

Now, as it was somewhat of a question how much of these green tops are fit to cook, I trimmed off one lot, picking off the larger leaves, leaving the most of the center leaf stalk. Then I cut off the top clear down to the tuber. I told Mrs. Root that, for an experiment, I had included some pretty large leaf-stalks that might prove to be too old; but, to my happy surprise, the "stew" was delicious—every bit of it. The directions in the bulletin from the Department of Agriculture are to wash the shoots—in fact, the whole plant—in water to which a teaspoonful of sal-soda has been added to every quart. Pour this off, and

boil the shoots for ten or fifteen minutes in clear water. Pour off this water also, then stew about five minutes, add butter and milk, and serve as you would oysters, but Ernest and Huber think they resemble more nearly real nice *mushrooms*. The tubers surrounding the central corm can be cooked in the same way, or they may be dried and baked, and the same with the big central corm. But so far we have not found them—that is, the greater part of them—equal to the tubers, say about the size of a hen's egg, that grow around the big ones. I have, I think, demonstrated that the tender shoots above ground are worth the care and cultivation, to say nothing about the tubers; and I am hoping that, when the tubers are thoroughly dry, they will be as rich and luscious as those that grow further south. This remains to be proven, of course. For experiment I left one of the largest plants out in the freeze. The frost killed it down to the ground; but I hardly think it did any damage to the tubers where they were pretty well under the surface.

Later.—To-day is October 25, and we have been having a dasheen stew made of the shoots or tops, as described above, at almost every meal, and I think I shall like them the year round as well as Irish potatoes. We have passed them around the neighborhood, and they all seemed to be pleased with them. The little plants mentioned on page 697 were, at the time of the frost, out of the ground perhaps two inches. They were protected simply with burlap grain-sacks which were taken off as soon as the ground was well thawed out, and seem to be unharmed. They are, in fact, to-day making a new growth since the frost. From this I gather that it is a very simple matter to protect them with grain-sacks or something similar while the plants are quite small.

THE NEW APPLE, THE OLMSTED SWEET.

Friend Root:—I suppose you will not object to my addressing you as "friend," for I am a beekeeper, and you can't deny being a friend to beekeepers. I am also taking the liberty of sending you a parcel-post sample of a variety of apple that I think may be new to you, knowing that you are usually interested in new things. They were originated by my grandfather several years ago, and I do not know whether they have ever been handled by any nursery company or not. They are known hereabouts as "Olmsted Sweets." I am curious to know whether they are new to you, and your opinion as to their possibilities as a marketable apple. They do not make good sauce, but are used considerably for preserves, and are a favorite baking apple with a good many people here. The trees are heavy and regular bearers, and there are a great many of them scatter-

^{*} Most of our readers are aware that a severe blizzard on the 21st did much damage all over the North; and I notice by the papers that they got a touch of it clear down as far as Northern Florida. This blizzard, accompanied with unusual frost and freezing, as early as Oct. 21, is unusual. Some of the papers stated that no such severe weather had been known on that day for 25 years past.

ed about the orchards here. The apples are ready to pick from Sept. 20 to the first week in October.

Monona, Iowa, Oct. 14. D. N. OLMSTED.

The apples came to 'hand in tolerable order, except that one end of the paper box was broken, and one apple mashed. I tasted this one, but it was not ripe enough to judge of the quality. The apples are very large, beautifully streaked, and very handsome. Except the mashed one they are as hard as rocks, so I infer they are late winter apples. I sent a couple of them to the Horticulturist of our experiment station. Below is his reply:

Dear Mr. Root:—The apples which were sent you by Mr. D. N. Olmsted, and forwarded to me, came this morning. They are quite large, greenish-yellow, nearly covered with red, resembling Wolf River in outward appearance. The flesh is tender, sweet, and of excellent flavor. For eating raw, most people would regard this as very choice. The core is not large, and for baking it must be excellent. For making apple-butter I should think it would be unsurpassed.

For the family orchard it seems to me that we have nothing better of the same season of ripening. I do not recognize the variety as having been described in the fruit-books. I should think that Mr. Root could eat all he wanted of this apple, even if it was just before going to bed.

W. J. GREEN, Horticulturist.

Wooster, Ohio, Oct. 25.

It occurs to me that this apple would be a splendid one for the restaurant that advertises baked apples and cream. I have many times paid 15 cents for a big baked apple and a little pitcher of cream, and I felt that I had got my money's worth too. Very likely friend Olmsted will be able to furnish grafts in the spring.

"THOU SHALT LOVE THY NEIGHBOR AS THYSELF."

Brother Root, you have done your neighbor Rood an injustice by taking a vessel for milk that would hold more than a pint. You tell in a late issue of GLEANINGS of buying milk from him, "and a very generous pint it is." Now, by all means when you go back to Florida get a pint milk-bottle; and when you buy a pint of milk your neighbor will not be obliged to put in more than you are buying. My wife sells milk, and many times I notice she will give a pint and a half for a pint because the people bring all sorts of vessels to get the milk, which I think is an injustice. If we expect more from a party than we are paying for, we are not giving him a square deal.

I keep a few bees, and from 100 to 300 chickens—a cow, a horse, and I have several acres of land with several hundred fruit-trees planted thereon. I have a general store in a small way, and am operating a coal-mine employing 15 to 40 men. I come in contact with many kinds of men. Nearly all are expecting the best of the bargain, which, you will agree, is very wrong.

THOMAS HARRIS.

New Florence, Pa., July 26.

My good brother, I stand corrected; and hereafter when I go over to neighbor Rood's for milk I will carry something that holds just a pint. It is true, however, that neighbors who are on very friendly terms often have a fashion of giving liberal measure.

Just of late, to correct the very thing you are talking about, our State of Ohio has passed a law requiring grocers to sell potatoes, fruit, etc., by the pound instead of by the quart or peck. This cuts out the scant measure and the other extreme of heaping up the quart box or half-peck. With eggs we pay for a dozen and get exactly a dozen, and I am sure it will be better all around to be more careful and exact in these things. A good friend who is a market gardener in Florida sells stuff without a box, measure, or scales. He said he knew he was giving me more than half a peck of potatoes, but he was too busy to provide himself with scales and measures. When I told him I feared he was not getting pay for his time and trouble he admitted that it did not pay. He said he had the stuff, and must get rid of it. I am afraid it is true as you state it, that nearly all the world are "expecting the best end of the bargain." Now, may God help us (you and me) to be an exception to this prevailing fashion.

HOECAKE—HOW TO MAKE IT, ETC.

I wish to thank the good friends for the number of recipes for making hoecake, johnnycake, corn bread, corn pone, etc. While many of them are quite elaborate, using eggs, milk, etc., my impression is that the old-fashioned genuine hoecake is quite simple, and I should not wonder if it were just as good, and perhaps more wholesome. From among them I select the following, which I think might be properly called genuine hoecake. You see there is not much fuss nor bother about it.

I noticed in GLEANINGS that you wished a recipe for hoecake. The following is one. Put one quart of white corn meal into a bowl. Add one teaspoonful of salt. Add to it sufficient boiling water to moisten, stirring all the time to make a stiff batter. Moisten the hands in cold water. Take a tablespoonful of the batter in your hand and press it into a thin round cake.

If you have an open fire, have before it an oak plank well heated. Place the cakes against the board in front of the fire. Bake on one side, and turn over and bake on the other until thoroughly done—about 45 minutes. These can also be baked on a griddle on top of the fire. When done, pull apart, butter, and send to the table hot.

CHAUNCEY D. STAHL.

Little Falls, N. Y., July 11.

APPLES AND MUSHROOMS.

Three judges of the court of appeals, who were to sit in Medina, Ohio, yesterday, found no cases awaiting them. So they hunted apples and mushrooms instead. They returned to Cleveland late in the afternoon, tired out with the tramp they had taken.

The above (from the Cleveland Plain Dealer) is pretty fair for Medina Co., but not quite equal to the way they dispense with courts and lawsuits in Kansas.

Poultry Department

THE POULTRY BUSINESS—A COMMON-SENSE
BIRDSEYE VIEW FROM THE DEPARTMENT
OF AGRICULTURE.

From a farmers' bulletin entitled "*The Agricultural Outlook*," under the head of "Meat Shortage," I clip the following:

Most of the poultry products of this country are produced on farms under conditions that render the cost of production nominal. Most of the food consists of waste grains, insects, etc., which cost nothing. Most of the labor required is done at times that would not otherwise be profitably employed, or by members of the household who would otherwise be earning nothing. The farm price of poultry products is largely fixed by this nominal cost of production. Under such conditions, it is only the exceptional individual who can make poultry profitable as a major enterprise. There is, therefore, no prospect of increase in products of this class in greater ratio than the increase in population.

Now, a great lot of you, or perhaps I should say a great lot of us, need to take note that it is "only the exceptional individual who can make poultry pay, as a major enterprise." If you can get great big prices for your chickens, that may make a difference; but by the "egg contest" now going on, people are beginning to decide that "handsome is that handsome does." If you can breed a strain of great egg-layers, and demonstrate that you have such birds, you can get good prices for them. But it must be the outcome of genuine, hard work. People are tired of being humbugged.

Below is something I have clipped from a periodical called *Profitable Poultry*. For a long time I have been worried in regard to this matter. Read it and see what you think about it.

There is one thing which the writer believes almost impossible to accomplish, and that is, to raise chickens that will win, both in a show room and in an egg-laying contest. Beauty or egg production must be sacrificed to a certain extent, in order to increase the standard of one or the other.

Right here is something more along this line, from the *Industrious Hen*. I clip it from an article in regard to the Sicilian Buttercups:

It is urged that they do not breed true to feather; and fanciers who think more of a feather than they do of an egg will think this is a serious objection. Right at this point is a chance for discussion. Shall we sacrifice laying qualities to fancy? In their native island, Buttercups are kept solely for eggs and meat, with no thought as to feather markings; so that, when rightly interpreted, the criticism that they do not breed true to color becomes really a tribute to their worth.

The above is true. A great many are disappointed to find very few of the Sicilian Buttercups having a dot on a yellow cream-colored background; and I feared the tendency was going to be to pick out these

handsome hens for breeders, with little or no attention to their egg-record. I say, give us eggs, first and foremost; and if the hens happen to be handsome, golden-spangled, etc., all right; but do not, I beg of you, make fancy feathers first and foremost.

POULTRY AND BEES BOTH, ETC.

A POWDER TO KILL LICE ON POULTRY.

Take 5 lbs. plaster Paris; $\frac{1}{2}$ pint crude carbolic acid; $1\frac{1}{2}$ pint of gasoline. Mix all together thoroughly, screen through fine wire cloth like window-screen; dry in the sun two hours, and store in a tight vessel till used. Be careful of fire.

A MACHINE TO DUST HENS WITHOUT CATCHING THEM; FOR LEGHORN SIZE.

Make a drum of reasonably stiff sheet iron 12 inches in diameter and 4 ft. long, and fit a round head or end in both ends, and cut a hole 6 x 8 inches in each, and fit a slide door of sheet iron over both holes in the ends. Bore a 5-16-inch hole in one of the wooden ends, and put a bolt from the inside to stick out for a crank; then bore a hole through a stick for a handle, and screw the burr on.

For the stand for the drum to revolve upon, make a box without top or bottom with two end boards in each end, 3 in. apart, 2 $\frac{1}{2}$ ft. long, 21 in. wide, and 10 or 11 in. high; then cut out of the center from the top of the four end boards a half-circle 12 $\frac{1}{2}$ in. long, and 6 in. deep; then adjust four rollers between each of the two end boards equally spaced. Where the half-circle is cut out, have the rollers stick above the boards so the drum will rest on the rollers. To use, adjust the opening in the drum in the end without the crank to an opening in the hen-house that the hens have been using to go through, and put a screen over the hole in the end where the crank is, so the hens can see through. Put in the insect powder and drive ten hens in and close the slide doors in both ends of the drum, and revolve the drum twice each way; then open the slide doors quick.

I will tell you a little about my bees. They gave me 2000 lbs. of honey, and I have 53 colonies in winter quarters. I winter them in the cellar, but I make two sizes of hives to take Langstroth frames. The small size holds ten frames, and the large one is 2 ft. long and holds 15 or 16 frames. In early spring and late in the fall I put the large size on the small one or around it, and turn the bottom-board over so there will be an air-space on all sides and on top—that is, I use the large size for an outer case, and in warm weather they are single-wall hives.

Moscow, Pa., Jan. 14. GEORGE E. ROZELLE.

The suggestion given above in regard to dusting the hens without catching them, and doing ten at one clip, is quite ingenious, and I think it might be a great saving of labor where vermin get to be very bad; also making a double-walled hive for winter of the same hive that is used as single-walled in the summer time might prove to be quite a convenience. The long hive holding 15 to 16 Langstroth frames is what was called years ago the Long Idea hive; and if I am correct our good friend O. O. Poppleton down in Florida is still making use of these same long hives.

Temperance

MORE WHISKY CONSUMED THAN EVER BEFORE
—IS IT TRUE?

We clip the following from the *Union Signal*:

BIG SURPLUS OF WHISKY MAY CAUSE DISTILLERIES TO CLOSE.

The question of whether it may not be wise for the distilleries all over the country to close down during 1914 because of overproduction and large stock on hand in their warehouses is being raised by several distilling firms of Kentucky, according to the *Chicago Tribune*. These men assert that the overproduction was so great during the fiscal years 1911, 1912, and 1913, that a "panic" in the whisky business will result in 1914 if something is not done to prevent it. One Kentucky distiller recently told the correspondent of the *Tribune*, "There was such a nationwide overproduction of distilled spirits during the fiscal years of 1911, 1912, and 1913, with 1914 starting off with the biggest deluge of all, that the trade of the country is justly alarmed. Propositions are being launched to curtail production, even to the extent of closing down distillery operations. Each of these years in turn has broken all previous production records in the history of the industry. As a result, there remains in the bonded warehouses of the United States, after a complete deduction of all withdrawals, a gigantic net total of 274,648,260 gallons."

All of which is in perfect accord with the explanation that has been given by the temperance people of the increasing consumption by the people of the United States of alcoholic liquors.

I am assured from several sources that the statistics given us, claiming the consumption of whisky is constantly on the increase, emanated from a statistician in the employ of the government, who neglected to tell us that his figures represented the amount of liquors in *bonded warehouses*, and not the amount that had been already *consumed* by our American people.

HALF A MILLION DEPRIVED OF THE MEANS OF A LIVELIHOOD (?)

Percy Andreas says that, if prohibition should prevail, five hundred thousand people would be deprived of a means of livelihood. Well, if prohibition shall prevail, about five hundred million people will have a far better way of living. Let that principle rule that gives the best to the most.

In Elijah's time, the messenger had to look seven times before he saw a cloud in the sky, and then it was "no larger than a man's hand," yet Ahab, the politician, had "to get in out of the rain." To-day, here and there on the political horizon, clouds are appearing. May they mean the abundant rain and "reign" of pure water.

In Nehemiah we read: "And I looked, and rose up, and said unto the nobles, and to the rulers, and to the rest of the people: 'Be not ye afraid of them; remember the Lord, who is great and terrible, and fight for your brethren, your sons and your daughters, your wives and your houses.'" Get into the fight.

MINNIE J. ELLET.

It has been said that a prophet is not without honor save in his own country. Well, our good friend who writes the above in the *Akron Beacon* is not exactly a prophet, but she bids fair to become a

prophetess; and I think, too, if she keeps on with such assertions as the above she will eventually receive honor in her own neighborhood and community. Amen to Minnie J. Ellet.

THE GREAT WAVE OF CRIME IN BIRMINGHAM, ALABAMA.

We clip the following from the *Birmingham Ledger*. It is from a traveling drummer who seems to be familiar with the circumstances.

Just think of 315 homicides in Jefferson County last year! Is the reason given by your coroner the prime reason for this slaughter? I think not.

I have visited Birmingham for three years without the open saloon, and have seen her for a year with the open saloon spreading its frightful influence over that city until her people are becoming alarmed at the wave of crime and evil sweeping their fair city.

What else can the people of Jefferson County expect as a result of these places of vice and shame? Do they not go hand in hand with crime and murder?

What class of your citizens carry pistols and lurk in the dark to strike down their unsuspecting victims? Certainly it is not your sober, industrious, peaceable, law-abiding citizens.

No, the pistol-toter frequents the saloon and houses of prostitution, and, while inflamed with whisky, is seeking trouble, and is prepared for it, and is a natural product of the saloon. To my mind the open saloon which the voters of Jefferson County have allowed to exist in their midst is responsible for this wave of crime sweeping over your city, and the responsibility is upon the shoulders of the voters of your county.

Should I want to move to Alabama to rear my children I certainly would not want to bring them to a city (much as I admire that city) where life is so cheap and virtue is regarded too loosely. I hope to see a moral wave begin to spread over your fair city which will sweep these festering places of evil and crime out of their midst, and then with the cause removed you can see some of the effects removed, and your city and county officials will not have to explain to the people the reasons for such conditions as now exist.

A DRUMMER.

THE TEMPERANCE WORK IN NEW ORLEANS.

When our great city dailies begin to lend their influence to the cause of temperance, something is going to happen. The clipping below from the *New Orleans Item*, taken from Congressman Hobson's speeches, is only a small part of half a dozen columns of similar matter:

Meat with strychnine placed along the streets will kill the dogs. No terrible examples will have any effect. The fact of the poisoned meat being placed on the street is the cause of the destruction. When this seductive poison, alcohol, is placed along the streets in saloons, men will take it. The fact of its being on the street is the real cause of its being taken. Irrespective of the question of the responsibility for its existence, the saloon is fundamentally an assassin.

When the true nature of alcohol becomes better understood, no community will longer tolerate these assassins who take their stand on the corners and

up and down the squares of our cities. In the premises the State has not only the right, but the bounden duty, to put an end to this wholesale assassination.

TREASURES ON EARTH AND TREASURES IN HEAVEN.

The clipping below was mailed us by A. F. Cowles, Swengel, Pa.:

Who is the God of this age?—II. COR. 4:5.

In 1907 there was paid in the United States for foreign missions, \$7,500,000; for drugs, \$27,500,000; for jewelry, \$60,500,000; for confectionery, \$128,000,000; for tobacco, \$949,500,000; for liquors, \$1,744,447,672.

How would it look to reverse these figures?

What do you think of the above, dear friends? and where are your own investments being made just now? Are they transient investments for this world only, or are they for time and eternity? Each one of us will have to answer for himself.

NO LIQUOR SOLD ON DINING-CARS IN THE STATE OF OHIO.

See the following, which we clip from the *Union Signal*:

NO MOVING SALOONS IN OHIO.

It is reported by the press that Attorney-General Hogan, of Ohio, has found that the constitution forbids a moving saloon, and has instructed the State Liquor Commission to issue no license to railroad companies to sell drinks on trains passing through Ohio.

WATER-DRINKING AN EXAGGERATED VIRTUE(?).

As might be expected, as the liquor men are crowded closer and closer into a corner they make desperate efforts to escape. The latest is that water-drinking is the cause of appendicitis. This discovery(?) was made in France; and the inference is that, if you drink wine instead of water, you will not have appendicitis. This piece of news comes from the *Providence Bulletin*. The concluding sentence is:

From these data the public is drawing the conclusion that total abstinence is an exaggerated virtue, even from a scientific point of view.

TOBACCO, CIGARETTES, ETC., AND THE HIGH COST OF LIVING.

An old friend just met me, and put out his hand, and said, "Mr. Root, it is just a year now since I used tobacco in any shape or form." Come to think of it, another friend said the same thing only a few days before, and these two men both agreed that they were feeling much better, mentally, physically, and morally. One of them spoke of his wife, and asked me how much it would help this trouble about the high cost of living if a few more would do as he had

done. He said it would help a big lot. He mentioned the names of friends of his who sometimes smoke toward a dozen high-priced cigars in a day. Do you suggest they can afford it? In one way perhaps they can. But how about the example it sets? How about the women and children who actually go hungry because the head of the home uses tobacco? Somebody away off sent me the newspaper clipping below. He did not give the name of the paper from which it was clipped, but it contains a splendid sentiment notwithstanding.

During the fiscal year 1912-13, 14,277,000,000 cigarettes and 7,700,000,000 cigars were burned by the American people. The Goddess of Liberty may have a fine statue, but there is more incense burned on the altar of My Lady Nicotine.

Next to the great Father above, we American people profess to be loyal to the Goddess of Liberty; but is there not a big truth right there? Are there not more of us who are really loyal to the Goddess of Nicotine than to the Goddess of Liberty? Very few fathers would be pleased to see their boys commencing to use tobacco. Am I not right about it? When we come to take the matter fairly and squarely and honestly into consideration, are there not still other higher and holier reasons for avoiding these things which certainly do us no good? How often I hear men say (and all kinds of men too), when they are discussing a man's value to the world and to the nation, after speaking of his other good qualities, "He does not swear, does not use strong drink," and finally they wind up by saying, "Why, he does not even use tobacco!" Is it not the general inference that the man who from principle has given up the use of tobacco has also given up almost every thing else that is bad and wrong, and ungentlemanly and ungodly? May God help us as a nation of people, not only to cut off the use of expensive things, but things that are positively harmful.

A CIGARETTE FIEND KILLS SEVEN PEOPLE; GAS-WELL KILLS SEVEN; EXPLODES WHEN CIGARETTE IS THROWN NEAR PIPE OUTLET.

TULSA, OKLA., July 24.—Seven men were killed and several others were probably fatally injured late to-day, when a gas-well exploded and caught fire at Lost City, about five miles west of Tulsa.

The explosion was caused by a cigarette stub dropped by a bystander, according to Stephen Snyder, son of a farmer living near the well, who was assisting the drillers, and was first of the injured brought to Tulsa.

Snyder is frightfully burned, and is not expected to live.

The above, clipped from the *Cleveland Plain Dealer*, is another illustration of the fact that the man or boy who smokes cigarettes is too stupid—at least oftentimes he is—to be permitted to run at large.

Gleanings in Bee Culture

NO. 23

Editorial

REPORTS of extremely warm weather are coming in from all parts of the country. The danger will be that stores will be used up rapidly in brood-rearing. Beekeepers will do well to see that their colonies do not starve before spring.

ON page 20 of the advertising section of this issue will be found a letter from N. E. France that will explain itself. He has distributed something over 35,000 books on "Honey as a Food," and now has exhausted the supply as well as his funds.

E. R. ROOT expects to make a demonstration in the use of modern extracting machinery, including a power extractor, honey-pump, steam knife, and a capping-melter, at Des Moines, Iowa, on the afternoon of Dec. 11. This means, of course, that he will be present at the Des Moines convention Dec. 10, 11, and 12. For full program see Convention Notices on page 20 of our advertising section.

DONAHEY, THE CARTOONIST, A BEEKEEPER.

THE clever cartoonist of the *Cleveland Plain Dealer*, Mr. J. H. Donahey, has been a beekeeper on a small scale for several years. This year he enlarged his apiary somewhat and his interest has increased in proportion. Quite frequently his cartoons show the beekeeper or the bees, and of late he has begun to write an occasional article (signed "Uncle Biff") on the care of bees, or on some topic closely related.

Mr. Donahey is a cartoonist whose work attracts the widest attention, and he has already made his reputation along that line. Who knows but that some day he may also make a reputation for himself as a professional beekeeper? He has a good start.

OUR FRONT COVER PICTURE.

THE front cover of this issue shows the apiary of Mr. Earl M. Nichols, of Lyonsville, Mass. This apiary has the honor of holding the first Langstroth hive that was ever made. Earl M. Nichols himself is sitting in the very spot, as nearly as it can be

located, where Mr. Langstroth put his first movable-frame hive. In this connection (see p. 853) the reader will be interested in some history concerning W. W. Cary and father Langstroth; and perhaps he may derive some pleasure in looking at the old original building where the first Langstroth hive was made.

HONEY DAY IN INDIANA; A SCHEME TO BOOST THE SALE OF HONEY.

IN our last issue, under the head of Convention Notices, in the advertising section, page 18, we inserted an announcement to the effect that Indiana was to observe "honey day" Dec. 15. Mr. G. W. Williams, Redkey, Ind., Secretary of the Indiana State Beekeepers' Association, seems to be the man who is pushing this general scheme. He is prepared to furnish write-ups for the local papers, and, in addition, large display cards 7 x 11, to put up in groceries, calling attention to honey day, and asking everybody to eat a little honey. He has also sent circular letters to the secretaries of the various State beekeepers' associations of the country, urging upon them the introduction of a plan similar to this in their own States. The idea is, of course, to induce a larger consumption of honey, not only in Indiana, but throughout the country. A little effort on the part of beekeepers will do much toward calling attention to the value of honey as a food; and once consumers get a little of the honey habit they will keep it up.

A NEW MOVING-PICTURE FILM ON BEES.

SOME time last summer the Bureau of Entomology sent Dr. E. F. Phillips and a moving-picture photographer to Medina to catch some scenes of bees in action. A number of pictures had been taken at the government apiary, but Dr. Phillips desired some additional scenes which he could get at a large apiary. The two men spent a couple of days at Medina, during which time they secured some very fine pictures of our men and bees in action. There is a fine picture of a swarm clustering on a tree, and the means taken for hiving the same; a view

of a swarm rushing from a hive pellmell; one showing the various manipulations connected with extracting, using an eight-frame power-driven extractor, a capping-melter, and a steam uncapping-knife, and still another showing the handling of live bees. These and numerous other tricks of the trade were taken.

This film has now been released for the public, and is being shown at some of the principal moving-picture theaters in the country. We have been told by those who have seen it that it is an extraordinarily good one.

We suggest that our readers apply to theaters using Universal films, and ask to have this shown. It is a fine film, and will do not a little to educate the public in regard to the kind of work that is carried on in an ordinary beeyard, and, what is more, will advertise honey by showing how it is taken from the bees by modern methods.

THE SAFE ARRIVAL OF THAT CAR OF BEES TO FLORIDA.

THAT carload of 300 colonies of bees that we started on the 14th of November reached its destination at Ranlett's Landing, on the Apalachicola River, Fla., just one week later—namely, the 21st. Every thing worked out exactly as per schedule. This quick trip could not have been accomplished except by careful planning in advance. We personally visited the general freight agents of the principal lines over which the bees were to go. We explained that this was something of an experiment, and that, if it worked out favorably, we could do a greater business of the kind in the future. We told them stories about bees, and left with them samples of honey. It is wonderful what a little honey will do when applied at the right time and in the right way. The railroad people became very much interested, and promised to get that car through on fast freight trains.

The bees were loaded into an ordinary fruit-car with a door at each end and at each side. Unfortunately the weather turned very warm after the blizzard. But the hives were arranged so as to secure plenty of ventilation by opening the front and rear as well as the side doors. In spite of the hot weather for almost the entire journey the bees arrived at destination in good condition. Along with this carload of bees was another carload of bee-supplies—enough to make 600 hives more with frames of foundation. We aim to increase this 600 to 900, but may hardly reach that figure. If conditions are favorable for pollen and nectar we ought to be able to do it. If so, we shall

then load the bees into three cattle-cars and send them back north. So far our program has worked out according to schedule. It remains to be seen now what the future will develop.

THE PURE-FOOD LAW AS IT RELATES TO OHIO.

A SHORT time ago we had occasion to send an inquiry from one of our customers to the office of the Dairy and Food Commissioner of Ohio. The nature of the inquiry will be understood by the reply.

Mr. Root:—We have received your letter of the 10th and the enclosed copy of a letter from one of your subscribers inquiring about the labeling of honey. Complying with your request for a reply concerning the labeling of foods for publication, we are pleased to suggest the following:

Section 5774 of the General Code of Ohio says that no person within this State shall ***** offer for sale, sell, or deliver, or have in his possession with intent to sell or deliver, a drug or article of food or drink which is misbranded within the meaning of this chapter.

Section 5785 defines what shall constitute a misbranding of a food product: 1. If the package fails to bear a statement on the label of the quantity or proportion of morphine and other habit-forming drugs or any derivative of such contained in any food preparation; 2. If it is labeled or branded so as to deceive or mislead the purchaser, or purports to be a foreign product when not so; 3. If in package form, and the contents are stated in terms of weights and measures, if they are not plainly and correctly stamped on the outside of the package, 4. In case of a flavoring extract for which no standard exists, if it is not labeled "artificial" or "imitation," and the formula printed in the manner hereinafter provided for the labeling of "compounds" and "mixtures with their formulæ;" 5. If the package containing it, or a label thereon bears a statement, design, or device regarding it, or an ingredient or substance contained therein, which is false or misleading in any particular. This section then contains an exception clause which says that the section shall not apply to mixtures or compounds recognized as ordinary articles or ingredients of articles of food or drink, if each package is distinctly labeled in words of the English language as mixture, or compound with the names and percentage, in terms of one hundred per cent of each ingredient therein. The section closes with a statement of the size of type to be used in printing the formulæ, and with the statement that such compounds or mixtures must not contain an ingredient that is poisonous or injurious to health.

The sole purpose of the adulterating and misbranding law is to prevent the sale of adulterated and misbranded foods and drugs; in other words, to prevent fraud and deception, and to protect the lives and health of the people.

There is nothing in the law requiring an absolutely pure article of food to be labeled. It is much better, however, for all concerned that all articles, whether containing but a single pure ingredient, or articles known as mixtures or compounds containing several ingredients shall be labeled with the name of the article and the name and the address of the manufacturer or producer. Labels are inexpensive, and the manufacturer or producer shows an evidence of good faith when food products which he offers for sale are so labeled.

All products which contain habit-forming drugs, or which are mixtures or compounds within the meaning of the law, must bear labels stating such facts.

Briefly, then, the law does not distinctly say that articles of food must all be labeled; but the law does say that if articles of food are mixtures or compounds, or contain certain drugs, such articles must be labeled with a true statement of the facts.

Columbus, Ohio, Oct. 13.

S. E. STRODE.

CRACKED-WHEAT MUFFINS AND HONEY; A SOLUTION OF THE PROBLEM OF THE HIGH COST OF LIVING.

LAST summer, on page 514, of our issue for Aug. 15th, we spoke of the pleasure we had in eating a home-made cereal sweetened with honey. This cereal is certainly the cheapest thing of the kind in the world. It will go a long way toward solving the problem of the high cost of living, because it is almost a complete food of itself. It is nothing more nor less than ordinary wheat run through a family hand grinder such as can be obtained at any of the large hardware stores, particularly Montgomery Ward & Co. or Sears, Roebuck & Co., of Chicago. The mill is set so that the wheat is not ground fine; and when ground and cooked for 4 hours over a slow fire it makes a most delicious breakfast food in connection with a little extracted honey. The fact that it is ground coarse makes it all the more valuable to persons of sedentary habits, especially if they find it necessary to use cathartics at times. Referring to the muffins made from this cracked wheat, one of our subscribers along last summer sent the following inquiry, which was overlooked. He writes:

We feel interested in what you say about the above, but we shall have to ask you to make the recipe more intelligible. We have cups here in the South that will hold anywhere from a gill to three quarts. It may be that the people living north of the Ohio River understand what is meant when you say a cupful, but not many of us south of it would readily understand it.

Reidsville, N. C., Aug. 20.

JAS. M. GIBBS.

By a "cupful" we mean a common tea-cup holding half a pint. As some may have mislaid our Aug. 15th number, we are reproducing the recipe here.

Two cups whole-wheat flour; 1 tablespoonful white flour; $\frac{1}{2}$ teaspoonful salt; $\frac{1}{4}$ cup sugar; 2 eggs; 1 cup sour milk or buttermilk; $\frac{1}{4}$ teaspoonful soda; 1 tablespoonful melted butter.

At our house this kind of graham muffins is preferred by nearly all the members of the family to white bread, not alone because they are superior in food value, but because they are toothsome and delightful.

Ordinary wheat is now worth 90 cents per bushel in our locality. With a hand grinder one can grind up his own cereal as he needs it, a little at a time, in order to avoid its becoming wormy; and this is one reason why cereal foods are so high in price generally. They have to be put up in pound

packages, and these, of course, add to the price of their contents. Another large item entering into their cost is the advertising that appears in all the periodicals. This kind of overhead expense alone must necessarily double the cost of the food after it leaves the mill. But this cracked wheat can be had at practically the price of raw wheat per bushel because it carries with it no overhead expense; and it has as much or more food value than any of the cereals sold, at a small part of their cost.

During these winter months granulated extracted honey and cracked-wheat cereal or muffins make a menu that is fit for the gods. If they are prepared right they are more toothsome than any of the modern cereals whose praises are sung in every magazine in the country, and at a mere fraction of the cost.

Beekeepers who have honey for sale would do well to call the attention of their customers to the cheapness of cracked wheat as a cereal, at the same time explaining how well extracted honey goes with it.

THE TORONTO CONVENTION.

WE have just come from attending a very enthusiastic and successful meeting of the Ontario Beekeepers' Association held in Toronto, Nov. 19 to 21 inclusive. When we arrived at the convention hall we were not a little surprised to see so large an attendance. It was estimated that there were 350 present. This is larger than the attendance at conventions that have been held on this side of the line. Indeed, there have been only two meetings in this country, if we are correct, that surpassed it. One was the National, held at the World's Fair, Chicago, and the other the field-day meet at Jenkintown, Pa. But one feature peculiar to the Toronto convention was the fact that there was so large a number of extensive honey-producers who could measure their crops by the earload.

In this connection it is proper to remark that Ontario probably produces a larger amount of honey, and table honey at that, than any State in the American Union, even if we include Texas or California. The soil conditions just north of the lakes are superior to those just south of the lakes. The whole of Ontario seems to be a splendid fruit and bee country; for, so far as we can ascertain, the territory is well developed; or, to put it another way, it is but fair for us to say that more beekeepers probably could not be accommodated in the Province without overstocking, so that there is no use for beekeepers on this side of the line to migrate over into Ontario, as they will find

the country well stocked with bees and beekeepers.

But why so large an attendance? In the first place, the area of good bee country is very compact. The beekeepers would not have to go so far as they do in this country. But this alone would not explain so large a number of persons present. The secret really lay in the active work done by the secretary, Prof. Morley Pettit, Provincial Apiarist, located at the Agricultural College, Guelph, Ontario. For over a year back, he has been working to secure membership for the Association, with the result that he has doubled and trebled it; and now Ontario has something like 1400 members on its roll. We asked him how he secured so large a number. He replied, "By advertising." He kept at work at the local associations to get the members to affiliate with the Provincial organization, and to a large extent they have done this. It was not so surprising, therefore, that delegates from all over the Province were present, making something like 350 on Nov. 20, forenoon and afternoon.

We have always entertained the belief that the clover honey of Ontario was of a very superior quality. The extracted, this year at least, is several shades lighter than the same honey south of the lakes. One reason of this is that the Canada thistle, which is usually present in clover, furnishes a very superior honey. It is very light in color, and when blended with clover makes an article that is to all intents and purposes a water-white, or as near as any honey ever gets.

SNOW AN EXCELLENT PROTECTION FOR OUT-
DOOR-WINTERED COLONIES; IS THERE
DANGER OF ITS BEING TOO MUCH OF
A GOOD THING SOMETIMES?

MEDINA was in the snow-blizzard area of the Northern States that swept the central section of the country on the 9th and 10th of November. Such a blizzard, in this locality at least, was fully two months ahead of time. We were enveloped in snow to an average depth of two feet on the level to eight and twelve in drifts. The result was that our outdoor colonies, which we were expecting on the 10th to load into a car for Florida, were buried in many cases out of sight. It was not particularly cold—about 32 degrees all the time—and the snow was a splendid protection; but it was a little damp when it fell; and when the weather turned a little colder on the 11th the snow began to cake, and then we began to fear trouble. By digging down to some of the colonies we found that some of them were

suffering from want of air, and doubtless many would have died if we had not provided ventilation. Examination showed that the hot breath of the bees had melted the snow for quite a space around the entrance. In some cases the water from the snow froze, filling the entrance up completely, and, of course, the bees became uneasy. But, fortunately, we caught them in time.

Fuller particulars will be given, with a series of photos showing the result of the snow blizzard at Medina; but for the present, at least, it is proper to anticipate a question that may arise in the minds of a good many of our readers, as to whether there is much danger of bees suffocating under the snow. This question we have already answered in part, and it only remains for us to say that a light snow drifted around the hives, so far from being harmful, is beneficial; but when it drifts over the tops of the hives, thaws a little and freezes, there is danger of suffocation. An ordinary light snow, even when drifted over the hives, will do no harm for a few days; but such hives should not be left too long.

It will not be sufficient to run a board or a stick down to the entrance in case the hives are deeply buried, for the simple reason that such a procedure will not disclose the fact that the entrance may be closed with ice. For example, we ran a stick down and made a wide opening at the entrances of several hives, on the 10th. After this was done, Mr. Marchant thought he would investigate. He did so, and found that some of the entrances were clogged with ice. The only thing he could do was to use a shovel, and run his hand down and feel with his fingers in order to ascertain if the entrances were open—a procedure, by the way, not particularly comfortable.

In 1881, at the close of March and opening of April, we had a three-days' blizzard of snow. At that time the hives were buried clear out of sight. Naturally enough we supposed that this snow would be a good thing; but that spring recorded the most fearful mortality among outdoor-wintered bees that was ever known in all modern beekeeping. At all events, our own loss was the greatest we have ever had, and the complaints from all parts of the North showed the same heavy losses. Prior to that time, and even after it, our own winter losses had not exceeded five per cent, and usually did not go above two per cent. We are coming to believe more and more that the bees that year suffered more for want of ventilation on account of the entrances being closed with ice than because of the extreme cold that then prevailed.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

F. A. GRAY sends me a sample of his fall honey which he says is almost all sugar; and as he fed no sugar he wants to know the source of the honey. My guess is that it is a good grade of honey-dew that has candied. I'm forwarding the sample to ye editor. [After examining the sample we should unhesitatingly confirm Dr. Miller's opinion that it was a good grade of honey-dew.—Ed.]

D. F. COY is in the sweet-clover region that surrounds Chicago. In 44 days, beginning July 7, his best colony stored 188 sections of sweet-clover honey. A daily average of $4\frac{1}{4}$ sections for 44 days shows sweet clover a good yielder in that case. Mr. Coy depends chiefly on sweet clover for his surplus. It is a long yielder, but the honey has a greenish tinge, and does not present as fine an appearance as white-clover honey.

LOUIS MACEY, p. 771, please don't paint in too dark colors the evils of sending queens by mail. Of the queens I've had by mail, the great majority have done good work and lived the usual span. Nevertheless your suggestions are well worth considering, and in answer to your question I may say that E. R. *has been* sending queens in packages of bees. [Young queens will stand a journey through the mails much better than older ones. Experience shows that old queens or breeding queens, six months or a year old, do not stand the journey as well as a young queen that has just begun to lay. It is right here that baby nuclei have one advantage in that the queens can lay only a few eggs by the time they are packed off in the mails. Yes, sir'e; as a general rule pound packages of bees contain a queen.—Ed.]

M. A. GILL is level-headed in that article, p. 770, but one point will bear comment. He says: "It matters not how slipshod the methods are that produce a can of extracted honey. If it is ripened—" "Ay, there's the rub"—if it is ripened. But that's just the thing most likely not to be, if slipshod methods are used. And right there is the spot where Mr. Slipshod is likely to do twice as much damage to the reputation of honey with extracted as with comb. He may do his worst with comb, and the consumer may be disgusted with the appearance of his product, covered with bee-glue and travel-stain; but the next time he sees a sample of comb honey like Gill's he's just as ready to grab for it as if he'd never seen Slipshod's. Not so if he has had some of Slipshod's unripe extracted. It makes him

suspicious of all honey; and *seeing* a sample of best extracted doesn't remove that suspicion, as in the case of comb honey. Quite right, Bro. Gill; your motto, "Not how much, but how well," is the motto for producers of comb honey, and doubly so for producers of extracted honey.

J. L. BYER says, p. 670, "For 'our locality,' 'bees always strong' is the only safe rule if best results are to be obtained, and I never fret about bees being reared out of season." Same here, friend Byer. I don't believe there's ever a time when I would gain to restrict brood-rearing except for two causes—swarming fever and foul brood. On the other hand, I don't believe there's ever a time when I can profitably do any thing to favor brood-rearing except two things: To keep bees snug and warm, and to see that they have *abundance* of stores.

There may be localities or strains of bees where at times brood-rearing should be discouraged; but I suspect that's the exception and not the rule. There are, no doubt, places or bees where brood-rearing would stop entirely if the beekeeper didn't interfere; but I suspect they are the exception. I don't believe I ever gained by stimulative feeding, and I'm sure I've lost by spreading brood. If my bees rear all the brood they can cover (and they do), what more would you have?

It may be all right to haul bees without fastening in hives, say 19 times out of 20; but after some experience I've had with bees getting out when supposed to be fastened in, you don't hire me to haul them without fastening—not with horse power. [There is one point, perhaps, in this that you have overlooked. A colony of bees that is shut in a hive by means of a wire cloth is often in a state of excitement on account of the confinement and lack of air. The minute that the wire cloth breaks loose *en route*, they may rush out like a lot of mad hornets and sting viciously. If, on the other hand, that same colony had not had its entrance closed up, and were given a little smoke at the entrance before it was closed, it would remain quiet during the entire journey. A few bees will sometimes crawl out of the entrance; but the initial smoking and subsequent jolting will put bees on their good behavior. If short of air they will crawl out of the entrance, where they will seldom do any harm; and if hauled in an automobile truck and they should sting, they will cause no trouble—at least not a tip-over.—Ed.]

Beekeeping Among the Rockies

WESLEY FOSTER, Boulder, Col.

Have you ever noticed that exposed honey just off the hives will attract robbers much sooner than honey that has lost the hive warmth? The odor given off is much less pronounced from honey that has cooled off.

CLIMATIC CONDITIONS CAUSE VARIATION IN COLOR OF HONEY.

Mr. P. C. Chadwick says, Oct. 1, p. 671, that every form of nature follows its law—each form on the line on which it was created, and that each one follows only the line given it. In the first place, we mortals don't know definitely the laws governing every form of nature, as there are so many of them. Flowers and plants are undergoing a constant change. No two plants are the same under different conditions. They adapt themselves to environment the same as do people. So it may be safely stated that one of the fundamental laws of nature is change and variation. I think that we have very good evidence here in Colorado to prove that flowers secrete nectar under varying conditions of climate, and have different colors as well as qualities. I do not know what color alfalfa honey has in California; but I do know that we have white alfalfa honey in Colorado in many districts. I think I shall have to set Mr. Chadwick's twenty-five years of observation at naught and state that honey changes with the wind, moon, and soil conditions. The various honeys such as alfalfa, orange, white clover, and basswood, however, *approximate* a certain definite standard. I am satisfied that alfalfa honey will vary from white to light amber in color, and in body from light to heavy. Whether the atmosphere or the food Mr. Chadwick eats has any effect on the color of his blood, I will not say, but it is an accepted fact that climate has an effect on the color of people's skin, hair, eyes, etc. People on the Pacific coast have a different complexion from those in the Rocky Mountain region. "Nothing is permanent but change." [There can be no question but that the color of alfalfa honey (and this is true of other honeys) is dependent somewhat on the locality in which it is produced. The buyers have ample proof of this.—Ed.]

COMB HONEY OR EXTRACTED HONEY.

The beekeepers of the West have had a hard proposition to face in the last few months. The price secured for comb honey, which is the kind largely produced in Colorado, has fallen from ten to fifteen per cent below the price secured last year. Bee supplies have gone up about ten per cent. This

lessening in prices secured for honey, and advance in supplies, is going to bring about important changes in beekeeping throughout the West. It is going to put a damper on beekeeping by those who have depended upon it for a living. This effect will not be apparent at first. Another effect of the lower prices secured for comb honey and the raise in the price of supplies will be the turning to extracted-honey production. Extracted honey will bring the Western beekeepers almost as much as his comb brought this year if he seeks his own market and develops it. Extracted honey can be raised with a much smaller outfit of supplies. There are many Western honey men who confine their efforts entirely to extracted honey, who have practically no outlay for supplies, while the comb-honey men will have to expend several hundred dollars each year for sections and foundation, and as much more for shipping cases. The home market in Colorado (and probably in other States to the south and west) does not consume more than ten per cent of the total production. This should be and will be increased; but it is doubtful whether the home consumption will equal the production for many years. There are too many towns of two or three hundred population where several cars of honey are shipped annually. [An enormous crop of clover honey was produced east of the Mississippi last season. As much of the Western honey finds its market in the East, the severe competition of the Eastern honey this season would necessarily affect prices on the Western. Prices, however, next year should resume their normal, as it is hardly probable that there will be another as heavy a yield of clover honey in 1914, if the law of average holds good.—Ed.]

TREATMENT OF SAC BROOD IN MINNESOTA.

Mr. J. Alf Holmberg, apiary inspector in Minnesota, recommends treating sac brood where there are not too many colonies affected. He reports a yield of 75 lbs. from a diseased colony so treated. It may be that sac brood is more destructive in Minnesota than in Colorado, but I have had scores of colonies affected that produced over a hundred pounds of comb honey each, and they were not treated, the disease disappearing, or practically so, before the season was over. If but a very few colonies are found affected in a locality it might be well to treat all affected ones, if treatment will cure the trouble; but we have so many

colonies affected that we pay no attention to it, and it causes very little trouble except in a very few cases.

Mr. Holmberg mentions carelessness in treating foul brood. Carelessness is so prevalent among beemen in handling foul brood that it is better to burn every thing diseased if but a few colonies are found. Not long ago, in company with one of our county apiary inspectors, I was going the rounds on reinspection work to see how well diseased apiaries were cleaned up. We came upon one alert young fruit-grower who had about twenty colonies, and among them a few cases of disease. He had the government bulletins, and had studied them, especially the one on "Treatment of Bee Diseases," by Dr. Phillips. He had invested in a gasoline-torch for disinfecting, and was following disinfection directions to the letter; but it was right at the close of the honey-flow, and an hour earlier he had been called to dinner, leaving a diseased colony untreated with the hive cover off, which he had forgotten to put on. We came in time to find a nice case of robbing going on while he was out at the honey-house disinfecting hive-bodies with the blue-flame torch! He undoubtedly profited by the experience, and I mention the instance, thinking that it may be helpful to some other earnest young beekeeper.

MUCH PUSHING NECESSARY TO SECURE FOUL-BROOD LEGISLATION AND APPROPRIATIONS.

It is unfortunate that we did not secure an appropriation for bee inspection, as the law enacted is such a worthy one for the control of bee diseases. Prof. Wilmon Newell, with his corps of inspectors, was ready to do effective work. It should not be left with the chief inspector to secure legislation for beekeepers. The State and local associations should work hand in hand in this work. The writer, who is deputy bee inspector in Colorado, under C. P. Gillette, State Entomologist of Colorado, had considerable to do with securing Colorado's law for bee inspection with an appropriation to carry on the work; but the real test always has come when the bill is in the hands of the finance committee of the Senate. The experience in securing the last law will illustrate well what work needs to be done. The bill had been drawn up and introduced by Hon. O. C. Skinner, who was speaker of the last House of Representatives. Mr. Skinner was at that time and is yet a beekeeper, owning several hundred colonies. He is an active member of the Montrose Beekeepers' Association. Mr. Skinner introduced the bill in the house, and his colleague, Senator Tobin, of Montrose County, introduced the bill in the Senate.

Mr. Skinner told me, when I took the bill to him to be introduced, that there probably would be some difficulty in getting it passed, as it carried an appropriation of \$2500 annually, but he said that with hard work we could probably get it through.

The beekeepers over the State were urged to write their legislators, and most of them were furnished with the names of their own legislators in case they might not know who their own representatives were. The beekeepers were also urged to write to the Governor. Governor Ammons is a farmer and stockman himself, and is vitally interested in building up the agricultural interests of Colorado. In answering my letter, asking him to do what he could for the bill, he wrote me that he would sign it, and, furthermore, stated that he would do all he could to get it reported out favorably by the finance committee. This I think he did; but the finance committee had decided to let this bill die a natural death in one of their pigeonholes, along with many other bills. About this time Prof. Gillette wrote me that he doubted very much whether we could secure any legislation carrying an appropriation, as the legislature was determined to pass no new bills carrying appropriations.

I went to the telegraph office and sent five or six telegrams to the presidents and secretaries of our local beekeepers' associations over the State, and urged them to send telegrams to their representatives and senators. I know that nearly all of these beekeepers did this. Mr. J. C. Matthews, of Montrose, sent a telegram to Senator Tobin, and also to Mr. Skinner, I believe. Now, Mr. Tobin went to the finance committee and told them that he had come for that bill, and expected that it would be reported out favorably, and he stayed until he got the bill reported. But we didn't get the full \$2500 annual appropriation. It was cut to \$1500 annually. The Governor signed the bill as passed by the legislature, and now the law is in effect.

The beekeepers, if they will all stand together and work hard at the right time, can secure worthy recognition of their industry. The organization of the campaign is the important part. There must be a leader, who should be one of the officers of the State Beekeepers' Association, who will keep the mails hot telling the beekeepers when to write, and offering suggestions as to what arguments to make. [Mr. Foster is exactly right. If Entomologist Newell, of Texas, had had the support of the beekeepers of his State, as did Professor Gillette, of Colorado, there would have been no lack of an appropriation.—ED.]

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

Hard by the garage grew a rose,
Wind-tossed with stem atilt.

One night, unseen,
A chauffeur mean
Some petrol on it spilt.
Adulterated rose nectar
A bee did sip next morn,
And now it does
No longer buzz

But toots just like a horn.

Some friend in Toronto sent me the above clipping pasted to a postal card.

* * *

Moving bees without closing the entrances is all right for the man who understands his business and is either doing the work all alone or is able to get help thoroughly reliable and capable. Without these conditions it is a risky business, and I advise beginners to close all entrances bee-tight with wire cloth. Of course, in hot weather abundant top ventilation will be necessary too, to avoid suffocation.

* * *

As one of the conditions for fast work in extracting honey, it is stated on page 776, "If frames are spaced $1\frac{3}{8}$ from center to center." To my notion that would be a factor to retard rather than help; and if they were spaced more like $1\frac{3}{4}$ than $1\frac{3}{8}$, things would go much faster, especially after combs are in the honey-house. Wide spacing of extracting-combs is an economizer in more than one way, and it is a practice fast coming into use among many producers who were formerly opposed to the plan. Once try it, and I venture to say that not one in a hundred will return to the old plan of close spacing.

* * *

According to your dictum, Mr. Editor, p. 746, Nov. 1, a great many communities ought to be left out in the cold because the majority of places still have not the gump-tion to have roads good all the year round. But we are gradually coming to the point where people see the necessity of good roads, and at present there is more agitation along this line than ever before. Some say that the auto owners are behind these good-road schemes for selfish purposes; and while there may be something in this contention, yet for once, at least, let it be said that selfishness (?) will be good for all classes of the community.

* * *

E. D. Townsend says that "alsike clover is the future dependence of Michigan for its honey supply." In many respects Michigan must be a great deal like Ontario, as the same statement would largely apply to

this Province, comparing one year with another. While there are many localities where white clover yields a good surplus some years, generally speaking "white-clover honey" is a misnomer, as I believe that three-fourths of the clover honey of Ontario is annually gathered from alsike. Certain it is, that, if one hears a beekeeper asking about a prospective location, invariably the question comes up, "How is it for alsike?"

THE CONVENTION IN TORONTO.

These notes are being written just ten days before the date of our annual convention in Toronto, and indications point to a record attendance. The date is a week later than other years, and this means that most beekeepers will be through with the rush of the work for the season. Personally I am looking forward to this annual meeting with a thrill of pleasure. While I always get something of value from the program, yet after all I plead guilty to being actuated more by the social instinct than any thing else; and I just wonder if there are not many others with the same weakness. After all, what would life amount to if only *dollars and cents* were all one had to take pleasure from? Show me a man with just that predominating passion, and you may be sure he is a source of pleasure to no one else—possibly not even to his own selfish nature.

TOBACCO SMOKE FOR BEES.

Arthur C. Miller says that Henry Alley never advised tobacco smoke for introducing queens to full colonies. Never mind whether he did or not; yet many beekeepers have used that plan scores of times, this scribbler among the number. But, thanks to friend Miller, I find, so far as I have experimented with the plan, that ordinary smoke from any thing used commonly as a smoker fuel will answer the same purpose as the tobacco. This saves buying the tobacco and saves me from getting sick, as has already happened when I seemingly got more than the bees did. Come to think of it, quite a few times I have seen bees rolling out from the entrance when smoked with tobacco, so Mr. Miller's plan saves *bees* from getting sick too. I just wonder if it would be wrong to wish that tobacco would make *every thing sick* that uses it. I suppose the matter is none of my business; but I am led to make this query because of a number of good friends of mine who have repeatedly told me that they wished they could quit using the "stuff." You see, if it made them sick *enough* their wish would be fulfilled all right.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

In the issue for Nov. 1, p. 754, Mr. Doolittle recommends the use of open entrances in moving bees. Editor Root also comments on the plan. Mr. L. L. Andrews, of Corona, who has had a wide experience in this line, left the impression with me last spring that he had not found the plan satisfactory. There is one very great objection that I see in a locality where there is liable to be foul brood, or where it is known to be prevalent; that is, the danger of spreading the disease to the four winds. Personally I think the plan should be discouraged, as there is too much risk in this connection.

CLEANLINESS IN EXTRACTED-HONEY PRODUCTION.

Nov. 1, p. 770, Mr. M. A. Gill has an interesting article. Much of it is good, but a part of it I do not feel like letting pass without comment. I have very great respect for the opinion of such a man as friend Gill, for these old timers with years of experience deserve the place they hold in the esteem of the beekeeping public. Yet there are some things in this article which do not sound fair to those who produce extracted honey. I quote the following: "Now, if a campaign is to be started urging the production of more comb honey, let's first start a school urging the placing of a better grade on the market." That part is right; but why stop with comb honey? Such a school is needed in the extracting line just as much as it is needed for a better grade of comb honey. Mr. Gill also says, "It matters not how slipshod the methods are that produce a can of extracted honey. If it is ripened, settled, or properly strained, it is all right for market, and anybody who can turn a grindstone can produce extracted honey whether at a profit or not." Is it not true, also, that those who could turn the same stone can produce comb honey? I think the rule would apply equally in either case. Mr. Gill's comparison is hardly fair to those who take pride in producing a fine grade of the extracted product. A beekeeper who is inclined to be neat and painstaking in his work would in all probability do just as well, so far as producing a fine article is concerned, with comb honey as with extracted. I fail to see why all of the careless and slovenly inclined should be uninstructed and allowed to continue to produce a poor article of extracted honey while those producing comb honey were being instructed in producing comb. A good, clean, well-ripened, neatly packed package of ex-

tracted honey is just as important as is the same in comb. The tendency to be dirty is greater among producers of extracted than comb honey, because the faults do not show so plainly on the face of the business; yet there is all the more reason for care and for the discouragement of unclean ways. Neither can I agree that extracted honey, merely because the ants, larvæ, and dirt are strained out, and the honey is put in second-hand cans and a weather-stained case, is right for market.

I quote the following from an editorial in the November issue of the *American Bee Journal*: "I have just received a letter from Mr. J. F. Diemer, of Liberty, Mo., in which he states that he purchased some honey from a commission house. The honey was put up in 60-lb. cans, which were bright enough on the outside; but from the sample of tin sent us, they were about the worst ever on the inside. Mr. Diemer stated that, besides the rusty cans, there were so many bees, etc., in the honey that it was easy to tell that the producer was one who leaned toward black bees rather than Italians." Further on in the same editorial the editor does not altogether discourage the use of second-hand cans. Here is a sample of not only a dirty mess of honey, but also of one put up in a second-class manner, and yet the practice of using such second-hand methods is not altogether discouraged. To be sure, the honey in question was not properly strained; but even if it had been it could not have been first-class when packed in second-hand receptacles. If I had my way about the matter I would not permit the reuse of any can that had once been on the market; and I firmly believe it would be a good move for producers if they would adopt a can that could not be opened without destroying it for future use. Why dealers should be permitted to salvage these old cans, and turn them back to a class who are not overly particular about either the receptacle used nor the manner in which the product is put up, I can not see; for, as a rule, that is the only class of men who would care to allow their produce to be packed in such a manner. I have never used a second-hand can except when the purchaser had returned one to be filled of his own accord. I am perfectly willing to help Bro. Gill with his school if he will give a class for producers of every kind of honey on the market. But even at that, those who are not inclined to be tidy will fall more or less into the old rut.

Conversations with Doolittle

At Borodino, New York.

UNPAINTED HIVES WITH SHADE-BOARDS.

"I am in a quandary as to whether to paint the hives I am planning to build this winter. I suppose you read what Dr. Miller and Editor Root have to say on this painting matter, pages 400 and 401, June 15."

If Dr. Miller had not "fallen down" so easily he could have found that "weak spot" so as to give the last telling "jab" at the editor; for, unless locality has much to do with the matter, the editor's question, "Is it not true that an unpainted hive assumes a gray-black hue—a color that becomes almost pure black?" has no foundation, at least not in Central New York. Here, unpainted wood, if exposed to the weather, slowly changes to a light gray, or dull whitish tint, through the formation of a slight fuzz all over the exposed surface. In localities where wasps and hornets abound, this fuzz is scraped off with the mandibles of these insects, and used, when mixed with their saliva, to form their nests. I have yet to see a wasp's or hornet's nest of a gray-black or black hue. Now, where does this apply? This light-gray fuzz so "tangles up" the rays of the sun by the air circulating through it that it is almost cool in comparison with a hive which is painted venetian red, and compares very favorably with the hive which is painted white. With the experience of placing my bare hand on the surfaces of hives of different colors, scores of times during the past, I am at a loss to know how any unpainted hive which had been left out in the weather for a period of four or more years could be "almost hot enough to blister the hand." I had scores of combs melted down in hives painted in dark colors when I used to paint my hives, but never a comb in an unpainted hive, nor in one painted white. So if I were to paint hives, white would be the only color I would use.

But after seeing water running out from the entrances of painted hives on cool spring mornings when the bees were evaporating nectar gathered the day before, and after having combs mold to a far greater degree during the winter in all painted hives, while the combs and inside of the hives which were unpainted continued in far better shape, I decided, some twenty-five years ago, never to paint another hive.

As to the economy of painting, I consider it a myth. The editor cites the painting of houses to prove his ground. Last week I was told that a house two miles from here, which was built and the siding put on 87

years ago, had been torn down to give place to a modern house. As this old house had never been painted, I went over to see the siding. I found many of the boards almost as good as when put on. Others were cracked and checked at the ends and in different places, with a few somewhat decayed around the nails which had held them in place, while all were worn from one-third to two-thirds down or through by the storms beating upon them, except the lap, under which most of them were as sound as ever. Why talk about the economy in painting houses? The owner said that old house had not leaked through the siding since he bought the place, twenty years ago. The main reason for painting either houses or hives is the looks. If the looks keep a man interested and contented with his home or his bees when he otherwise would make "shipwreck" of either or both, with such a *one*, painting certainly pays; but where any man or woman can keep up the same interest in bees, and keep them in unpainted hives, my experience proves that more "dollars" will come to such a one than would accrue where the hives are painted.

But whether painted or unpainted, all hives should have shade-boards. These are "miles" ahead of shade from trees or buildings for bees, and for profit from an apiary as well. I am surprised to note that Dr. M. uses painted tin covers, or those having the wood covered with zinc. Either keeps the moisture in nearly as badly as does paint. Leave the wood cover without paint, doctor, and put the zinc over the shade-board. I make a "skeleton" of $\frac{7}{8}$ -inch-square strips, as wide as the cover of the hive, and eight inches longer than the hive is as it stands with the entrance to the south. I raise the back or north end of the skeleton four to six inches from the cover by means of posts or legs. This allows air to pass over the cover, and carries off the rain. To the top of the skeleton I nail $\frac{3}{8}$ or $\frac{1}{2}$ inch lumber one foot longer than the cover of the hive is wide. I cover this with zinc, tin, or two-ply balkan roofing paper. The latter answers all practical purposes, and costs only 75 cents for a roll which will cover 108 square feet. The tin and paper need paint to keep them from deteriorating. The thin lumber can be obtained from boxes in the country store, at a cost of little more than a song. When nailing to the skeleton, allow the foot an extra length to project equally on each side of the hive or cover. If in a windy place a brick or stone will be needed on the

Continued on page 862.

General Correspondence

NOTES, NEGOTIABLE AND OTHERWISE

BY ARTHUR C. MILLER

Put on supers when it suits your convenience, and take them off when the honey is ripe, not before.

The first three lessons for beginners should be, How to Light, How to Load, and How to Use a Smoker. Some veterans will please take notice—and lessons.

I had a little skit on the color blindness in bees. The editor left it lying around loose, and Mr. Lovell picked it up, not knowing that it was loaded. My sympathies are extended to the afflicted.

Some old professors said that action and reaction are equal, and opposite in direction. They may be opposite all right, but not equal. Use your finger to push the bee through a hole and you won't ask me any fool questions.

If you have neglected to feed your bees until now you should use one of the candies. They are safer for cold-weather feeding—a little more trouble to make, but a lot easier to use, and a whole lot better for the bees—in cold weather, mind you, and, again, some other times.

If you really want to improve the bee-keeping conditions around you, to help to eradicate bee diseases, get the beekeepers to subscribe to the bee magazines. If every reader will get just one new reader the uplift in bee culture will be beyond anticipation. And I don't own a red cent's worth of a bee paper at that.

If you do not get what you think your honey is worth, do not blame the buyer, the commission house, nor any one but yourself. Probably you are afraid to ask all it is worth, and a little more, and perhaps you are hard up and need the money. Nothing "bears" the market more than necessity. Poor goods stand next.

Never mind the increase in price of lumber. It is a small matter after all, and you can not afford to go without proper equipment and then make up for it in labor. Your own labor is even more costly than what you hire, and you can easily waste many times the cost of the needed appliances by not having them. P. S.—I do not deal in supplies.

A man quoted to me the old saw that bees won't sting you if you hold your breath, and added that it wouldn't work—told him he didn't hold it long enough. Bees don't sting dead things—not if they are quite

dead, and the color is right. Incidentally, the odor of things thoroughly dead does not cause the bees to assail them. I wonder why. Guess they like that odor.

Lost, strayed, or stolen.—One odor theory. A liberal reward will be paid for its return to E. R. R., Medina, Ohio, and no questions asked. [The odor theory is still on deck. The editor is not ready to abandon it just yet. Any thing that tends to destroy or obliterate colony or queen odor by smoking, for the purpose of introducing, may or may not support the theory. We are waiting for more evidence.—Ed.]

Have you begun your plans for 1915? Yes, I mean that year, for those for 1914 should have been made long ago, and need only a little polishing up. That sounds foolish, like a waste of good space, for the year-ahead planners will do it anyhow, and no power known to man can start the other kind into getting a move on. But there may be some who only forgot, or are taking a nap, so I guess we will let it stand. And, by the way, do not confuse real planning with day dreams. They are quite different.

Funny what different *notions* are held on smokers and the use of them. A good many of the boys use any kind that may be at hand, and a lot of others want something very special. One wants a little vest-pocket affair. Another wants something on the style of a smelting furnace, and about as handy. One will spend much of the daylight hours in stoking, while another seems able to make a pinch of fuel do all day. One will suffocate in a cloud of smoke, and another will forget there is such a thing. And there are some benighted individuals who persist in using a nasty old pipe filled with tobacco. Say, wouldn't it make some show to line up the boys with a collection of the sundry varieties, and set them going?

There is one way to sell your honey which will bring top price, take all you raise, and drive you distracted to meet the growing demand. Produce the rich, ripe, come-again kind. It sells itself as well as rum. And right there lies a tale—a true tale. A certain dealer in bottled liquors ordered a few jars of honey to be used with liquor for coughs and colds. Soon more was wanted; then more and more, and yet more. Each year the volume has increased. Great quantities have gone to people who never use liquor, and now the dealer says that if the trade keeps on growing it will exceed his liquor trade and drive him out of it. The honey has always been of the highest

quality, and sells itself. It has become a staple, a necessity, and the producer thinks it a good way and a good place to fight liquor. When a club fails, try sugar plums.

Providence, R. I.

A VISIT WITH R. F. HOLTERMANN IN CANADA.

A Modern Twelve-frame Power Extracting Plant; Troubles with the Honey-pump Overcome; the Steam Uncapping-knife vs. the Cold Knife; Capping-melters vs. Draining-cans.

BY H. H. ROOT

R. F. Holtermann, of Brantford, Ont., Can. Mr. Holtermann is wintering 700 colonies in Ontario, and 150 in Missouri.

Ever since Mr. R. F. Holtermann bought his twelve-frame extractor I have been promising to cross over into Canada in order to see it work and to see several other things work besides; but circumstances prevented my going until July of this year. Early in July Mr. H. wrote that the honey-pump was not working properly, and that I would simply have to come. I learned later that there had been

some speculation among the students working for Mr. Holtermann as to whether I would dare show up, and that Mr. Glen Holtermann, who, by the way, is six feet tall and then some, had said that they would see when the time came that I would make some excuse and stay at home. However, contrary to expectations, Glen, who was waiting at the station with the auto, saw me get off the train at the appointed time. We started at once for the particular yard that was being extracted, several miles away. I had no need to ask Glen whether they had already begun work for the day, for he was decidedly "stuck up," in spite of the fact that he was dressed in bib overalls.

Although the distance from the station to the yard was between five and six miles, we covered it in a very few minutes in the auto. About a year ago Mr. Holtermann decided he could no longer waste his time in going from yard to yard behind a horse,

and so he purchased a five-passenger automobile—an Overland—which has proven a good investment in more ways than one. Frequently the "democrat," loaded with fixtures, is towed behind the machine. Light loads in a single wagon may be pulled easily over good roads, and much better time made, than with a horse. Of course, the average automobile is not adapted for towing heavy loads.

When we reached the yard I went at once to the honey-house, and a busy scene met my eyes. In all, there were six helpers keeping the twelve-frame extractor going, besides those out in the yard. Fig. 1 shows the whole plant, although this particular view was taken at another yard.

Before describing in detail the various parts of the extracting outfit it may be well to mention that Mr. Holtermann drives his twelve-frame extractor with a gasoline-engine, which, to economize space in the room, is located outside the building, the belt running through a hole cut in the wall, Fig. 2. The pump conveys the honey from the bottom of the extractor to one after another of the large tanks seen in the background of Fig. 1, each of which holds about 3400 pounds. The tanks, of which there are about 26 in all, are six feet high and three feet in diameter. Mr. Holtermann does not use a capping-melter, having, instead, two large uncapping-tanks in which the cappings drain. He is using for the first time this season two steam uncapping-knives. Heretofore he has always used cold knives entirely. After being uncapped the combs are placed diagonally, as shown, in a super which stands over a large square pan to catch the drip.

When I arrived I noticed that the belt was not on the pump. It would not stay on, in fact; and the pump, while a thing of beauty, was hardly a "joy forever." Nearly the whole time of one man was taken in drawing off pails of honey from the bottom of the extractor and lifting them up and pouring the honey into those high tanks. I at once saw that two mistakes had been made in following the instructions, and we proceeded to make them right. In the first place, the large pulley was located on the extractor shaft and the small one on the pump. We exchanged pulleys, putting the small one on the extractor-shaft, and the large one on the pump, thus reducing the speed greatly. It depends somewhat on the temperature of the room, and of the honey also, on the height to which the honey must be elevated; but if the pump runs 60 to 100 revolutions per minute it is fast enough for all requirements. Mr. Holtermann's extractor being a twelve-frame, the pump was

FIG. 1.—Interior of one of R. F. Holtermann's extracting-houses. The young man on the left is Walter Hull, of Connecticut. The next is Warren Munroe, of Ontario. These two were students with Mr. Holtermann this last season. Glen Holtermann is shown at the extractor.

running a trifle over 100 revolutions per minute.

We next took down the $\frac{3}{4}$ -inch pipe which conveyed the honey from the pump to the can, and replaced it with one-inch pipe. When this change was made the pump ran easily with a comparatively loose belt, and kept ahead of the extractor without effort. On one occasion when swinging the horizontal pipe to the next tank we found it was not quite long enough to reach. We threw the pump belt off, therefore, while we were putting on a longer pipe, the extractor being kept running all the while. It took about ten minutes to rig up the longer pipe; and during this time the level of the honey in the extractor-can had risen to a point where it was almost touching the bottom of the reel. In less than fifteen minutes after the belt was put on, the pump had "caught up" and we could see the bottom of the extractor again.

It was with a great deal of interest that I watched the operation of this twelve-frame extractor; for it has been suggested more than once, that, since centrifugal force is greater closer to the center, other conditions being equal, it is possibly a mistake to use extractors that are so large. However, it is perfectly clear in my mind that, since the

velocity of the combs is so very much greater in the larger cans at a given reel speed, this more than offsets the slight disadvantage of having the combs further from the center of the reel. Practical proof of this was not lacking; for this twelve-frame extractor emptied the combs in less time than I thought was possible; that is, it required less time for a set of combs, considering the heavy body of the honey, than any extractor that I have ever had any thing to do with.

In order to keep the extractor moving as much of the time as possible, Mr. Holtermann has two men ready the instant the reel comes to a stop, one to take out the empty combs and the other to put in the full ones to be extracted. I found that the average time required to change the twelve combs was fifteen seconds. Although the honey had just been taken from the hives, so that it was quite warm, it was nevertheless of very good body, and the average time that the combs were whirled was two and a half minutes. This means that in every two minutes and three quarters, or in every three minutes at the most, a twelve-frame super of honey was extracted. Theoretically this would figure, counting five pounds to a comb, something over 1000 pounds per hour. Taking into considera-

tion occasional delays, the average rate while I was there was about 700 pounds an hour.*

Mr. Holtermann himself works in the yard, having two helpers to assist him. Fig. 3 shows the process of removing the honey from the hives. One helper is provided with a smoker, and the other with two brushes. The one with the smoker removes the cover, loosens the frames, and handles the smoker, while Mr. Holtermann shakes the frames one by one, then holds them momentarily while the second helper brushes them clean of the few bees remaining, both sides being brushed at one stroke. On several different occasions the three men removed from the hives, cleared off bees, and brought to the honey-house, eight twelve-frame supers in ten minutes. This, however, is a trifle less than the *average* time taken.

At some of the yards a small push cart on a wooden track is used, Fig. 4. Mr. Holtermann is greatly pleased with this arrangement, and expects to install a similar cart and track at each yard. At some of the yards the "democrat" is used for convey-

* I have learned since writing the above that Mr. Holtermann's entire crop this past season ran something over 80,000 pounds. One apiary averaged over 160 pounds to the colony; another, 150 pounds, etc. He fed sugar this fall at the rate of 5 pounds per colony.

FIG. 2.—Gasoline-engine located outside the building, and belted to the extractor through a hole cut in the wall.

ing the honey up to the extracting-house. Fig. 5 shows the vehicle in question with empty supers ready to go back to the hive. Each extractor-house has an opening in the side through which the full and empty supers are passed to do away with the loss of time and greater danger of robbers caused

by opening and shutting the regular door.

THE UNCAPPING - CAN VS. THE CAPPING- MELTER.

Mr. Holtermann has never used a capping-melter, but has seen it in use enough to make up his mind that he does not want such an outfit for his own use. He figures that the capping-melter, while it melts the wax and separates all of the honey, requires much more attention than an uncapping-can, which time could be used to better advantage at something else during the height of the extracting. Furthermore, while the flavor of the honey need not be injured if the melter is properly constructed, yet the color is apt to be darkened slightly.

The uncapping-cans are shown in Fig. 1.

FIG. 3.—Mr. Holtermann and two helpers removing honey from the hives. One helper opens the hives and manipulates the smoker. Mr. H. shakes the combs, then holds them while the second helper with two brushes clears off the few remaining bees.

FIG. 4.—The supers of honey loaded on the car, ready to be pushed to the extracting-house. Mr. Holtermann is greatly pleased with the car and its wooden track, and he expects to install a similar one at each yard.

A perforated-metal basket, only slightly smaller than the can itself, but just two-thirds its depth, occupies the upper half of the can. There are two cans, one for each operator, and they hold enough for half a day's work. The cappings are frequently punched and stirred with a board so that they are comparatively dry when taken out and transferred to a barrel. Two barrels will hold drained cappings for the entire extracting at each yard. The honey in the bottom of the uncapping-can is run out into pails and lifted up into the main tank. Mr. Wm. Lossing, of Phoenix, Ariz., uses very much the same plan but goes a step further in that he has a hose leading from the bottom of the uncapping-can to the bottom of the extractor, so that the pump elevates the honey from both into the tank.

THE STEAM UNCAPPING-KNIFE.

As mentioned before, Mr. Holtermann has not used the steam knives until this year; in fact, he told me he had been rather opposed to them, but he finds them a great improvement over the cold knife. With the steam knife Miss Holtermann was able to uncap three combs per minute, and keep up this rate right along. At this speed I fail to see why any one should need an uncapping machine. There is not a machine that has ever been tried that will uncap all combs. There is a certain amount of hand work that must be done any way. Taking this into consideration, it is my opinion

that no machine will ever be built that will exceed the rate of three combs per minute. I know that, under the most favorable circumstances, when the combs are uniform and bulged, a greater speed than this has been made with a machine. I know, too, that the advocates of the uncapping-machine have suggested that the honey-producers must take more pains to have their combs uniformly bulged on both sides. However, when all is said and done, it is my honest conviction that the uncapping-machine will be no nearer perfection ten years hence. In saying this I am not trying to throw cold water on the efforts of any one. I merely believe, as I said before, that no uncapping-machine, *taking into consideration the best combs that the average producer will have*, will ever exceed the simple steam knife.

It takes three operators with cold knives to keep up with the twelve-frame extractor, and only two using the steam knife. Mr. Holtermann was having a little trouble because the water in the boiler evaporated so fast that frequent additions were necessary. I think his trouble was that the oil-stove used could not be properly regulated, and there was far more heat than was really necessary. With a stove that can be turned no higher than required, two quarts of water will run the knife half a day, so that the boiler needs filling only once in the morning and once at noon.

Fig. 6 shows a corner of one of Mr. Holtermann's yards. The hives are located in groups of four. In the fall, after the supers have been removed, the four brood-chambers are located in the winter case that Mr. Holtermann has described in these columns before. Fig. 7 shows the cases set at one side of the yard, ready for use again this fall. By this plan the labor of packing and getting ready for winter is reduced to a minimum, and the colonies winter perfectly. It will be remembered that Mr. Holtermann, formerly one of the strongest advocates of cellar wintering, now winters entirely on the summer stands by the use of these mammoth winter cases, each of which holds four twelve-frame colonies. A full description of these cases, how they are made, etc., is given on pages 693-696, Nov. 15, 1911.

Fig. 7 also shows a new-style cover. Mr. Holtermann likes these better than any other he has ever used, and he has had a pretty wide experience. The cover proper is merely a square pan, inside of which is loosely placed a rim or frame made of $\frac{7}{8}$ material. Fig. 8. Inside this rim are placed several layers of heavy strawboard. The layers of strawboard furnish an excellent protection from the hot sun, and also make a very warm cover in spring and autumn. The galvanized-metal roof, the corners of which are soldered, makes the whole thing waterproof. Of course, when the cover is removed ordinarily, the inside part is lifted off with the metal part—that

FIG. 5.—The "Democrat" used to carry supers to and from the extracting-house at the yards where there is no cart and track.

is, the whole thing comes off together. In the picture Mr. Holtermann has merely lifted up the metal part to show the construction underneath. A quilt is laid over the top-bars before the cover is put on.

Just as I was leaving I secured a picture of Mr. Holtermann, his son and daughter,

FIG. 6.—A group of four twelve-frame hives, three of which had four supers apiece. In the fall the four hives are moved a little closer together, and the winter-case shown in the next illustration is set down over all.

FIG. 7.—The large winter-cases piled at one side of the apiary, ready for use in the fall.

and his four helpers, the latter stopping for a moment just as they were starting for an outyard. Fig. 9. Mr. Holtermann may well be proud of his efficient helpers, and they in turn appreciate the experience they are getting in so short a time. For my part, I never enjoyed two days' work more than the two days last July when I, too, was a Canadian.

Continued in next issue.

THE STEAM-HEATED HONEY-KNIFE AND THE HONEY-PUMP

BY R. F. HOLTERMANN

Beekeepers should be more interested in hearing of something which will reduce the expense and trouble of the production of honey than in reading about great honey crops. That which reduces the cost of uncapping before extracting, reduces the cost of producing extracted honey. Especially during the time of extracting labor is scarce and high-priced in this locality. This applies particularly to skilled help for the beekeeper. Doubtless this is true in many other localities. Give me any thing which cuts down the help required in extracting, and I shall be enabled to "keep more bees."

When, some years ago, Mr. E. R. Root handed me a steam-heated honey-knife, telling me that I could try it and he would like to have my report, I thought to myself, "I can not be bothered with a knife having a rubber tube at one end to hamper and restrict the uncapper's movements." I thought, too, that the extracting-house was hot enough without artificial heat. Consequently the knife was put upon the shelf. Some

time after, I mentioned the matter to F. J. Miller, of London. It was late in the season, and he had some extracting to do. He asked me to send it to him, saying that he would try it. This made me feel that what was of no use to me should not be of much use to Mr. Miller; and, of course, what would or could be of use to Mr. Miller might be of use to me. However, the steam-heated honey-knife was not tried the following season.

By last spring, however, inasmuch as

there was much greater capacity for extracting I began to feel the need of something to assist in uncapping. I have had splendid help in uncapping; yet there was an apparent need of more help in this direction, so I ordered an outfit of steam-heated knives and one boiler having two outlets, to which to attach the rubber tubes

FIG. 8.—Details of the metal cover. The metal part is made like a large square pan with the corners soldered. The inside part, which is removable, consists of a rim filled with several thicknesses of heavy strawboard.

FIG. 9.—Mr. Holtermann and his force of helpers. Reading from left to right: Warren Munroe, Closson Scott, Glenelg Holtermann, Louise Holtermann, R. F. Holtermann, W. White, Walter Hull.

and knives. They came, we saw, they conquered. One uncapper can readily do in one hour what it required $1\frac{1}{2}$ hours to do before, and then leave the comb in better shape. More, for it tends to warm the honey in the comb, so that it extracts more readily. The honey also, being warm, separates from the cappings more easily. Again, where the honey has been taken off the hive and away from the bees some time previous to extracting, the honey is somewhat rewarmed.

For new combs or, rather, combs which are not strengthened by cocoons left by hatching bees, the steam-heated knife is best of all, and overcomes with the greatest ease difficulties of a real nature. Where the combs have been used in the brood-chamber the steam-heated knife can not melt the cocoons; but if the knife is kept sharp they can be cut as before by the unheated knife. We do not expect to use the cold knife in the future.

THE HONEY-PUMP.

With the intention of trying to reduce labor in extracting, I conceived the idea of pumping the honey from the extractor to the tank. The pump I had formerly tried did not work; and during the season of 1912 we ran all our honey from the extractor into a pail and dumped it into tanks six feet high. With one twelve-frame extractor this kept one man fairly busy; but since a proper pump has been attached to the ex-

tractor, and in a proper way, the pump does this work without any danger of running over on the floor or dripping, and this almost saves the labor of one man. These two changes have proved a great help to me in extracting.

We hope to have next season two twelve-frame machines run by one engine side by side, and expect to have our combs thoroughly dry when leaving the extractor, and at the same time be able to extract readily 1200 lbs. per hour.

Brantford, Canada.

REQUEENING WITHOUT DEQUEENING

Some Interesting Facts

BY ARTHUR C. MILLER

"Eyes have they, but they see not; they have ears, but they hear not."

In GLEANINGS for Nov. 1, 1913, page 747, near the top of the second column, appears the following: "'Why, the other day,' said our Mr. Marchant, 'by error I introduced by the smoke method a queen in a hive where there was already a nice laying queen. Would you believe it? they accepted the introduced queen and killed their nice layer! What do you think about that?'"

Evidently both Mr. Marchant and the editor did not think along the leading line. Right before their eyes lay bare one of the

most promising innovations in bee culture. It is this: *Requeening without dequeening*. I have been doing it for some time in an experimental way, trying to find the basic laws, for as yet I can not succeed every time. I am not sure as to what conditions are essential to uniform success, and hence have hesitated to say much about it. But the present seems to be an excellent time to broach the subject. The eye of the bee-keeping world is on the new method of introducing, and all its variations and possibilities will be discussed and tried out, hence I believe it wise to mention what I have so far done, even though the work is not complete.

In the past I have stated that it was possible to introduce a plurality of queens and have them all accepted, but sooner or later all but one disappear. Keeping a plurality of queens in a colony has long been a dream of many, as a way to have large colonies. Its practicability or wisdom is not now under consideration, but the subject is cited merely to recall what has been attempted, and show how very near to a new thing some of the experimenters came.

Permanent plurality of queens had proved impossible; but the fact that bees would even for a time tolerate a plurality of queens (not under supersedure conditions) suggested to me the possibility that perhaps a young queen might be given without removing the old one and have the former supersede the latter. It was easy to put in the new queen, but it was not always the new one that survived.

Why? Frankly, I do not know. But if it works properly in a few cases it will be possible to make it work at our pleasure when we learn the laws underlying their behavior.

At present my idea is this (and please note that I am only stating it as a working hypothesis, that others may take up the work with me): A young queen light in eggs easily overpowers an older queen heavy with eggs. Also, such a young queen usually conquers an old and failing queen. If such proves to be always true, we have only to introduce an active queen light in eggs to a colony when its queen is heavy with eggs to have the desired supersedure take place.

Now, note this: A queen once safely in is safe until she meets the other queen. The more nimble queen usually wins; but sometimes, when perhaps queens are about equally matched, the bees take a hand, and then results are impossible of forecast, and either queen may be the victim.

The problem then is to ascertain the best age and condition of the new queen, and the

most favorable conditions in the receiving colony. Perhaps some day we may find *requeening without dequeening* simple at any time; but just now the conditions above set forth seem necessary, and even then the results are not uniform.

Providence, R. I., Nov. 10.

[Our correspondent may be on the right track. We believe he is correct when he says that "a queen light in eggs easily overpowers an older queen heavy with eggs." We have noticed this time and time again. In the same way, an interloping virgin—that is, one going into a hive by mistake, where there is already a laying queen—will in most cases supplant the reigning mother, for the very reason that Mr. Miller states.

We believe, also, he is right in saying that "a queen once safely in is safe until she meets the other queen." We have seen not a little corroborative evidence of this—so much so that we have come to believe that, when there are two queens in a hive, the bees rarely take a hand in the fracas between the rivals. They allow the rule of the survival of the fittest to work out, for "to the victor belong the spoils." It is a well-known fact in apiculture that two colonies may be united, each having a queen, without paying any attention to either queen unless there is a choice; but a further examination will show only one queen in the hive. It is probable that the rivals "settle their differences" by one killing the other. A royal combat between queens does not end like a duel between two men, both being injured or possibly killed, but in the case of queen bees it is simply a case of death to one without injury to the other.

We are glad that Mr. Miller has presented the case, even though he is not at present sure of his premises.

The following article touches on a phase similar to the one just preceding.—Ed.]

REQUEENING WITHOUT KILLING THE OLD QUEEN

Two Queens in the Hive for the Fall Work

BY J. B. MERWIN

The requeening of our hives without killing the old queen is a method we have practiced in our yards for some time, and find it superior in a good many ways to the old style of requeening. In taking off our supers or upper stories for the last time early in the fall or late summer we often find a few hives, which, for various reasons, we wish to requeen. The queens in these hives may be old ones, others may not be doing good work, and some we wish to requeen for bet-

ter blood, etc. Now, as the honey-flow draws to a close, and while there is still some honey coming in from fall flowers, we go to these hives that we wish to requeen and cage the queen of each hive. We make a note of this, and on the third day from the day we cage the queen we go to the hive from which we wish to requeen and take out a small piece of comb containing larvæ of the desired age. With this wrapped in a piece of cloth we go to the hive containing a caged queen. On opening this hive we find already started several queen-cells, each containing a larva and plenty of royal jelly. We now destroy all queen-cells excepting two or three nice ones, or as many as may be desired to leave, and with the transferring-instrument pick out the larva from these and transfer the larva from the piece of comb from the breeding queen. We next put back the frames, liberate the old queen, close up the hive, and when opened again in a few weeks one will be surprised to find two queens laying, sometimes on different combs, and again you will find them both on the same side of one frame.

This plan will work well on all queens two years old or over. We have not as yet tried superseding yearling queens by this plan. The old queen will not tear down the cells as supposed. Queens reared by this method are the same as queens reared by natural superseding (at least they never fight, and I never heard them quarreling).

You will find this method superior to the old in more ways than one. Your hives are in no danger of becoming queenless, or the bees balling the queen when introduced. The queens are seldom lost in mating. Nine times out of ten you will find the two queens in the hive when you open it.

I presume that a queen-cell with a larva several days old could be introduced in place of transferring the larva, but we never gave this a trial.

At the present time, Sept. 8, we have several hives with two queens, and we expect to requeen a few more yet this fall, as we have a late fall flow of honey here from wild thyme.

To make the above plan a success you must be sure to destroy all queen-cells and cups excepting those you have transferred the larva to. With strong colonies we shake the bees from the frames. This gives one a chance to find all the cells.

Prattsville, N. Y.

[We believe Mr. Merwin has struck on an excellent plan for superseding old queens. It might work in the case of a yearling, but we doubt it. This will be worth pasting in the hat and trying out after the harvest next year.—ED.]

SKETCHES OF COLORADO BEEMEN

BY WESLEY FOSTER

HARRY CRAWFORD

I think it was in 1898 that father took a one-horse wagonload of comb honey to the city of Denver. I was allowed to go along to see the wonders of the great city. About half way between our home and Denver is a little station called Broomfield. There was there at that time a postoffice and store combined, a creamery, and a railroad station. Two or three houses made up the remainder of the village. A low white cottage set among a small clump of trees disclosed to our view a neat little apiary at the rear of the grounds. Close beside the house, but abutting upon the street, was the postoffice and store of the village. As father always enjoyed the association of beemen we decided to stop and water our horse and get some crackers and cheese for our lunch.

We met a quiet, unassuming young man, slight of build, about average height, and perhaps thirty years of age. This proved to be our first acquaintance with Harry Crawford, who was running the store and postoffice and caring for bees on the side. His apiary consisted of perhaps fifty colonies in neatly painted dovetailed eight-frame hives. Order seemed to be in evidence everywhere, and an absence of hurry and rush was another factor noticed. Mr. Crawford had not been married very long, and told us he was increasing his bee operations as rapidly as possible. In a short time he hoped to drop the store and postoffice business and use the room for a honey-house and shop. At that time he had one or two hundred colonies rented from others that he was operating on shares in outyards. In this way, by getting half the swarms he was steadily increasing his own numbers. His health had not been good for a number of years, and soon after our first meeting he began taking his family to California for the winter, where living is so delightful, and his health improved greatly.

Comb honey is Mr. Crawford's sole production, and the economy and systematic management of his work makes it possible for him, although not a robust man at all, to care for five hundred to seven hundred colonies with a small amount of help. Mrs. Crawford, of course, helps, and, I believe, some winters she has put together most of the sections. Miles, their oldest son, who is about twelve, is a great help to his father in the apiaries.

Mr. Crawford has all supers, about $3\frac{1}{2}$ to each hive, filled and ready during the winter. All hives for increase are nailed and painted in readiness. During March

The birthplace of the Langstroth hive at Lyonsville, Massachusetts.

the apiaries are each year gone over, and any colonies found in a weak condition are placed on top of the strong colonies. No further attention is given to the bees till May, when heavy breeding begins. Stores are then equalized, if necessary; but little fussing is done with the bees to encourage quick breeding.

Clipping queens' wings is not practiced. Mr. Crawford inspects bees for swarming tendencies by lifting the hives up from the bottom-boards and looking for cells. By cutting cells and giving adequate surplus room and ventilation, swarming rarely causes any trouble. Colonies that persist in swarming are divided.

Foul brood is not tampered with. Hive, comb, honey, bees, and all are burned in a deep hole, and the ashes covered. Mr. Crawford has had very little foul brood to contend with.

All of Mr. Crawford's dealings are performed with deliberation. He bought an eighty-acre farm at \$50 an acre, and the bees paid for it in a few years. About a year ago he sold the farm for \$125 an acre. This has helped him to get well established where an occasional honey-crop failure will not seriously affect him.

Mr. Crawford has been a stockholder and director in the Colorado Honey-producers' Association from the first. He has the second Rauchfuss combined section-press and foundation-fastener that the Rauchfuss brothers made, and has used the machine every year. Several hundred thousand sec-

tions have been put together and started with it.

I have been told that, during the rush of the summer's bee work, when most beekeepers are working early and late, Mr. Crawford will lay off a day every little while and take his whole family to see a show. He told me that this year, when he harvested nearly a carload of comb honey his apiary work would be finished early on Saturday of nearly every week, and he would have the larger part of the day for rest.

Other beekeepers have made more money some years, but I doubt if any one in the Rocky Mountain region has averaged more year after year, and accomplished it with less stress and worry, than has Harry Crawford.

Boulder, Col.

THE BIRTHPLACE OF THE LANGSTROTH HIVE

W. W. Cary and L. L. Langstroth; Apiary and Business of Earl M. Nichols

BY E. R. ROOT

When bee culture in the United States was in its early stages in the late 40's, there was a galaxy of brilliant men who were interested in bees. First and foremost we should, without question, name L. L. Langstroth; then Moses Quinby, Samuel Wagner, Richard Colvin, Adam Grimm, Roswell C. Otis, and last, but by no means least, W. W. Cary, of Colerain, Mass. Up in the hills of Massachusetts, in Franklin Co., Mr.

A part of the vinegar-plant and home of W. W. Cary & Son, Lyonsville, Mass.

Cary began keeping bees. By a very fortunate combination of circumstances Mr. Langstroth, then principal of a ladies' academy at Greenfield, Mass., got in touch with Mr. Cary at Colerain. Langstroth was developing his hive, and needed a practical man like Cary to test it. While in West Philadelphia Langstroth had been studying Huber, and he had learned much from that wonderful naturalist, who, although he had no eyes, saw far more of the mysteries of the hive than any who had preceded him. Although he felt much indebted to this prince of investigators, he saw that the Huber leaf hive was too crude to yield practical results. But crude as the hive was, Huber was able to separate fact from fiction. These he later gave out in a series of remarkable letters to his friend Charles Bonnet. This series, for accuracy of observation and a general fund of information regarding the habits of bees, has never been surpassed. Indeed, it may be said that Huber furnished the fundamentals of modern scientific bee culture; but it remained for Langstroth to develop a hive and system that would place beekeeping on a practical and commercial basis. How natural, then, that he should seek out a man like Cary! It seems that various models of his hive were made in the Cary workshop. These hives were then placed in Mr. Cary's apiary to be tested out.

If we could do the paradoxical thing of reading between the lines of unwritten history, we should probably find that W. W. Cary was the mechanic who furnished Mr. Langstroth not only skill but a shop in which to perfect that wonderful hive that

made it possible to remove any one comb without interfering with any of the others, and without the necessity of slicing any comb from the inside of the hive itself.

At all events, it was after Langstroth left the Cary workshop that he patented his hive and his book. This was published in 1853, a reprint of which will soon be ready for the public. How much of value Mr. Cary himself contributed to the success of the invention we do not know and never shall. When we visited Earl M. Nichols, a son-in-law of H. F. Cary, this very workshop was still in existence, and at the time of our visit it was standing without alteration as in the days when Langstroth graced it with his presence. Unfortunately we had only a small kodak with us. Eagerly we pressed the button, and here it is. The building, we understand, has since been removed to make room for a building of greater capacity for the growing business of W. W. Cary & Son and the son-in-law, Earl M. Nichols.

As has been done many times before, Herbert F., the son of W. W. Cary, took up the work of his father and built up a magnificent business in the manufacture of pure cider vinegar, for it seems the senior Cary produced honey and vinegar; and while the junior Cary continued both lines of business he appears to have transferred the beehive to his son-in-law, Mr. Nichols. In the mean time Mr. Cary devoted all his time to the vinegar business until he had a plant that is one of the largest and best in the United States. There may be larger vinegar-factories, but probably none whose production is confined entirely to a product from the juice of the apple.

The side hills all about Lyonsville (a short distance from Colerain) are peculiarly favorable for growing apples, and they are frequently found growing there in their wild state. The modern apple-grower knows he must have, in order to get the best results, what he calls "air drainage" as well as water drainage. These hills are well adapted to both, and hence we find immense quantities of apples are produced naturally and in a cultivated state all over this part of the country. Indeed, this vinegar-plant has developed a demand for apples, so that more and more are being produced.

We found a beautiful home on the side hill, the factory buildings in convenient reach, and a new up-to-date private water-works plant drawing water from a lakelet higher up on the hill. Mr. Nichols, the bee-man, is certainly a live wire. He is engaged, not only in the production of honey, but in the sale of beekeepers' supplies, and during the off season helps out in the vinegar business. It is but natural that he should continue the supply business, because the senior Cary was an expert maker of foundation and a queen-breeder. Langstroth said of him, in a glowing tribute which he paid to his friend in *GLEANINGS* for 1886, page 11, that he was the first man to send a queen across the ocean in a single-comb nucleus with a few workers. No small wonder that he should find that he was the man to help him perfect his hive.

The apiary of E. M. Nichols, with Mr. Nichols in the foreground, is shown on the front cover page of this issue. The first real Langstroth hive that was ever made was placed in this apiary in the very spot where Mr. Nichols is sitting. This apiary certainly enjoys a distinction that no other apiary has or can have. The more distant view shows the home poultry-house and the beeyard over to the extreme right. The whole plant in all its details shows the result of splendid business management. The presiding genius of the whole, Mr. Herbert F. Cary, seems to have the faculty of casting his mantle on his sons and son-in-law. At any rate, they have the business so well organized that they turn him out to grass, as he says—that is to say, he and his wife go to Florida every winter.

NEW FOUL-BROOD LEGISLATION PROPOSED

BY H. E. HARRINGTON

On page 138, March 1, the editor of *GLEANINGS* tells of a tramp beekeeper spreading bee disease, and speaks of making laws to control the situation. Well, there are many beekeepers who are not

tramps, but farmers, who are doing just as bad if not worse work than this tramp, because their name is legion. They do not pretend to know much about bees, but just keep a few for honey for their table. Their colonies may be reducing each year, but they seem to find a way to account for it, and declare they have no foul brood. They seem to think that if bees have foul brood they will find something in their hives as big as a fire-log.

The inspector is generally handicapped for funds to pay for the work. With all the laws we have, bee disease has increased throughout the United States as a whole.

While in Washington and Oregon I became convinced that a compulsory law would have to be made before the bee-disease situation could be controlled, just the same as those States made compulsory spraying laws, by virtue of which a person must spray his fruit-trees, or cause them to be sprayed, or they would be cut down. This law controlled the situation; and the result was perfect fruit that brought high prices.

I will propose a new law, that a person to keep bees lawfully must have a legal permit to do so. The State Beekeepers' Association should have rules compiled or sanctioned by the Bureau of Entomology, Washington, D. C., saying just what treatment a healthy colony of bees should receive in a diseased locality—viz., inspection. The said association might propose certain persons appointed in certain places as most convenient to grant permits, and the governor of the State would appoint them. These rules should be so compiled that the applicant, on signing them, agrees to them, thus making a contract with the State or county. Literature telling how to detect and recognize said disease or diseases, and the treatment for the same, with a lawful permit to keep bees would be given to the applicant, and a small fee charged. If the applicant wants assistance the office could furnish it; but the applicant should pay a fair sum for the work.

The office should see that he keeps his contract, and if any old neglected cases of disease were found among his bees he should be fined for each case so found. This would go to the office.

If a person refused to obtain a lawful permit the State could prosecute him and fine him, both spring and fall, for all colonies so kept.

These, in brief, are the main points of the law I would propose made. Of course, changes could be made in it as might seem necessary. The old laws would then be canceled. A small appropriation should be

made by the State. It seems to me that this will control the bee-disease situation perfectly; and as it would be a matter of record, statistics could be quickly and accurately made.

Lyndon, Vt.

MAKING THE MOST OF INSPECTION

Better to Spend Funds for Education

BY FRANK C. PELLET

In States where beekeepers have not already secured the desired legislation it is very important that they start right and thus save the annoyance of having to make a second fight to secure better laws. Each State seems to have different laws, and every inspector seems to have a different plan. It is almost impossible to secure a sufficiently large appropriation to do thorough inspection work over the entire territory where disease is present in any State. That being the case, educational work is even more important than the actual inspection. After two years' experience as State Inspector I am fully convinced that it would not be wise for the State to expend the necessary amount to inspect all diseased colonies, even though a legislature could be induced to provide the funds. In my opinion it is better to provide an amount sufficient to meet all emergencies, and to expend the greater energy in educational work.

In this State the inspection work is in charge of an official who is designated "State Inspector of Bees," with power to appoint deputies. The term of office is two years, and the inspector is appointed by the Governor. It thus becomes a political appointment. Fortunately, so far no friction has developed between the Inspector's Department and the beekeepers. The beemen have been uniformly friendly, and have rendered every possible assistance in finding disease, either in their own apiaries or those of the box-hive farmers who permit a few colonies to remain in some out-of-the-way corner. Iowa is also fortunate in having a governor who is not inclined to ask any questions about a man's political affiliations when making appointments of this kind. There is danger, however, in making an office of this kind a political appointment; for in many cases the office is filled rather because of political connection than personal efficiency.

Last year I became convinced that our present plan was not the best, and accordingly recommended that the work be placed in charge of the State Entomologist. A bill was accordingly introduced in the lower

house with that end in view, and I was called before the committee in support of it. The thing looked so reasonable to me that I expected it to pass, and prepared to turn the work over to Prof. Summers, and expected to be relieved of further responsibility in connection with the inspection. The bill, however, was defeated in committee by one vote, and I still hold the job. There was some fear expressed that, should this work be added to the Entomologist's other duties, it might suffer because of being placed in the hands of incompetent men. Those who know Prof. Summers and his thorough manner of dealing with every thing placed in his charge had no fear on that score.

If I were planning a campaign from the beginning in a State where no laws had already been passed I would begin by working for the establishment of a school of beekeeping in connection with the State Agricultural College and the inspection work in connection with the school. It is difficult to get high-grade men for a few weeks in the spring and summer for the amount available. If the same men can be employed during the fall and winter months in the college it will be possible to get the best talent in charge of our bee work, and to keep them employed throughout the year. Too much importance can not be placed on the work of the college in class work, bulletins, and extension lectures in the farmers' institutes.

In States where nothing is being done for apiculture at the agricultural college, nothing is to be gained by placing the inspection of bees in charge of the entomologist, as at best it will be a matter of secondary consideration with him.

Here in Iowa we are working for the establishment of a department of apiculture at the Agricultural College, with the idea that the inspection work will ultimately be combined with educational work in charge of this department, all of which will naturally fall under the supervision of the Entomologist.

Atlantic, Iowa.

CONDITIONS UNDER WHICH SWARMS MAY CARRY FOUL BROOD

BY GLENWOOD BEARD

With reference to footnote on p. 734, Oct. 15, in answer to J. E. Battram, of Ontario, Canada, I would say that swarms from colonies infected with American foul brood *do* carry with them honey which is diseased, and a number of times I have seen the dead larvæ in newly built combs drawn from full sheets of foundation.

This question, in my experience, depends wholly upon the time of year and season. In a season giving a good honey-flow and during or immediately after such a flow, a swarm seldom carries disease with it sufficient to show when hived in full foundation sheets, while in a moderate or slow honey-flow, where colonies are badly infected with disease, I have known swarms to carry disease which would show in the first set of larvæ in new combs drawn from full sheets of foundation. A colony showing but a few infected cells where disease is just beginning to develop is not to be considered in comparison with a colony in the advanced stage.

A swarm from the one showing but a few cells can safely be given full sheets of foundation unless it is previous to or long after the main honey-flow.

I had ten years' experience in keeping my apiary at home free from American foul brood. A number of my neighbors had a few colonies of bees, and we all knew that the malady was lingering about, but no one seemed at all alarmed about it. I had a hard fight in making some experiments. I was defeated, as disease was so general I didn't know whether my plans had been given a fair trial.

An apparently healthy swarm hived on one-inch starters, a swarm which has built a set of combs completely, and has honey and healthy larvæ, may become diseased at this point, because a swarm from a diseased colony united with the bees in question, the trouble showing up in about two days.

I do not think the Quinby treatment and shaking of a diseased colony upon full sheets of foundation can be favorably compared. A swarm under normal circumstances can stretch foundation in full sheets, with the addition of wax produced by the bees themselves in 24 hours. They deposit some honey, but that length of time is not sufficient for them to consume all the honey they carried.

The Quinby treatment is to build from the start, using only the wax produced by the bees, resulting in the greater production of wax, and more time taken to stretch cells sufficiently to deposit honey.

Barberton, Ohio.

AMERICAN FOUL BROOD

BY A. C. GILBERT

After keeping bees over 35 years the first case of foul brood I ever had or had seen was in the summer of 1910. I had read descriptions and had seen illustrations, and realized, as soon as I looked at a comb, that

it was a typical case. The combs were completely filled with dead and filthy brood, and a very offensive odor was soon detected. After trying the test of seeing if the dead brood was stringy I knew for a certainty it was the American variety.

I decided to find out how it found its way into the apiary. Besides the colony so badly affected I found seven others with a few cells in some of the combs. I then knew that the one colony so much worse than the others must have been affected the year previous. It was a colony with an Italian queen I had bought. That was where the trouble began. I introduced the queen in the cage it was sent in. At the present time there would not be any risk to run, since the candy the cages are supplied with is supposed to be free from all germs. The safest way, however, would be to introduce in a new cage. I said to myself, "I have a job on hand to keep it from spreading."

My first move was to contract all entrances to hives that were affected. I shook the bees of the badly diseased colony off the infected combs on combs of solid honey (except one or two empty combs). Any old combs not perfect, that are free from disease, will answer to catch the honey the bees may deposit for the first day. Then remove and melt up.

The other seven colonies I treated the following spring during a fine flow from the willow, dandelion, etc. The bees were shaken, or, if the nectar was thin, brushed on frames of foundation and one or two empty combs to be disposed of as aforesaid. If they lacked honey before berries and clover yielded they were either fed syrup or supplied with combs of honey. That was the last seen of foul brood in our apiary, and now it is completely wiped out. I think the sooner the disease is discovered in an apiary the better, for it is so much easier to get under control before it spreads.

If inspectors would look after the careless beekeepers (those not up to date, and who never think of looking into a brood-chamber), I think it would soon be annihilated. To sum up, if colonies are weak and badly diseased, destroy them before taking any chances of their being robbed. Leave no honey around to start robbing. Keep entrances contracted, which will often prevent robbing. If a colony is found affected, look over every one in the apiary to know for a certainty whether it is affected or not.

Honeoye Falls, N. Y.

[Instead of shaking on old combs we believe it is far safer to shake on to starters, so that in building comb the diseased honey may be used up.—Ed.]

FEEDING SUGAR SYRUP

BY J. E. HAND

One often hears it said that a pound of sugar syrup, well ripened, and stored within the combs, is the equal of a pound of good honey as food for bees. While I am not in sympathy with the assertion, yet, taken in the abstract, it may, perhaps, be near the truth. Considering the interim, however, the statement is misleading in the extreme. Indeed, if the life-history of the bees, and its relation to the evaporation and inversion of thin syrup were better understood, there would be less talk about the value of sugar syrup as food for bees. Not so very long ago many were advocating sugar syrup as a cheap and effective substitute for honey as food for bees. Some even went so far as to exploit methods and systems to compel the bees to store their honey in the sections in order to enable them to realize a handsome profit by substituting sugar syrup as winter food at half the price of honey.

The delusion was far-reaching and wide-spreading, but it finally became evident to a few that the profits were coming out of the small end of the horn, and it became painfully evident, from the lost vitality and premature death of the bees that inverted the syrup, that its effectiveness did not extend along the lines that harmonize with the financial interests of the beekeeper or the welfare of his bees. I was forced to this conclusion as a result of an extensive experiment conducted with the view of ascertaining results along other lines; but it was equally effective in enabling me to ascertain the effects upon bees resulting from long-continued feeding of thin sweetened water, comprising a solution of 8 to 10 parts of water to one of sugar.

This feed was given in the open, and the feeders were refilled daily from the middle of July to the middle of September, and required the use of a considerable quantity of sugar. The bees took the feed readily, and without any excitement or quarreling, and whenever the feeders became empty they would quietly go about their own business, and there were no robbers nosing about. Indeed, so far as external conditions were concerned, the process seemed to have about the same effect upon the bees as a natural harvest; for I could handle them without smoke, and leave the hives open, and combs of honey exposed, without any attempt on their part at robbing, notwithstanding there was a dearth of nectar during the entire period. The external conditions were so highly satisfactory that I

became quite enthusiastic concerning the artificial honey-flow.

Since this was the main point concerning which I was seeking information, I contented myself with external observation only. Finally, however, I made an examination of the conditions within the hives, expecting, according to theory, to find every thing booming, with plenty of brood and bees; in short, I expected to find conditions about the same as during a continuous mild flow of nectar from natural sources. My expectations were not realized, for the examination revealed conditions of a far different nature than I had hoped for and expected; for while the combs were well filled with seemingly well-ripened stores, evidently the ripening process had a deleterious effect upon the bees, to the extent that in each, and every case the colonies were greatly depleted in numbers, and unmistakably betokened weakened vitality and premature decay of vital tissue. The condition of the brood compared favorably with that of the bees, and was away below normal, as represented where no feeding was practiced.

Notwithstanding these colonies were placed in winter quarters exactly the same as I have practiced for a quarter of a century, with practically no loss, more than half of them were dead before the first of February, and the remainder died before spring. There was no indication of dysentery nor distended abdomens nor fermentation of the stores, and the bees were an exceedingly hardy strain of straight three-band Italians. They were perfectly healthy at the beginning of the experiment. The feed was composed of the best grade of fine granulated sugar obtainable, mixed with pure water in the ratio of eight or ten parts water to one part of sugar. Not being qualified to form scientifically correct deductions based on the results of chemical analysis, I could only reason from analogy, based on the results of external observation and comparison in a general way.

Reasoning thus, all the evidence visible pointed to a loss of vitality and premature death resulting from long-continued and incessant labor of a very exhausting nature in expelling the excess of water from the feed, which can be performed only when bees are on the wing. Hence two months' feeding of so weak a solution would necessitate a flight of hundreds of miles during the season when bee nature demands relaxation from excessive activity, which undoubtedly accounted in a great measure for the general lassitude and worn-out condition of the bees. This theory is supported by the fact that the life-span of bees hatched too late in the season to assist in honey

production is incomparably broader than where the conditions are reversed. While this theory concerning the method of expelling the excess of water may be regarded by some as unorthodox, it can be verified by external observation, and, undoubtedly, by a correct knowledge of bee anatomy.

I was also led to this conclusion by the result of subsequent experiments, where the density of the feed was increased to a ratio of $2\frac{1}{2}$ parts of sugar to one of boiling water. Several colonies were included in these experiments, and on several occasions, with similar results. The fact that this feeding was done for another purpose did not change the results. In this case feeding was continued during the same period, and the bees were given all they would take from a feeder under the hives. An examination of the internal conditions within these hives at the close of operations showed a marked difference in conditions. Some colonies evidently had extra-prolific queens. These seemed to be in a perfectly normal condition with plenty of brood and bees. While others, apparently having less prolific queens, coupled with the habit of Italians to store honey in the brood-chamber, resulted in the diminution of brood, hence a dwindling of the working force was noticeable. Since this was evidently due to crowding out the queen by long-continued heavy feeding it proved nothing.

In an article on page 729, October 15th, by J. A. Heberle, B. S., of Bavaria, Germany, he quotes Dr. U. Kramer, an eminent scientist of Zurich, Switzerland, to the effect that the weakened vitality resulting from feeding sugar syrup is due to copious drafts of albumen from the body of bees while inverting it. Since the evil effects resulting from the feeding of thin sweetened water are far more sweeping in their devastating effects than is found in the feeding of syrup of greater density it is evident that such a practice, if carried to any considerable extent, will not be without its deleterious effects upon the bees as well as upon the following honey crop; for in view of this convincing evidence no appreciable harm will result from the feeding of sugar syrup of a proper density in any quantity. In my estimation the proper density of sugar syrup for feeding bees under all conditions is $2\frac{1}{2}$ sugar to one of water (boiling).

In view of the disastrous results that are likely to follow the injudicious feeding of half-and-half sugar syrup, as usually practiced, undoubtedly the inexperienced will find it to their interest to refrain from feeding sugar syrup, except as a last resort, to recuperate depleted stores. Personally I prefer solid sheets of candy molded in wired

frames while hot, and placed one on each side, close to the brood-nest. If left too long, however, the candy will be consumed, and combs built in their stead that will be likely to comprise a large percentage of drone-cells. It may be in order to state further that, in conducting these experiments, in every case ample provision was made for storage above the brood-chamber.

Birmingham, Ohio.

HONEY SHIPPED SUCCESSFULLY BY PARCEL POST

BY C. W. DAYTON

Dr. Miller's experience, as stated on p. 333, May 15, and Dr. Moody's experiments as given on p. 653, Sept. 15, do not agree with my experience in shipping extracted honey by parcel post. I have shipped about 300 parcels, and have had but one leakage, and that happened where I put up three 12-oz. soldered cans in a sack loosely, without any other packing material for protection. And even then I believe the tin would not have loosened if it had been soldered as strong as it ought to have been. In soldering there should be enough solder put on to fill the groove nearly, not merely enough to stop the crevice. For 12 or 16 oz. tins I take 14 sheets of common newspaper, 12x8 inches, and wrap it around the long way and fasten with a piece of wire. Then I wrap four of these packages in another heavy wrapping paper and rope them tightly in all directions, twisting the twine at every crossing. I then put on the tag, and the package goes safely. Gallons and half-gallons I am sending out by mail nearly every day, and the recipients write me that there is safe and sound arrival.

The cans should completely fill the box. The gallons and half-gallons are the round-cornered square cans boxed with wood. They have $\frac{5}{8}$ ends and $\frac{1}{4}$ -inch sides, thoroughly nailed. Then I wrap around each end a strong wire and twist it up tight with pliers. Then another short piece is put on for a handle. I also paste on the box my honey price list and a red label giving directions to handle with care. The postmaster also puts the packages in a special sack intended for fragile packages. Beekeepers should look after these affairs when mailing honey.

I have shipped these packages up to 10 lbs. to all parts of the United States and several foreign countries, and have complimentary letters from the receivers of the honey from these distant countries on the safe arrival of the honey.

The finest thing that has happened to bee culture in many a long year is the

parcel-post mail privilege. Beekeepers should appreciate it, since we were so long in getting it.

Owensmouth, Cal.

IS IMMUNITY TO POISON FROM BEE-STINGS INHERITED?

BY W. A. H. GILSTRAP

Neither Mrs. Gilstrap's parents nor mine ever worked much with bees. She has worked with them a good share of the time for 20 years, while I have worked with them for 23 years, which means we were both inoculated with the poison of bee-stings quite a while before we were married, which was 17 years ago. Most of our early work was with the ordinary California mongrel bee called hybrids. They can sting. In her early experience Mrs. Gilstrap was stung half a dozen times one day, which caused her to "break out" as if she had hives, and she was quite sick. In two days she was able to be up and tackle bees again.

Now, you might hunt a while before you would find a woman who likes to work with bees as well as Mrs. Gilstrap, or one who can stand stings as well.

In my early experience with bees the stings were so painful and left so much soreness that I seriously contemplated quitting; but the fascinating nature of the business perhaps had more to do in keeping me with bees than financial considerations did, till I became fairly immune to the poison.

A bee-sting has never been serious with any of our eight children. The most remarkable one of the children in this line is our youngest boy, Percy, who got over a hundred stings above his shirt collar at one dose before he was three years old without any very serious results. Perhaps an account of that affair would be of interest to GLEANINGS readers.

The apiary was south of the house, perhaps 40 to 70 yards, with bamboo on the west and north sides. The south part of the apiary was occupied by scrub bees which I had bought and brought home, killed the queens, and replaced with ripe cells of good Italian stock. From the house I passed along west of the bamboo and entered the apiary at the southwest corner, passing out of the apiary at the northeast corner, in the vain search for a possible swarm. I turned off the road to care for a horse before returning to the house. At the southwest corner of the yard one of those black (or nearly black) bees stung me on my head.

As Percy afterward told us, he followed me through the apiary by sight and could not have been far from me. He passed me

while I was caring for the horse; but I did not see him nor hear him. His mother later noticed that he seemed fretful, and told him to go to bed, which he did, and then he called for a drink. Before the water could be brought from a pump in the yard, he got a cup to get a drink, then said, "Mama, bees hurt me."

"Where?"

"On my head."

She called me at once, and we commenced scraping the stings from his neck, face, and head, where they were closely and rather evenly stuck. His hair was quite short. After removing 35 stings with a dull knife it was clear that I had not removed a third of them while Mrs. Gilstrap was busy on the other side. He cried a little then, and twitched, which made us fear spasms. We put strong soda water on him, gave a little diluted whisky, and phoned from a near neighbor's to a doctor less than two miles away, and took some ammonia back, which was applied where it would do good, but could not apply it in the nose and on the eyes where the stings were as thickly placed as anywhere.

The doctor said we had done about all he could have done. While he is opposed to intoxicating beverages as much as we are or can be, he said the whisky would tend to prevent spasms; but if spasms were once commenced, whisky would make them worse. The face was somewhat swollen for a day or two, and for several days there were dark spots, much like those left from measles. He lost a few hours' play from the encounter.

About two weeks later several of the children were with me with hands, faces, and feet bare, in the Italian part of the yard. Percy got a sting on the foot, probably from stepping on a bee, when he said, "You old bad bee!" then complacently laid down and went to sleep near the hive.

Modesto, Cal.

GIVING BEES A FLIGHT IN MID-WINTER

Providing a Cage in a Warm Room for Emergency

BY DANA F. DOW

I was much interested in Mr. Whitten's article, p. 182, March 15, and your editorial comment on it, p. 170. I have done some winter manipulation of colonies, not for the purpose of breeding them up, but to give needed flights and supply sealed stores.

Winter before last, very cold weather set in the first of December, with the temperature frequently at or below zero. About the middle of January there were indica-

tions that some of my colonies were suffering from dysentery. The fall honey here is principally from asters and goldenrod, and contains considerable pollen, so that bees wintered on it need several flights during the winter.

As there was no prospect of mild weather I cast about for some way of giving the bees in the affected hives a flight. Accordingly I made a framework three feet square and four feet in height, and covered it with common blue mosquito netting. On one side the netting was left very slack and long, and not tacked to the bottom of the frame, thus providing a place to pass a hive and tools or sealed combs into the cage. On the same side two holes were made in the netting, and a pair of bee-gloves were sewed securely to it. The cage was put in the dining-room before a large sunny window, with the slack side turned away from the light.

Sitting on a low stool I was enabled to open a hive and give the bees a flight, supply sealed combs of honey, and perform every manipulation as easily as in summer, and all without a bee escaping.

Before putting a hive in the cage I placed a layer of old newspapers on the bottom, and when the bees came out for a flight the discharge of faeces was something amazing in quantity, to say nothing of odor.

The hive-cover was left partly off; and when the bees were tired of flying, some of them would find the hive and set up a call and attract their companions. By covering the top of the cage with a thick cloth, and allowing the light to shine only near the entrance, all the bees would crawl down and find the hive. Several colonies were short of stores, and I supplied them with sealed combs by this method.

After giving the bees good flights for two days, the next evening I confined them in the hive with a piece of wire netting, and then set the hive in a cold room for a day to give them time to re-form their winter cluster. The next evening I put them back in the outside case on the winter stand and removed the wire netting.

One colony furnished a surprise. It was only a three-frame nucleus in a thin box, and had been left outside and simply covered with old carpeting and boards. As there were no signs of life about it I concluded it had succumbed. However, when the box was put in the cage, and the cover removed, it proved to be literally crammed with bees, and they boiled out full of fight at being disturbed. On taking out the center frame I found a large patch of brood on each side, which was surprising, considering that it was only a nucleus, and had been subjected to severely cold weather for six weeks. This

nucleus made a strong colony the following summer. And here I may say that these bees were Banats, the only ones I ever owned. They were certainly tough and hardy, but I had to get rid of them for their drones were so vigorous that it was almost impossible to get Italian queens purely mated, even with the air filled with drones from twenty-five Italian colonies in the yard.

Several Italian colonies that I examined had a small amount of brood, but not as much as the nucleus before mentioned. Of course it is better to avoid disturbing bees in the winter; but in cases of emergency a cage like the one I have described will meet all requirements, although the height might be somewhat reduced and still give plenty of space for flight.

Ipswich, Mass.

BREEDING FROM IMMUNE STOCK TO GET RID OF PARALYSIS

BY CH. NOEL EDDOWES

In an article, p. 723, Oct. 15, Mr. N. L. Stapleton advocates requeening as a cure for paralysis. I am in accord with Mr. Stapleton as far as that, but I do not agree with him that the queen is not responsible for the trouble. In my experience I have found that the queen has most to do with the trouble, in that her bees are more susceptible to the attacks of paralysis than the bees of a queen that comes from a stock that has not suffered from the disease. I am (as Darwin was) a strong believer in the survival of the fittest; and if a breeder wishes to get the most fit he must select from queens whose bees do not show signs of disease.

In 1905 I bought 40 colonies of bees. When the season came when bees are attacked by paralysis, the apiary was strewn with dead and dying bees so that it was impossible to take a step without treading on bees. I noticed, when examining the hives, that there were two colonies that did not show signs of paralysis. These two queens I picked to breed from. The next year the improvement was marked. I continued to pick my queens in this way until now I rarely have more than one per cent of my colonies attacked by paralysis. But this was not enough, as the supposition had to be proved.

In 1909 I had a queen whose bees contracted paralysis. I reared five queens from her and scattered them through the apiary as far apart as possible. The rest of the apiary was requeened from a queen that I knew was practically proof against paraly-

sis. It was curious to see how the disease picked out those queens which had inherited the constitutional weakness which made them susceptible to its attack. I made no attempt to cure them. One was killed right out; three others were badly attacked, but recovered; one was not attacked. None of the colonies headed by the daughters of the immune queen were attacked.

In 1913 I reared ten queens from a queen I wished to test. I knew nothing of her antecedents, but she had proved herself a good queen and had not shown signs of paralysis. There were 56 colonies in this out-apiary. The rest were requeened from one of my breeders. Paralysis attacked this queen's colony and seven of her daughters, but not one of the colonies requeened from my breeder. I keep a very careful record of my breeders so that I can look up my record-book and know what any queen's antecedents did. The quickest way I know to cure paralysis is to unite a nucleus with a young queen, known to be of immune stock, to the sick hive. The bees of the nucleus will, as a rule, kill and throw out all diseased bees, and the colony will be cured in about a fortnight. I once had a queenless and broodless colony attacked by paralysis. I gave the bees a queen and brood at the same time; and as soon as the brood hatched, and the young bees had taken the place of the old bees, paralysis disappeared.

From my experience I think that paralysis is transmitted from bee to bee so that, when a colony swarms that has paralysis, only the healthy bees go with the swarm, so they start fresh and keep well. I have not found that it makes any difference whether the colony remains without brood for any length of time or not; for when I treat a case I kill the old queen and introduce the new queen at once. If the colony is very weak I give combs of hatching brood.

Mr. Stapleton will find that, if he continues his observations for a sufficient length of time, queens whose colonies have been once attacked are very liable to a second attack. After a beeyard is entirely cured for three months, it is expensive to have to cure it again if the beekeeper's time is worth any thing. Prevention is better and cheaper than cure. Choose immune bees by selecting and breeding from queens whose bees are not attacked; and by continuing this process over a number of years the bees, for all practical purposes, will be immune to the disease. Never breed from a queen if her bees have been attacked by paralysis, no matter how good she may be in other respects.

Government Farm School, Jamaica, Oct. 31.

CONVERSATIONS WITH DOOLITTLE

Continued from page 842.

side, which will be six inches beyond each center of each.

Let us now see how it works. The first glint of morning sunshine reaches the hive just the same as it does the hive with no covering, inviting the bees to the earliest activity, while the workers keep right on at night till the last rays are hid behind the western horizon, thus giving the early and late flight which both the editor and Dr. Miller agree upon. This gives a start and a warmth at all times, looking toward the prosperity of the colony, as no other can. At about 8:30 A. M. the hive goes into the shade, through the projection of the shade-board, and stays thus till about 3:30 P. M., when the sun again warms the hive, helping to carry out early brood-rearing, and not interfering with the labors of the colony in hot weather.

Binding Gleanings

Having had occasion lately to bind several volumes of GLEANINGS and other bee-papers, I thought it might be found useful to others if I told how it was done. The plan may not be perfect, but it is certainly a cheap and simple way of preserving journals for future reference.

After arranging the numbers for the year in consecutive order, commencing with January and ending with the index, the covers and advertisement pages were removed. Next the edges were placed evenly together, and the whole lot then securely clamped between two boards, of which the top one was about $\frac{1}{4}$ inch from the back edges. Three thin oval nails, two inches long, were driven through the papers, level with the edge of the top board, to make the necessary holes. The bottom board is then shifted back a little, and the first nail withdrawn with a pair of pliers.

A length of waxed twine was next threaded through the hole, cut round outside, pushed through again, and securely fastened. After drawing the nails the two other holes were treated in a like manner, thus holding the papers tightly together. The back now receives a thick coating of glue, and likewise a strip of calico wide enough to fold around each side for about half an inch when in position. A heavy weight placed on keeps the journals flat until the glue has dried.

For covers, a couple of stout cards the correct size, and a piece of glazed linen, are all that is necessary. A space wide enough to admit the back of the papers must be left between the cards, to which the green linen is now glued. To fix the cover on, it is merely glued to the back and allowed to set.

Although neat in appearance, card covers are not absolutely necessary; but when dispensed with, a front and back page of GLEANINGS with one of the fine photographs may be pasted on instead.

A. H. BOWEN.

When I first read GLEANINGS four years ago I was surprised to run across Our Homes in an apicultural paper. Since then I have seen the *Farm Journal* and *Successful Farming*, both of which not only guarantee advertisements, but also acknowledge the fact that there is One who is to be thanked for all the blessings we enjoy.

St. Paul, Minn.

Heads of Grain from Different Fields

Extracting from Brood combs in September

October 25 I put my bees in their winter berths consisting of the telescope for each individual hive in which they came through last winter in good shape. I much prefer wintering my bees on their summer stands, as there is always some loss in both the fall and spring, even if one moves his bees only a few feet. So by using the telescope, and leaving them undisturbed, I find it works much better than lurching them. As to cellar wintering I much prefer the summer stands. There is no lifting of heavy hives, no anxiety as to temperature and ventilation. I simply set the telescope over them, and pack dry leaves around them. Then I forget them until about April 1, when the telescope should be removed and the hives examined and equalized as far as it is possible to do so.

I am right now wondering if there will not be a lot of dead bees next spring that now seem to be in good condition.

I have been guilty of a serious error, and I believe many in this State are guilty of the same error—viz., I failed to extract the honey from the brood-chamber in September, spread the brood, place the empty combs in the center, and feed some good sugar. On examining my bees in late September, preparatory to getting them ready for winter, I discovered many hives with no brood, and others with but little. I attributed this condition to the fact that, when the honey-flow from the sweet clover ceased, the queens stopped laying; and when the aster flow commenced, there was but little room for the queen to deposit her eggs, as she had been so crowded with sweet-clover honey. I feel quite sure that I am going to lose a few bees on this account, especially if we have a hard and prolonged winter. So far as I have been able to learn, many colonies of bees are in this condition, and I greatly fear that next spring will find many of us with few bees and plenty of honey.

Indianapolis, Ind. J. F. KIGHT.

[It is of the greatest importance to make sure of the proper proportion of young vigorous bees in the fall. If the conditions are such that the brood-combs are filled solid with honey in the late summer or early fall, so that the queen has no room to lay, possibly it might be best to extract some of the honey to make room for brood reared because of the stimulative feeding later on. However, we think it would be best to start brood-rearing earlier by stimulative feeding so that, in case there is a good fall flow, the lower part of the central combs will still be occupied by brood, which, hatching out later on, will leave a "winter nest."

This whole question is a disputed one—that is, the question of wintering on solid combs of honey or on combs having empty space in the lower part for a winter nest. We suggest that all those who have the opportunity to do so should test the two plans this coming winter and report in the spring, said reports for use in our Sept. 1st issue in 1914.

We doubt whether many beekeepers would sanction the plan of extracting from the brood-nest in September.—Ed.]

Comb Honey Cut to Fit into Sections has a "Stuck in" Appearance

I have read with interest the article by Dr. Humpert, Oct. 1, p. 674, and your remarks on it. I was surprised that you should consider the plan of cutting frame honey into chunks for the bees to fasten in section bases as something of originality and value. Before now you will probably have heard from many beekeepers who have experimented in this line with more or less success—generally less.

Last spring I had more calls for section honey than I could begin to supply. I had a good many

more shallow frames of orange honey than I needed, so I tried to make the bees fasten my chunk honey into sections. I found the best way to get the comb in the sections was to cut it a very little too large, take a folded section, open the joint, slip it over the chunk of honey, and squeeze the dovetail together again.

The bees certainly fastened in the combs; but the results were not satisfactory. In almost every case the cells next to the wood were cut down to (or nearly to) the midrib, and the adjoining ones rounded off to match, and, of course, emptied. Nor could I get these empty cells drawn out and filled again, though the colony I used was an ideal one for such work—a prime swarm requeened with a ten-day-old queen. The brood-nest was packed with honey and young brood, the bees were finishing their first super, a good flow from orange bloom was on, and a big feeder was under them at night. Five days after giving these stuck-in sections the colony swarmed, and the sections still had the stuck-in look, so I cut out the honey again and put it up as "bulk comb."

Some beemen may make a success of Dr. Humpert's method, but my little experience leads me to believe that section honey produced in this way will always have what might be termed a stuck-in appearance, and necessarily so, for the bees must clean out every cell next to the wood in order to do the sticking in, and I am not sure whether they can even stick it without cutting down the walls of the cells somewhat.

As to eliminating swarming, I think I will use the method for making extra-rapid increase next spring.

By the way, I can give a sure method for eliminating tree-climbing for the purpose of capturing a swarm. It is very simple. Let the swarm come out and circle higher and higher until the bees pitch on the uppermost and outermost limb of the only unclimbable tree in the yard; then stand off where you can get a good sight of the cluster, and with a 22 rifle shoot off the queen's wings. You will kill a few of the bees near her, but that will insure her losing her hold and coming to the ground ready to cage. Don't say this is impracticable, for I did it myself last week. True, I was not aiming at the queen, but trying to cut off the limb so the bees would cluster somewhere else, and made a "miss shoot," and cut through the edge of the cluster. I killed about 20 bees, and the queen came down with them with half of both wings shot clear off. She is laying now, and apparently no worse for getting into a shooting-scrape. I would not recommend the plan to a novice; but one with experience in beelore should succeed.

Apopka, Fla., Oct. 27.

HARRY HEWITT.

A. I. Root's Directions for Wintering Bees Given Thirty Years ago

Now that cold winter is about to close in on you in the colder regions, let me repeat the formula that our old friend A. I. Root gave to us (how to winter bees) over 30 years ago. If you, my brother and sister beekeepers, will strictly adhere to the formula I would not be afraid to insure every colony you have to winter without a single loss, providing you have healthy bees and good pure winter stores for them to eat.

Have a double-walled hive, the intervening space filled with oat chaff; a couple of division-boards made of 3/8-inch lumber, doubled-walled, filled with oat chaff, cushioned around the ends and bottom so as to fit the hive tight. Now comes the particular part. Weigh out four combs that will average 15 lbs. of honey to the comb; the best quality of honey possible. Place them in the center of your double-walled hive properly spaced; crowd down your chaff division-boards on each outside. I will add, before you

put in the combs of honey, cut out a circular piece of honey in the middle of each comb about two inches from the top-bar for a winter passage. They will not fill them up during the winter. Now that your combs and division-boards are in, properly spaced off, fill on the outside of the division-boards and inner walls of the hive with oat chaff. Now comes the filling up. Just crowd these four combs with bees until they squeeze out on the alighting-board. Simply have them to fill the entire space. Then lay a small stick, perhaps two, across the frames, about three or four inches apart. Put on your burlap. I will add on my own responsibility three or four newspapers, then your upper story or half-story chaff cushion; then the cover, and you now have a hive of bees that will simply be a sure thing. Father Root gave directions how to make the chaff cushion (burlap): "Cut it so as to have square corners; make it so it will be a little larger than the inside of the hive, so it will be about six inches deep; then fill it with nice oat chaff; then crowd it down tight all around the inside of the upper story or half-story."

I have been handling bees for about thirty years, and in a cold country (until I came here), and I always followed A. I. Root's formula for wintering bees, and yet have the first swarm to lose in wintering.

Well, in this country any old way will do; but they require a whole lot of honey, as they just go to it all winter.

Phoenix, Ariz., Nov. 10.

L. M. BROWN.

Is it Advisable to Take Out Full Combs of Stores and Put in Frames of Foundation in the Fall?

My ten-frame brood-chambers are full of honey. Would it be good policy for me to remove a few frames of honey and replace them with frames of wired foundation? If so, in what part of the hive should I put them—middle, sides, or all on one side?

In the fall, how late should feeding to encourage brood-rearing be continued?

When replacing poor combs by frames of wired foundation in April, should they be put in the center or side of the brood-chamber?

Des Moines, Iowa, Oct. 13.

L. S. EDISON.

[No, sir, 'e. If you have ten-frame brood-chambers full of honey, do not disturb them. We can not see what you would gain by removing a few frames of honey and putting in their place frames of foundation. If they are put in the center of the brood-nest they will be almost worse than nothing unless you feed enough syrup to cause the bees to draw them out, fill, and cap them over. You will then be right back where you started, and in the mean time you will have exhausted the vitality of the bees not a little by the procedure.]

When bees are needing stores, one can feed clear up to and sometimes past the time when frosty nights and freezing weather come on. But it is usually advisable to feed earlier. We have fed after having freezing spells, and have had excellent results in wintering. In our locality we can feed as late as the first of November, and sometimes it is necessary to do it, as an earlier feed will start brood-rearing, causing some of the syrup to be used up.—ED.]

Supplying an Artificial Substitute that will Fully Take the Place of Natural Pollen for Brood-rearing

I am in need of some information regarding supplying bees with pollen, and therefore am imposing on your time as the most direct way of getting it.

In your various experiments have you tried a cooked nitrogenous feed as artificial pollen? If so, would you advise an equal mixture of wheat shorts

or middlings, and cotton-seed meal mixed with honey to make a jellylike mass? Owing to our two dry winters and the freeze last winter, there is a dearth of late pollen-producing plants this fall, and hardly enough pollen in the combs to supply the brood-rearing that usually goes on during the winter. About the same condition prevailed last winter, and the bees built up on orange bloom. For that reason there was no surplus.

Moreno, Cal.

B. W. BROWN.

[You put up a hard question for us to answer. While bees can be fed meal out in open pans at certain seasons of the year, this kind of pollen does not seem to give the results that the natural pollen does from the flowers themselves. We never tried cooking the nitrogenous feed. We have no idea how it would work. We may be up against this proposition in Florida when we move our bees there this winter. Mr. A. B. Marchant, of Apalachicola, thinks he has solved the problem of how to supply the bees with an artificial substitute for pollen in the hives so that the bees will rear brood when natural pollen is not available. Perhaps he will tell us about it. Should you discover any solution of the problem we should be glad to have you let us know through the columns of GLEANINGS.—ED.]

A Further Precaution to Observe when Shaking for Foul Brood

When reading R. F. Holtermann's article on "Shaking Combs of a Diseased Colony," Oct. 15, p. 726, a further method of "minimizing risk" occurred to me. At the time of removing combs not containing brood in preparation for shaking, cage the queen in a cage which can be easily removed from the hive without disturbing the bees. Next day move the hive gently—so gently that the bees are hardly aware that they are being moved, and in its place put the hive prepared with frames and starters. This should be done when the bees are flying freely, and in a short time sufficient bees will have collected to take care of the queen which should now be given them. By evening most of the gatherers will have returned to the old stand, and the young bees left can be rapidly shaken from the combs without the use of any smoke. The second shake can be carried out in the usual way. Of course, if preferred, the queen could be caught early in the morning. By midday the bees, having got over the excitement caused by the manipulation, the hives could be changed, and the young bees shaken in the evening when other colonies had ceased flying for the day. By this method the greater number of old bees would transfer themselves without taking any contaminated honey with them.

B. BLACKBURN.

Hoo, Minster, Ramsgate, England, Nov. 5.

Please advise what success building up colonies on sweetened water, 1 to 9, would bring. It does not seem to do well here.

W. L. WHITNEY.

Cranbrook, B. C., Can., Sept. 29.

[Sweetened water, or a syrup of only one part sugar to nine parts of water, will do very well for outdoor feeders during warm weather. Such a weak syrup as this, however, must be taken up in a few hours; otherwise it is quite liable to sour. A 1-to-9 syrup can not be fed inside the hive unless the bees can take it up inside of 24 hours or less. Something, however, will depend upon the humidity of the atmosphere as well as the temperature. In your climate we should think it very doubtful if you will be able to use the 1-to-9 syrup. You probably could not use very satisfactorily in the hive any thing less than three parts water to one of sugar.—ED.]

Our Homes

A. I. Root

What hath God wrought?—NUM. 23:23.

OUR OHIO HOME; THE BUNGALOW.

A year ago or more I told you that Mrs. Root was finding it too big a task to take care of our large brick house that was just right to accommodate us two when we were younger, with our family of five children; and I told you, too, that she was begging for a little home—one that would not require so much care and responsibility. Before we started for Florida last fall it was inclosed with the roof on; and the children—Mr. Calvert particularly—looked after the finishing up during the winter. When we came back last April the house was all finished complete, as you see it below. The young folks wrote us that our home was ready for occupancy; but it was one of our happy surprises to find it complete, warmed up with natural gas, hot and cold water (and soft cistern water at that) wherever it was wanted; and last, but not least, a pretty well-stocked pantry. Carrie Bell, our youngest daughter, came in next day and asked how we liked our bungalow and its surroundings. I think the reply that I gave offhand sums it up pretty well. I said, "Why, dear Carrie, we find just showers of blessings everywhere."*

Now, after looking at the picture you might care to know something about the inside. There are four moderate-sized rooms on the first floor—a sitting-room, a dining-room, a kitchen, and a bedroom. You might think the bedroom should have been upstairs; but Mrs. Root said she had climbed stairs all her life, and she would like a home so that, after she had passed three-score years and ten, there would not be very much running up and downstairs to do. Besides the four rooms mentioned, there is a pantry and a storeroom in a little wing on

* Will the friends excuse me if I pause right here and speak of something else that may seem a little irrelevant to our subscribers? When Mrs. Root and I formed a partnership we had planned not to have a very large family, if any at all; but "man proposes and God disposes;" and I feel like adding, "Blessed be the name of the Lord." Suppose God had not overruled our poor weak judgment and overruled our plans. I shall have to confess that, as the little prattlers came trooping along, we sometimes thought God was imposing a pretty heavy burden; but where would this beautiful home be, with its loving children and grandchildren, had we been permitted to have our own way?

Now let me go a little further. There are several of you, both men and women, whose eyes rest on these pages, who are not married, although of marriageable age. Perhaps you are preparing to live single. My friends, where would I have been at this moment had I listened to selfish plans and selfish impulses? Does not God know best? and has he not with wonderful wisdom fashioned humanity with infinite love and care after all?

Our bungalow cottage that Mrs. Root and I found finished when we reached our Medina home last April.

the back side. Please notice the first floor is but little above the level of the lawn in front, so there is not much climbing up and down to get in. Well, on the back side the basement is also on a level with the garden, for the house is on a little side hill. The basement floor is really above the level of the ground outside, so that if the water should ever get into the cellar it will run out of the outside door. But that is not likely. The cistern is under the pantry, and is partly under ground and partly in the basement. When we have plenty of rain it can be filled up nearly to the main floor. The cistern is planned so that, by unscrewing a four-inch iron pipe, every drop will run out by gravity; and when it overflows the overflow all comes from the bottom, taking up sediment or whatever may have collected from the rains. Without our knowing anything about it, the children had planned an apparatus to take the water out of the cistern, and drive it, either hot or cold, into a bath-room or the kitchen sink. This is done by the force of the city water, the latter being comparatively hard. If I am correct, the apparatus sends up three gallons of soft water by wasting two gallons of the city water.

Heretofore we two have never used gas for warming or for cooking; and for quite a time Mrs. Root declared she would rather have her old-fashioned Stewart cook-stove. Her main complaint about the gas was that it would never go out of itself like wood for fuel. In cooking with the old stove she had learned to put in just about enough fuel to do the work; and if she forgot about it, it would go out of its own accord. In vain I pleaded that with gas there was no dusty fuel to litter up the house, nor ashes flying around to be brushed up daily.

Before leaving the house, I wish to say a word more about the stairs. Mrs. Root declares she has worn herself out by climbing awkward and poorly made stairways; therefore I told her to have these stairs down to the basement made just after her own notion; and I think I can describe it without any drawing; and I want to add that, if I had to climb basement stairs many times a day, I entirely agree with her. These

stairs are made of just two long two-inch plank. Plain flat steps are let into these plank so as to come just $8\frac{1}{2}$ inches from the top of one to the top of the next; and the plank for the steps are just ten inches wide; but there are no risers to close up the space between the steps—nothing to bump your toes against when you are in a hurry; and this makes it very much easier to sweep them off or dust them off. These stairways are certainly a very important feature in any home, and I would put the matter of looks entirely secondary. Have the stairs easy to use and easy to dust off and keep clean.

Our main cold cellar where we keep our vegetables and fruit is under the north side, and the house faces north. By opening the windows of this cellar during cool nights or cool days, and shutting it warm nights and warm days, we have been able to get along very well without the bother of a refrigerator; and as the floor of this cold cellar is right on a level with the garden, as I have told you, it is an easy matter to move stuff in and out without any climbing up and down. The front porch needs no description. It is all made of cement, including pillars that support the roof. The roof is slate, as you notice, so we have the very best of drinking-water. The picture of the auto-house just below gives you also a glimpse of the east porch. This porch is also of cement, floor and all. If you have never had a porch with a cement floor you can scarcely imagine what a convenience it is to have a floor that can be swept and scrubbed off with nothing that will soak up or hold the water.

The sidewalks which you see in the pictures are made of cement. They cost, all

Our auto-house for that little electric auto I have been talking to you about.

told, ten cents a square foot, made by a firm that has the machinery for doing the best kind of work.

Now about that automobile-house and the electric automobile. Carrie Bell with her two children occupied the seat while Huber took the picture. The building for the electric auto is, as you see, close by the front door; and I greatly enjoy using the little machine to run errands for any of the six families. To obviate the trouble of turning around, Huber invented and installed a very pretty little turn-table. It takes less than a minute to jump out of the machine, grasp hold of the wheel guards, and run it around so it will be ready to start off again. The apparatus for charging the electric battery was installed by one of the grandchildren, Wynne Boyden (13), the elder son of the daughter we called Blue Eyes toward forty years ago.

If you look between the buildings over down the bank, you will get a faint glimpse of the row of evergreens that cut off the west wind from our garden. You can also get a glimpse of the big sunflower that stands close by the dasheen. It got some of the liquid manure that overflowed the dasheens, and I just cut one single head of seed that weighed 9 lbs.

Now I want to close my long story with something about that electric automobile. It was purchased in Cleveland, second-hand, and cost, as it stands, only \$275. It is a Baker electric Stanhope, and cost, when first made, \$1800. They are now offered for sale in the large cities at these low prices because they are somewhat out of fashion. But what does that matter to Mrs. Root and me? The batteries needed renewing when I bought it, and this will cost about \$75.00; but it ran all summer just as we found it, and will run twelve or fifteen miles very well with one charge. With the replenished batteries it is supposed to go about forty miles with good level roads. One trouble with the electric is that, if you try to run over bad or muddy roads, your current will be rapidly exhausted, and you might find it hard work to get home. The electric is so simple that any woman—in fact, almost any child—might run it. When you want to go you just push a single lever. If you want to go faster, crowd the lever further. With good roads it will make about fifteen miles an hour—a little faster than any horse will go; or you can run it on a slow walk if you wish. I have had a great deal to say about God's gifts; and I want to tell you that, with all the blessings that have come to me in the comparatively long life I have been blessed with, there are few things that I thank God more for than

this electric vehicle. It is always ready. It saves my strength. It is always ready to hustle things, without complaining, when important matters crowd. It never tires. It very seldom needs any kind of repair—at least while I can handle it. Let me go back a little.

When I was about twelve years old, and electricity was my hobby, I went to a blacksmith and bought the largest worn file he had on the premises. I had him heat it up and form it in the shape of a letter U. Then I ground off the file-marks and had it tempered, and then I had a big U magnet. A traveling lecturer magnetized it for me. Then I got a little bit of pure soft iron that would almost reach across the poles of the magnet. This was mounted on a spindle or shaft with a coil of copper wire around it, making an electro magnet. With a home-made galvanic battery, after some hard work for weeks or months experimenting, I had an electric motor much after the fashion of the motors that now drive our electric cars and many of our factories. I wanted this motor of mine both to push and to pull; and I got it, and was surprised at the power it exerted. I have before mentioned going around to the country schoolhouses and giving them talks with my home-made apparatus. I predicted, in a boyish way, what was coming. I said it would be in "three or four years." The only mistake I made was that it took the scientific world and our best mechanics thirty or forty years to bring it about. With this explanation you can readily imagine how fervently I thank God for having been permitted in my old age to run errands and help the young folks with this beautiful (and I should say elegant) machine, even if it is a little old-fashioned piece of mechanism.

Somebody has suggested that my beloved auto is not exactly God's gift, just like the honeybee and the dasheen, but that it is a gift from our men of science and men of skill. But, I ask, who gave to our scientific men their wonderful ability and skill to grasp and fashion the lightning of the heavens, and to make it an obedient servant to do our bidding?

"He that hath ears to hear, let him hear."

I have for a long time been watching for some invention that would do for the hearing what spectacles do for the eyes; and although several manufacturers of apparatus for the deaf have claimed they had it, I fear it has not yet come to hand; but I think, however, it is in sight. I hardly need mention that unfortunate people, who are hard

of hearing, have been humbugged and swindled by quack advertisements. I have tested pretty much every thing I have seen advertised; but the most benefit I ever received was from some sort of ear-trumpet. The things that are pushed *into* the ear may, some of them, be of slight benefit under some circumstances; and some are sold by philanthropic parties who will let you take one on trial, for which they charge you \$1.00, and they *keep* the dollar for just letting you "try" a thing that should not cost more than five or ten cents.

For a year or two I have been noticing advertisements of a sort of telephone for the deaf; but I did not think proper to bother with it until I saw a half-column advertisement in the *Sunday School Times*. This was from the Mears Ear Phone Co., 45 West 34th St., New York. After a little correspondence they have sent me two instruments on trial, both operated by dry batteries. The massage aurage is for stimulating the nerve of the ear so the natural hearing may be recovered. The directions are, that when one gets a machine he is to walk up to the clock and see how many inches away the ear must be just to catch the sound of the ticking. Then after having used it for some time (twice a day), keep testing the distance. If you can hear the ticking further away, you are making progress. So far, I can not perceive any benefit from the aurage. The other instrument, the ear phone, certainly makes every thing louder. With this instrument I can hear the ticking of the clock plainly from the further end of a large room. Now, this is certainly encouraging. But the sound of the human voice, although much louder, is unnatural and indistinct, so that so far it does not seem to be of any benefit to *me*. Not only is the ticking of the clock magnified, but every other sound. When Mrs. Root is working with her dishes the clash of the pans and kettles fairly makes me jump. Any thing like the rattle of a tin pan seems to be particularly magnified; and these various sounds make such a din that I can not hear talking as well as I can without an instrument. I may get over this in time, and I am going to make a faithful test.

Now here comes in one of my "wonderful discoveries;" but, like so many of my discoveries, although it is new to me it may be an old thing after all. While experimenting with the ticking of the clock I happened to put my hand up to my ear, as deaf people often do, and I found that, by putting my thumb under my ear and my fore finger back of and over it, and crowding the ear forward (as a horse does when he wants to listen), I could hear the clock

tick plainly clear out in the center of the room. With *both* hands in that position I could hear it tick in any part of the room as well as with the instrument. Now, it would not only be inconvenient but a little ridiculous to think of putting up both hands in that position when I can not catch on to the talk; and I confess, also, that I shrink against publishing my infirmity by lugging an ear-trumpet around wherever I go. I think at the present time I shall get along as I have been doing for a dozen years past—that is, when outside of our home or in the office. In the office I shall use the palm of my hand in the way I have described when I do not hear readily; and my two hands, right and left, I shall take along with me, having them at all times right at "hand." I think this will be much easier and more comfortable, at least to myself, than a dry battery and a receiver, even if the latter is not much larger than a half-dollar.

I have also received circulars from the General Acoustic Co., of New York. Their apparatus costs \$60.00. The ones I have been mentioning cost \$20.00 each, or the two for \$37.50.

Later.—To-day, Nov. 3, just as we are about to start for Florida, I have, by the kind permission of the manufacturers, tested both instruments mentioned above—the \$20.00 one and the \$60.00 one—and I am sorry to say that, although the latter is a much finer instrument, I do not find either one enough help in my case to warrant me in keeping it, and therefore both have been returned. The principal trouble is the clash and clatter of sounds besides the voice that I am wanting to hear. I am assured by both of the firms that in time I would be able to distinguish and would not be troubled by these echoes or clattering, and this may be true. The greatest reason why I can not hear through the telephone is the buzzing and scraping noise. My deafness is a little peculiar. While I hear the voice I do not seem to be able to catch on unless I know pretty well what my informant is talking about. Another thing, I hear ordinary conversation very well without any mechanical help if I can be reasonably near the person who is talking.

I am sorry to make so poor a report, for I have good reason to believe that hundreds are finding these instruments of great benefit.

What a feeling of delight comes over one on returning hot and tired from a long day among the bees, to find GLEANINGS awaiting our arrival! It seems to get better and brighter every issue, while the special numbers are really a valuable addition.

A. H. BOWEN.

High-pressure Gardening

SWEET CLOVER A "NOXIOUS WEED."

Dear Sir:—This statement appeared in the *Geneseo Republic*, Aug. 1, 1913. The paper is printed in Geneseo, Ill.

Colona, Ill., Aug. 1.

C. J. GLENN.

Here is the clipping referred to:

A DANGEROUS PLANT.

The plant *mellilotus*, or sweet clover, with its pretty name and unparalleled vitality, may give mankind the trial of the ages. It probably will prove a scourge worse than war and all other scourges combined, and yet it may give back to the world the nitrogen that our soils are begging for to-day.

In some parts of the world nitrogenous rocks are scattered by the glaciers of the past, and the slow decomposition of these rocks gives a nitrogen supply; but in the great Northwest, where the rocks are covered with many feet of alluvium, the soil is even now in great need of nitrogen food that can come only from plants like sweet clover, red clover, white clover, alfalfa, cow peas, etc.

Mellilotus alba, or white-blossom sweet clover, is the one we are after in this article. There is also the yellow variety (*M. officinalis*), and the common alfalfa (*Medicago sativa*), which are more easily managed and controlled. Sweet clover was first sown broadcast on the roads to feed the bees, and for a time did little harm; but the wagon-wheels have carried it into every road in nearly every State, if not every State of the Union. I have studied it in several States, and have found it close up to the timber line on the Rocky Mountains.

The reason why it has not gone into the fields and pastures more is because the clover bacteria are not in most of our cultivated fields; but it is surely creeping into the fields and pastures, and will soon make the farmers take notice.

I will stake my reputation on the statement that, if one pint of seed with clover bacteria were sown on a forty-acre timber pasture, and a young man were given a scythe, a hoe, and a spade, and hired for life, he could not exterminate it if he lived sixty years. I have never seen a road cleared of it yet. It gains a little every year, no odds how much it is mown down, as mowing is a positive failure. It is a biennial plant, and will produce seed the second year. If mowed ever so much, the lower branches will seed the ground all over and gain a little ground as the nodules in the soil gradually spread. I can show a multitude of roads and lanes so covered that there is scarcely a wagon-track open; and the worst feature is that nothing else grows when *mellilotus* comes in.

If it gets into the fields and pastures as it now occupies the roads and hedges, the food supply of the domestic animals and the human family will be about shut off. It is fast injuring our roads, for no road-grader was ever made that would kill it out on any road. It is a menace to the traveler, for it entirely hides all gullies and ravines, and teams are often floundered in a hidden trench in crossing the road, as it grows six feet high in any poor soil.

Our domestic animals will eat a little sweet clover if starved to it, but they generally pass it by and hunt for other grasses. They will soon hunt in vain. I can show any one thousands of places where it is gradually taking possession, and it will stay until some genius can invent or devise an exterminator to cope with it successfully. Science must come to the rescue now or it will prove to be the problem of the nineteenth century.

If quick relief does not come, the whole human race will be hopelessly enslaved by this fiend of all fiends, this curse of all curses, this wolf in sheep's clothing, this demon in disguise.—L. R. WITHERELL, Knoxville, Ill.

One reason why I have given place to the above is because it so forcibly illustrates how some people, when they get a going, ride their hobbies to death, trampling under foot good common sense, reason, and every thing else. In the second paragraph our vehement friend *acknowledges* that the much-needed nitrogen can come only through the influence of sweet clover and other legumes; then he straightway deplores the kind of "mission work" that the wagon-wheels of our limestone roads are doing. Then again he honestly owns up the need of the clover bacteria which are "slowly but surely" creeping into the fields. Very likely it will be a slow job to eliminate sweet clover with a scythe, hoe, and spade; but, my dear friend Wetherell, that is not the way we exterminate the weeds from fields in our part of the country. When sweet clover does get into the fields, it is the easiest plant in the world to exterminate by simply plowing it under; and it is the very best legume to enrich poor soils that has ever been discovered. In regard to its being an enemy to good roads, it makes one smile to think of that letter in the book we have just printed on sweet clover, that tells about making the very finest kind of roads with sweet clover and spreading it in sandy places. In closing, our friend admits that domestic animals will eat it if starved to it; but he does not add that, when once they get to liking it, they prefer it to any other clover. Either he has never discovered that fact or this ugly mood prevents him from owning it up. Now, my good friend Wetherell, how does it come that you omit all mention of what our experiment stations are just now deciding about sweet clover? And, finally, is it possible that you do not know any thing about the sweet-clover bulletin that the Department of Agriculture of the United States has just been sending out? Your closing sentence that ends with "this demon in disguise" is a big joke, in view of the fact that the agriculturists of the world are just now deciding it is an angel of mercy to the hard-working farmer instead of being what it has been called, a "noxious weed."

Later.—Since the above was put in type, I noticed the article in that excellent authority, the *Country Gentleman*, which was quoted p. 816, Nov. 15.

I might mention here that all or nearly all the agricultural papers are now falling in line, and giving sweet clover the credit that justly belongs to it.

SWEET CLOVER ADAPTED TO POOR LAND.

Please note the enclosed clipping. It looks as if the despised weed was at last coming to its own. I expect to attend this opening; and if I can find any one who has fed sweet clover, or used it for pasture, I will give you the details.

You wrote me some time ago regarding the time the farmers cut their alfalfa. The *thinking* man cuts his after it blooms, as the cured hay has more substance, and is not what is termed washy; in fact, it is impossible to feed cured alfalfa that was cut green (or before blooming) to horses, as it has a very bad effect on their kidneys, and weakens them. It does not seem to affect cattle or hogs. I think that in five years from now half the alfalfa will be allowed to bloom before it is cut.

I look for heavy winter losses on bees this year. Dry weather killed all plant life, and the fall flowers were just nicely started when we had a killing frost. However, it is all for the best, as the majority of those who lose out never give their bees any attention, and that is where half the foul brood comes from.
